This toning process is essentially an intensification, and, should the print be too heavy when intensified, it may be reduced in intensity without alteration of colour, by immersing for a short time in a ten per cent. solution of ammonium sulphocyanide, rendered faintly acid with glacial acetic acid, which dissolves the white ferrocyanide of silver without affecting the uranium salt. This process is particularly valuable for lantern slides, as it leaves only the uranium image, which is much more translucent than the opaque ferrocyanide of silver, hence the shadows are much clearer.

Blue or greenish-blue tones are not much sought after, but they are specially suitable for some subjects, particularly in the form of lantern slides, when they make a welcome change from the interminable blacks and browns.

The same ferridcyanide solution is used, and the second solution is a one per cent. solution of ammonio-citrate of iron with ten per cent. of glacial acetic acid, and these two should be mixed in the proportion of one part of ferridcyanide and one-and-a-half parts of ammonio-citrate. By prolonged immersion the image becomes quite a bright blue, and for lantern slides this looks almost like a stain of an aniline dye if the ferrocyanide of silver be dissolved out with hypo, which has no effect on the blue image.

Numerous shades of pure green or greenish-blue are to be obtained by mixing the ferridcyanide, uranium, and iron solutions in equal parts, and varying the duration of toning.

For a rather rich brownish sepia there is no bath so easy to use as the ferridcyanide and molybdate of ammonia in one per cent. solution, in equal parts, and this has the advantage over uranium toning in that the prints can be washed in ordinary water.

Copper has been suggested as a toning agent for bromide prints, but some prints thus toned six months ago have altered considerably, so that no great reliance can be placed on the permanency of this process. The best method is to dissolve ten parts of acetate of copper in one hundred parts of water, and add sufficient of a ten per cent. solution of oxalic acid to precipitate the whole of the copper, then to pour off the supernatant liquid, and add sufficient neutral oxalate of potassium to dissolve the precipitate, adding enough water to make one hundred parts in all.

An intensification process, which also gives a brownish-black image, is to bleach the image in mercuric iodide solution, and then to treat with a one per cent. solution of Schlippe's salt.

The various methods of lead toning are so unreliable, because of the difficulty of removing all the salts from the fibres of the paper or from the gelatine, and also because of the enormous intensification that they give, that they should never be adopted.

A. D. PRETZL.

## ACTION OF LIGHT UPON METALLIC SILVER.

[Paper read before the British Association, Section B.]

FOLLOWING on the lines of Moser's thermographic observations, it may be asserted that metallic silver is sensitive to light. If cut-out masks be laid upon the surface of silver leaf or foil, silvered glass, or on a Daguerreotype plate, and exposed to the sun's rays, a visible image ultimately becomes apparent on the metallic surface. The effect may, however, be got in a very much shorter space of time if the partly exposed metal be subjected to mercury vapour, or developed by immersion in an acid solution of a ferrous salt mixed with nitrate of silver. Clear images, hardly as yet to be called pictures, can thus be obtained of a permanent character, so that it may be possible to work the Daguerreotype process without iodising the plate. In fact, the photographic phenomena of the invisible developable image, the visible image, reversal, and the effect of pressure marks can all be illustrated on the plain silver surface.

This, at least, is a new discovery.

Copper seems to be sensitive in the same way, and, doubtless, other metals.

P.S.—To avoid contact, a thin sheet of mica was interposed between the silver plate and mask in the experiments without appreciably affecting the result. MAJOR-GENERAL J. WATERHOUSE.

## BLUE PRINTS.

THE ferro-prussiate, or blue process, introduced by Herschel nearly sixty years ago, finds many applications at the present time, the latest of which we gave in our columns last week in the *Foreign News and Notes*. In this instance it is lined on zinc plates in connexion with three-colour printing, but only as a guide to the artist to make colour drawings, as in chromo-lithography or chromo-zincography. There is another "blue process," which is utilised for a somewhat similar purpose, though it is entirely different from that just referred to, and is largely used at the Ordnance Survey Office at Southampton. As it may not be familiar to many of our readers, or, possibly, to some who work photo-mechanical processes, we will give a brief outline of its application.

The Ordnance maps, it may be explained, are all drawn accurately to scale, so accurately, indeed, that in the case of large towns, which are drawn to a scale of a little over ten feet to the mile, even such things as the street lamp-posts are shown at their relative distances apart. From these drawings the maps are reduced to different scales by photography, and printed by photo-zincography. The parish maps are on a smaller scale—a little over twenty-five inches to the mile. Now, it will be seen that, if any of these large scales be considerably reduced, say to one inch to the mile, the finer details, the names of the roads, lanes, &c., would not, by reason of their fineness, be rendered distinctly readable, and consequently they have to be emphasised. That is done in this way. A print on the large scale is taken from the zinc plate in a very pale blue ink. The artist then traces in the finer details, much bolder, in a strong black ink with a ruling pen, keeping a little outside the lines in the original. Then the names are put in on a larger scale—indeed, the map is reproduced in black on a bolder scale, the blue print merely serving as a guide to accuracy.

When all is finished, this map is photographed to the necessary scale, and, as the pale blue ink is of such an actinic colour, it is not distinguishable from the white ground of the paper in the negative. We allude to this "blue process" now, because it serves much the same end as that given in our previous issue, and may be useful to some who may not be familiar with it.

### "LYING ABOUT, CARELESS-LIKE."

We have not heard so much of late about "Darkest Photography, and the Way Out," nor do our papers fill up with the financial woes of the poor struggling professional photographer. We must take it, I suppose, that things are jogging along in the usual way; if it does not run to sausages for supper, at least there's bread and cheese. I have often wondered what amount of good resulted from these agitations, whether any professional benefited to the extent of a shilling. But, as Kipling says, that is another story, and, as the office boy puts it, "things as is, is," and from this latter emphatic utterance there's no getting away, no way out. We have to face every day the business of that day, and, to get on, we must see that it is done properly. It is of no use saying with the Editor of this paper, "It shall be done," if we do not put our shoulder to the wheel and push.

Now I've arrived at the point I wanted. It is not only the business of each day that we must attend to, but our eyes must be always wide open for extras. Do what has to be done, of course, and anything else that presents itself in addition. And here let me say that I am not writing these few lines for Vandyke Fitzjabbars, Esq., artist, or John Millais D'Ancy, art photographer, each with their art galleries and decorated reception rooms who do nothing under 2l. 2s. a copy, and so on; who will only operate by special persuasion and provided they have not a bilious attack. No, it is the ordinary or common garden professional to whom I want to say something. True, even he may turn up his nose at it, and in that case let it turn.

I have upon more than one occasion taken down to one or other of our metropolitan societies a match box or a cigarette case containing in the front a photograph; and I have gone so far as to suggest that there might be a little business in this sort of thing. The usual criticism I have so far met with is that it would be *infra dig.* Well, now, I feel in for a dig at some of our plodding professionals, that they do not keep their eyes open for extras. "What! sell match boxes?" they cry; "crushed snakes, what next?" But suppose, good sirs, a customer picked up a match box, admired it, and asked where he could get one like it, would it be asking too much for you to say that to oblige him you would put his photograph in one? You see I am putting it very mildly, as I have no desire to trample upon your feelings more than I can help. But, then, forsooth even an artist uses matches, and it would not be too utterly barbarian if a box should just chance to be handy for the convenience of a customer.

But, then, what about ladies? They don't smoke, you say, and—well, the less I meddle with that matter the better. But there's no harm in confessing that *all* my cigarettes are not smoked by—myself. That's diplomatic, I think. Well, even for ladies the matches might be taken out and pins inserted. No one can go wrong on pins, they are a female commodity of considerable importance, whether the double barrel variety for the hair, or the sharp-business-pointed-keep-everything-up sort.

I'm afraid in my old age I am getting rather Abraham Bogardus. But to come to the point. There are a number of metal boxes now sold with glass lids, and the commoner kinds are made oblong and round, and in about four sizes each. They are intended for the exhibition in shop windows of small things, such as drawing pins, hair pins, collar studs, &c. They are strongly made, look very well when new, and cost but little. A little frame of metal, readily removable, holds the glass in position. Now, it is the easiest thing in the world to squeegee down a silver print upon the glass, and at once we have an extra not to be despised by any one. The round patterns are more suitable for ladies' use, but those I have used for some years now fit in very well for gentlemen. The smallest size is a wax match box, the next a card case, and the largest a cigarette case. I have had one matchbox in use for five years, and a cigarette case for at least three years. Even if the glass breaks, it is easily replaced. The prices of the boxes are approximately 2d., 3d., and 4d. each, bought singly, but, of course, by the gross it would come out much cheaper.

The sight size of the cigarette case is  $3\frac{1}{2} \times 2\frac{1}{4}$ , very nearly an ordinary C.D.V. print. And may I put it before you how nice a small vignettéd carte head looks in this framework, one of those heads you pay 6d. for when you put the retouching out, with the postage extra. Poor girl, she has to stipulate *that* extra. Just think how pleasant the surprise at receiving from the man sweetheart a nice pin box with his photo, or from the female sweetheart a convenient cigarette case with her portrait. In matters connected with unmarried people especially, you professional photographers need to keep your eyes wide open, there's money in it.

You buy a little box for a little 4d. and sell it for a big shilling say, meanwhile you have merely printed an extra copy of a dozen order and stuck it down to the glass instead of mounting it. *Infra dig.* Where does it come in? You please a customer and pocket the shilling, that customer comes back and you pocket more shillings. Surely *infra dig.* can be swallowed at a shilling at a time.

I have sent the Editor one of these boxes for use as a cigarette case, and, as I should do were I a professional photographer, I have inserted in the lid a photograph that is interesting to the recipient.

Christmas is coming again this year, and for gifts these things are

most suitable. Local views could, of course, be utilised, but it is in the personal the application lies.

So have some of these boxes lying about, careless-like, on the table. You'll find them pay you. WALTER D. WELFORD.

### DOUBTFUL TENDENCIES.

(Paper read before the North Middlesex Photographic Society.)

PHOTOGRAPHY, as most of you are aware, was originally discovered by the Chinese some five centuries before the Christian era, just previous to the discovery of the mariner's compass, gunpowder, wireless telegraphy, and several other useful inventions, which, though lost at the fall of the Bang Foo dynasty, have fortunately been rediscovered in modern times. A hand camera found in an Egyptian tomb, and the interesting ruins of a dark room at Pompeii, show that the Western World was familiar with this art. The only reference to photography in any classic author that I am aware of is that beautiful passage in Juvenal, "Camera obscura lignea ect, bonus bona bonum." This apparent lack of interest in the subject amongst the Latin poets is perhaps explained by the fact that, beyond a few photographers burnt by Nero for snap-shooting him, no encouragement was given by the State to this beautiful art. At the fall of the Roman empire the art of photography was lost, and there was no knowledge of it till its rediscovery at the beginning of this century, when a student of the Chinese language, deciphering the inscription on an ancient tea-chest, gave to the world the long-lost art; this happened at Margate, and the earliest experiments were conducted on the sands of that popular seaside resort, which have ever since been a rendezvous for photographers, the leading professionals usually making them their headquarters during the summer months.

In the early days of the revival there was developed a certain amount of ill feeling between artists and photographers, owing, no doubt, to the extreme modesty of the latter; but, as this gradually wore off, the artist recognised in his rival a pleasant comrade, ever ready for an adjourned meeting or a *willie waught*. *Willie waught*, I may remark, is German for whisky, and it is this agreement in taste regarding special Scotch that has cemented the friendship between the two professions. Of late years all has been well between them, with the exception, perhaps, of a little irritation shown by a certain artist and critic who has been troubled in mind because of photographers signing their productions; but even this gentleman was satisfied when it was explained to him that the signatures were only there in case the pictures got lost, and were written large because they might happen to fall into the hands of short-sighted people.

Despite a few such trifling differences, we have gone on in a friendly way, although the photographer, with his usual modesty, has laid claim to all the discoveries in modern art, and, out of sheer bashfulness, thinks that the artist is for ever copying from him. We have overlooked this, we have possessed our souls in patience. The artist may not be modest, but he is patient. That, too, is a virtue; but our patience has been sorely tried of late, owing to the discovery of a strange and mysterious process which has caused, sir, some of your craft to forget even their modesty. You have been kind enough to allow hitherto that the painter has still some slight claim to precedence, but now he holds it no longer, since the invention of this weird and wondrous process.

You must forgive me going into technical matters, but I must briefly explain this process to you. Some paper is taken which is sensitised with blacking and gum mixed in unequal parts; after the usual exposure, or a little more or less, as the case may require, the picture is removed from the frame, then laid in hot water, and developed with a scrubbing brush. This is a very difficult operation, and it is said by some to work easier if accompanied by a little profanity. This, I believe though, is not absolutely necessary. The result is impossible to foretell, but of one thing you may make sure, the print will be nothing like the original negative. I may remark, for the guidance of the young bichromatist, that a print from a negative taken at noonday usually has the effect of midnight, but whether foggy, snowy, stormy, or fine, I cannot, of course, say, as this depends largely on the stiffness of the bristles in the developer, and the strength of the language used. I have here two samples of the gum process. I will not criticise them. I must say, though, that I don't think the *best* gum can have been used. I will pass them round to you, accompanied by two photographs from the same negatives; they serve to illustrate my remarks as to the change of weather and time of day. Since the discovery, or rather revival, of this process, many carbonaceous and unintelligible smudges have been brought into being, and have astonished and delighted those who produced them. I am speaking rather strongly about this process, rather too strongly, you may think, for one who has no practical knowledge of photography. I confess to having seen a few effective pictures produced by it—effective, though not really convincing, and, of course, I may be wrong in my strictures. It may possess capabilities of which I am ignorant, but, judging from results, it produces work that is, to my mind, vague and meaningless,

and without any excuse for being. Whether this is the fault of the process or the worker, it is not for me to decide. I have seen, since I wrote this paper, some gum pictures that closely resembled ordinary carbon prints, mere ordinary photographs, you know, but, of course, these do not come under my criticism, as I am dealing only with high art. Say what you will, a smudge is a smudge, whether it be a pleasant one or not. If you threw eggs against a black fence, you would soon have some erratic, and perhaps pleasing, decoration, but it would not be art. Now, this phase of photography, if we may call it photography, along with a deal of work of the same kind, marks certain tendencies which I have taken the liberty of calling doubtful.

Though photographers are ready to claim a large share in the advancement of modern art, they are apt sometimes to forget that the artistic application of photography has sprung from the study of painting; but, however this study is pursued, it should leave the photographer a photographer. I have chosen the gum-bichromate process more particularly for my abuse to-night, because I feel that in many of these productions the photographer has not felt the necessity of this, and, now that he is able to produce something that is eminently unlike a photograph, he is pleased to think that he has become an artist, and is ready to enter the lists with those who have bound themselves in a lifelong apprenticeship to art. I would point out here that the great and insurmountable difference between painting and photography is not, as is vulgarly supposed, that one is done by hand and in colours, and the other by a chemical process, but that one is the result of the light rays falling upon a sensitive plate, and the other of their falling on a sensitive brain.

Art in its highest form is not a copy of nature, but nature tinged with human personality—in the great picture we have a new view of nature, a view from a fresh standpoint. That a good photographer will stamp his work with a certain amount of individuality I do not deny, but ask yourselves to what extent he may do it as compared with the painter? The painter, I think, has a right to speak strongly against these gum pictures and kindred work, because they are in many cases merely copies of his effects.

Modern art, especially as represented in the school known as the Romantics, has shown us a subtle appreciation of nature that is called somewhat vaguely "quality;" this consists of a suggestion rather than an exact portrayal of nature, and is marked by looser and softer forms than in the more precise art of the past. This, of course, has made it easy for the copyist. The young painter has been long in the field; he soon discovered that his water-colour rubbed with a sponge or sandpaper, or his oil-painting scraped down with a palette knife, had a dim resemblance to the quality got by the modern masters. We have all tried this sort of thing, just as a donkey runs down every blind-alley before he will condescend to trudge along the high road. We recover in time, however. Gum, by the bye, is not quite so sticky as it was a short time ago. The invention, or rather revival, of the gum-bichromate process gave an opportunity to those who were tired of following in the beaten track for trying something original, which, like most other original things nowadays, is just a crib from something else. We have been deluged with impressions in painting, but the wildest, strangest, weirdest impression of all is the carbonaceous one that, with name in corner written larger than ever, is brandished before us, whilst its maker proclaims from the house-top, "I am an artist!"

There may be something pleasant about the mere look of the thing, something fascinating in the rich velvety darks and the wayward spots that are scattered around like the stars in the Milky Way, but personally I prefer photographs. I have seen on these walls, and in the London exhibitions, a great deal of interesting and sincere work that I frankly admit is art. It is photographic art, though, and is certainly not to be confused with painting or drawing, for these mean greater control over method and material than is possible to the photographic worker, and yet, curiously enough, the approximation to the artist's work, which is claimed by some, has been reached by this process, whose principal element seems to be chance. If a photograph is to be modified or altered in any way, the process should be sufficiently under control to make the picture the result of the worker's judgment and feeling. If it be not so, then there is no art displayed and no credit deserved.

I do not think there can be much control in the gum process. If there is, then the pictures I have seen hitherto must be the result of downright deliberate wickedness, and are a strong proof of universal depravity. In other processes, too, there is the same tendency to impressionism. I maintain this is simply imitation of the painter.

Impressionism in its true sense is the most difficult and dangerous part of a painter's craft. It is the getting the very essence out of nature. A true impression looks full—fuller and richer than what is styled finish.

We are told that Millet, the French peasant painter, kept digging away at his pictures when every one else thought they were finished, simplifying them. The most wonderful part of Turner's work is the slight water-colours of the late period. Using the word impression to mean the simplest and broadest painting, it will, of course, include the noblest and greatest drawing, but the usual meaning of the word is the subservience of form to colour. To take, therefore, photography, the chief charm of which is its exact portrayal of form, and to smudge and destroy this form with nothing to put in its place, with no other object than

copying those painters who are inimitable, is an utter waste of time and effort.

I can sympathise with those photographers who are trying to destroy aggressive detail, to keep broad and simple masses. We often see this done successfully, and it can be done without going to the extreme of a wholesale sweeping together, which results in blurred edges and empty dark masses. You must remember in painting there is colour, and it is colour mainly that gives that indefinable quality that in the broadest work is often more satisfying than the greatest drudgery of academic finish. A true impression lacks nothing, except what it is better without. We cannot always say this of the photograph. Let me give a common enough example—a seascape with bright sky, dark sails, and hulls of boats and reflections. In many of these impressionistic photographs the sail, hull, and reflection are the same in tone and quality. Do not, in your efforts after dignity, ignore the slight, but necessary, differences between these things. To throw them all into one is absurd, and yet that is what is done by the gum process, and we are then asked to admire the rich darks.

Coming back to the tendencies again, I may class this very doubtful one and some others under the head of copying painters' effects without having found what they mean by them, and whether they can be rendered by photography at all. If the idea is to be unphotographic, success is often attained, for we are shown prints where everything that is most beautiful and interesting in photography is marked by absence. Let me give you an instance. Harking back to our much maligned process again, at times the blacking is left out, and some brown or red pigment takes its place, and the result is the suggestion of a bad chalk drawing that has been carried in the pocket for some weeks, and, what is so extraordinary, it resembles a bad drawing in the respect of want of form. Things become lumps, and you may often mistake a boat on the seashore for a cow in a clover field. This last statement you must not take quite literally. It is what the newspapers call *on dit*, which is French for a lie; but what I mean is that these things are really bad. Now, what does this mean? I should say that we have been looking at some modern drawing, and, seeing a wonderful effect got by apparently loose and careless touching, off we go for our gum and blacking, and the job's done. But let us remember that behind every quick touch in the drawing was the master's hand, disciplined by long labour, and touched by the gods with cunning beyond the rest of mortals. Nothing is more deceptive than the simplicity of consummate art, but its apparent easiness will mock the strength of our best hours.

You will have already discovered that my tendency is towards wandering. You will excuse me, therefore, saying a few words here on texture.

A highly polished surface is still a source of delight to the greater part of the public. Varnish is like charity, and covers a multitude of artistic sins. A smooth picture will win praise before one in which the brushmarks are shown. There is some reason in this. Roughness for roughness' sake is false. Not many years ago brushmarks were a sort of trade mark on pictures. We used at school to revel in So-and-So's brushwork—of course, in the best pictures you don't think of rough or smooth. They just look right; the roughness in painting was a reaction from the old smooth dead painting of the early Victorian period; and also because paint dabbed on and let alone has a finer quality than when it has been dragged about.

Photography seems still suffering from such a reaction. First we had everything glossy and smooth, but now it is all pimples. The painter, if he uses a rough canvas, may kill the grain where he likes, or, if he works on a smooth one, may make texture just where he pleases; the photographer having to be content with one texture, the grain of his paper, which will show equally all over, it behoves him to choose that judiciously, according to the subject. It has surprised me to see sometimes very beautiful work quite spoiled by coarse granulated paper. This seems curious, but fact or fashion over-rides judgment. Canvas-grained paper or any other peculiar surface may be sometimes used with good effect, but great care is needed, or the result is displeasing. I am afraid the real state of the case is that some successful work is done in some particular way, and there is a rush at once to copy it. Your modesty, no doubt, forbids you admitting this impeachment, but I confess it is so amongst painters.

I wish to-night to treat all the bichromatists who may be present—I'm afraid that's an error—oh, I see—treat them with Christian charity, because I must confess that I myself used to admire these peculiar productions. There is something pleasant about them at first sight, but imagine living with them. Fancy coming home at night, perhaps a little exhilarated, and catching sight of the fantastic shapes. Good heavens! have I got 'em again? but I will draw the veil. Perhaps, though, it is in the seeing double stage when these pictures appeal to the beholder, when to the sober man they appear only foolishness. This may be so. We will not experiment with it, however.

The photographs that give the most lasting pleasure, and I see a good many that, hanging on our walls, would be a source of quiet delight every time we looked at them, are those where the worker, without any affectation or ambition to overstep the limits of his craft, has got hold of his process, and been content to get all the expression he could out of it. Technical excellence must be considered, the particular advantages of the process brought out, and the picture must look, even to the un-

initiated, as if it were the result of thought and care, and not of chance. I am afraid I am slanging things to-night, but any one outsider who takes an interest in photography must blame or praise this peculiar phase of it; it is not to be passed over in silence.

If these things be experiments I would hold my peace, but, if experimental, they should be put into folios or the waste-paper basket, and not brought out as masterpieces.

There is but one test for art, and that is sincerity. It must be begotten of sincere admiration, and produced with sincerity of purpose. If art possesses sincerity, we can respect even where we cannot admire. We must be watchful and ready to receive every new truth, but, on the other hand, we must be careful—and it is one of the great dangers of our modern life—we must be careful not to welcome as a bursting forth of light those things whose only claims to notice are novelty and peculiarity. Hardly a day passes now but we are treated by the press to the discovery of a great artist or poet, whose name will awaken, perhaps, for a moment an echo in the silence of eternity, and we flatter ourselves on the keenness of our perception, but, if a real prophet should be sent us, we should receive him as in the past with indifference or with scorn.

Sincerity is the only test, for art is too wide to be compassed by rules or canons. The crowd that passes through the picture gallery looking for the prettiest will inevitably miss the best, but from honest men sincerity will ever receive respect, which usually ripens into admiration. The old art still stands because it is sincere, and some of the modern for the same reason will endure, though the names that are oftenest in the papers may be forgotten.

Now what is sincerity in photography? The first thing, I should say, is that your work should be a photograph, a literal transcript of nature. Is nothing, then, to be modified or altered in the result that your camera gives you? Yes, to a certain extent. When you bring home your negative, I hope that you bring home, too, a vivid recollection of the scene, and some idea of what you are going to try for in your print; if not, it is no good trying to improve what you have got. Now, I maintain that anything is legitimate that will help you to produce the effect that you are aiming at. You may by knowledge and various methods of treatment get a more pleasing and truer picture than you would otherwise have obtained. I see no objection to hand work even, within reasonable limits—anything you like save fudging. I know it is vulgarly supposed that in painting some very fine effects have been got by fudging, but nothing worth doing was ever done that way. I have used the expression literal transcript in regard to your picture. I do not wish to narrow the bounds of photography, but I would point out that there are bounds, and very firm ones too, for you have brought in nature to help you, and she may bear a little guidance, but will not stand being driven. The light rays under your judgment and good taste produce your picture, you endeavour with limited means of modification to bring this piece of nature's handiwork into agreement with your view and ideas of the scene. This may sound to you like a truism, but it needs enforcement to-day, when there are those about who wish to produce pictures on a photographic basis, and not really photographs. I mean by literal, therefore, that your picture is to be the effect under which the negative was taken, not merely an effect, however pleasing, for the simple reason that you do not start with a free hand. Stand out in the fields with a clean canvas and a flat full of brushes, and you may paint your dreams if you can, but, when you put your head under that black cloth stick to facts, because you must.

I have been told seriously by some photographers that they use their camera as a painter uses his brush; well, they may think they do. Now the bichromatist not only believes this, but a denoted sight more, for he gives himself a licence that a conscientious painter would not think of taking. He messes about till he gets something, but whether he had any idea at starting of what that something was to be is another matter; it is not enough that a thing be brilliant or clever-looking—it must be true to be convincing. If you see something in nature, and try to get it and fail, no matter. You are nearer getting it to-morrow, but don't trust to luck. A good painter would not begin a morning subject, and, if he mess it up, turn it into a night piece. He might by chance get something by doing so, for there is flaking in everything, but it does not want much knowledge to detect it from real play. There are many hazy ideas about to-day that would be better cleared away. One of the pathways to knowledge, according to Confucius, is to know not only what we do know, but also what we do not know. Now, in practical work, before we can make much progress, we have to find out what we can do and what we cannot do, and if gum and blacking should be the means of bringing home to any of us what we cannot do, they will have fulfilled their mission, and we shall be able to go back to photography sadder but wiser men.

It is such a delightful task finding fault with your neighbour, especially when you can persuade yourself that you are doing it for his good, that I feel I must have one more slap, not only at the bichromatist—but at all those who cultivate fuzziness. The judicious softening of certain parts is perfectly legitimate, but to make everything blurred and undefined just for the fun of the thing can only be part of that depravity that is still knocking about in Adam's offspring. The wicked, who have always an excuse ready, will plead some of the great modern painters. Well, go and look at them, and see how much real drawing underlies their soft edges.

HORACE MUMFERY.

## EXHIBITION STATISTICS.

Now that the doors of the Royal Photographic Society's Exhibition have been for some time thrown open to the public, it may be of interest to our readers if we examine, more fully than has hitherto been done, certain figures relative to the number of exhibits and exhibitors at the several exhibitions held during the past four years. It may thereby be possible to gather some information as to the progress or otherwise of the show. The comparisons do not include the exhibits in the Apparatus Section.

Taking, in the first instance, the broad facts of the number of exhibitors and the number of exhibits shown, we get the following table:—

Year.	No. of Exhibitors.	No. of Exhibits.
1896	160	368
1897	172	449
1898	185	429
1899	165	375

From this we see that this year the figures have practically gone back to the level of those of 1896, the difference being merely that of five exhibitors more with seven exhibits.

The year 1896, we believe, was one in which a drastic selection was made by the Committee appointed for the purpose, and it would seem that this year the duties intrusted to the similar body had been quite as rigorously carried out. This is naturally a surmise, but, as we glean from other sources that the numbers submitted were in excess of those for several years past, we can only form two conclusions, viz., either that the standard set was exceptionally high, or that the average of the work rejected was low, and we are inclined to think that the former was the case, judging by the high all-round quality of the work now hanging on the walls.

Still further analysing the number of exhibitors into those who are members of the Society and those who are not, and their respective number of exhibits, we arrive at the following result:—

Year.	Members.	Non-members.	Exhibits by Members.	Exhibits by Non-members.	Average by Members.	Average by Non-members.
1896	71	89	160	208	2.25	2.34
1897	64	108	165	284	2.58	2.63
1898	78	107	202	227	2.59	2.12
1899	72	93	163	212	2.26	2.28

Perhaps the most striking feature in these figures is once again the similarity that those for the present year bear to those for 1896 in every detail: as regards members, who differ by one only, while the number of their exhibits differ by three, and also in respect of non-members, who differ by four only both as regards themselves and their exhibits.

The years 1897 and 1898 are also noteworthy for the preponderance of non-members, and for their similarity in number.

Taking the average number of exhibits shown by both classes of exhibitors, it is certainly a striking fact that it should work out so closely, there being only a difference of 0.51 between the highest and lowest figures.

Turning now to the number of pictures shown by individual exhibitors, we observe that by far the greater proportion are shown by those who have one, two, three, or four frames accepted, the actual distribution being shown below:—

	1896.	1897.	1898.	1899.
Exhibitors with 1 exhibit .....	75	70	71	77
" " 2 exhibits .....	36	45	55	36
" " 3 " .....	20	17	29	23
" " 4 " .....	14	15	13	13

This accounts for 263 exhibits in 1896, 271 in 1897, 320 in 1898, and 270 in 1899, the resemblance to 1896 being once more noticeably exemplified.

Besides these there are several exhibitors who show 5, 6, and 7 and more pictures, these accounting for the balance of the exhibits, the greatest individual number this year being 19.

Of the total number of exhibits the proportion received from abroad is very small, the figures being 25 in 1896, 50 in 1897, 42 in 1898, and 41 in 1899, by far the largest number coming from the United States, viz., 13, 27, 22, and 20 in each year respectively; Italy sent 11 in 1897, 7 in 1898, and 14 this year, this 14, however, representing only 2 exhibitors. Germany supplied 1 in 1896, 4 in 1897 and 1898, and none this year,

Austria 2 in 1896 and 1897, and 4 in each of the two successive years. This year India sends 4, while other countries made up the totals by units.

It appears to us to be somewhat noticeable that more exhibits are not attracted from abroad, inasmuch as the Royal Photographic Society is the leading Society in the world, and in this connexion it would be interesting to know how many frames are actually submitted to the Committee and thus establish what proportion of them come up to the required exhibition standard.

Still further analysing the exhibits, we find that the numbers received from the provinces, as distinct from those sent by persons residing within the county of London, were 155 in 1896, 178 in 1897, 190 in 1898, and 189 in 1899, the distribution of the exhibits into the three categories specified being as below:—

	1896.	1897.	1898.	1899.
From abroad .....	25	50	42	44
„ the provinces .....	155	178	190	189
„ the metropolis .....	188	221	197	142
Total .....	368	449	429	375

Here we have one of the first points of marked dissimilarity between the years 1896 and 1899, which have, we have shown, been otherwise very much alike, that is to say, the increase in the number from the provinces and the decrease in those from the metropolis.

This increase since 1896 of the number received from the provinces is a distinctly encouraging feature, and tends to show, we think, the growth of pictorial workers outside London.

Formerly there existed very few opportunities for provincial workers to keep themselves in touch with the growth and changes in pictorial work, but of recent years much has been done in this direction by the exhibitions, such as those recently held at Bradford and Derby, as well as by the Invitation Sections which has become a feature of most of the provincial shows.

Possibly this drop in the number from the metropolis is merely incidental, but it strikes us it is a point certainly worth noticing, and it remains to be seen whether the same feature will be as prominent in the future.

Examining in more detail the sources of the exhibits from the provinces, we observe that, with the exception of the present year, when she ties with Liverpool, Birmingham has supplied more frames than any other of the large towns, though the number now forms considerably below that of last year.

The actual figures for several other places as well are as below:—

Town.	No. of Exhibits.			
	1896.	1897.	1898.	1899.
Birmingham.....	18	23	43	28
Liverpool .....	12	10	21	28
Glasgow.....	8	11	10	6
Tunbridge Wells .....	5	15	10	6
Leeds .....	6	9	10	10
Manchester .....	1	4		1

We will not touch upon the figures as to printing processes employed, these having already been analysed by two of our contemporaries, but will merely remark that the two most permanent and elastic methods, viz., platinum and carbon, still hold sway, in spite of the claims which have been advanced for other presumably newer and more facile processes.

We may further remark as to the Exhibition itself that the number of small frames is not so great as in former years, there being an apparent tendency to make larger prints, due possibly to a wider knowledge of the use of the enlarging camera, necessitated, we should judge, by the use of a hand camera by men who formerly had used a stand camera and obtained prints sufficiently large in themselves to be able to be exhibited without enlargement.

A consideration of the artistic qualities of the pictures does not fall within our province in this article, being done elsewhere, so we will conclude with a hope that the facts here adduced may prove to be of interest to those of our readers who are fond of detail, not only in their negatives but in other matters also.

#### MELODRAMA'S NEWEST DETECTIVE.

Out of the bourne of time and space has passed one of the most famous figures in melodrama—killed by the onrush of modern science. I refer, says the Paris correspondent of a Sunday contemporary, to the murder-detector and overhearer of all secrets. Every one knows the man. He was frequently Irish, and always wanted to sing and dance during three

acts instead of up and saying what he knew, and so putting an end to the misery of the heroine, and the large, triumphant smile of the villain. Yes, he passed quietly away at a Paris theatre. Those responsible for his demise are M. Meynet and Mme. Geoffroy, and the scene of the incident was laid in *L'Auvergnate*. The play was made up of little bits of all sorts, and was thoroughly amateurish. But the moment came when you held your breath. The wicked woman had committed a murder, and had so cleverly arranged matters that an innocent man was as good as on the Place de la Roquette at break of day. It was no use looking down the programme to find the name of the man who would step forward at the right moment and denounce her, because you could account for each one's time when the crime was committed. One wondered and waited, and the good folk who patronise the theatre seemed inclined to form a committee to go up on the stage and explain matters for no audience in the world takes so serious a view of common justice as does that of the theatre. Suddenly came the click, click, of the cinematograph, and the damning proof of guilt rolled out before your eyes. It is hardly worth asking how it came about that a cinematograph was in the middle of a park when the murder was committed where it could have only been engaged in taking still life. The effect was remarkably dramatic, and, had a skilled playwright led up to this *dénouement*, *L'Auvergnate* would have had a big run before it. Even as it is, the main idea is a vast improvement on old traditions.

#### COLOUR PHOTOGRAPHY AT THE CAMERA CLUB.

THE lecture season at the Camera Club opened on Thursday, the 5th inst., when Mr. Sanger Shepherd was announced to give a paper upon Photography in Colours. The subject is such an interesting one that it attracted a far larger audience than is generally found at the opening nights of the season.

The first note sounded was one of sadness, for, before commencing the business of the evening, Mr. Godfrey, the energetic Hon. Secretary of the Club, made a feeling allusion to the death of one of the earliest members, Professor W. K. Burton, who for many years past has found his home in Japan, after which Mr. Godfrey gave a sketch of the lecture arrangements for the winter, and was able to describe a very varied programme, which included a number of well-known names. The Chairman (Major-General Waterhouse) then said a few words of introduction for the lecturer, and Mr. Sanger Shepherd commenced what proved to be a very interesting discourse.

The lecturer said that the Secretary had accused him of coming before a critical audience under false pretences, for the members expected to have a paper upon the production of a photograph in the colours of nature, and they were to be put off with a kind of back-door method of solving the problem. This was to some extent the fact, but he thought that they would all be interested in the modification of the three-colour system which he was about to describe, a system which, at any rate, would enable them to project upon a screen coloured slides which were far in advance of anything which could be produced by means of brush and pigments.

It was now generally acknowledged that all the colours of the solar spectrum could be counterfeited with sufficient accuracy to deceive the eye by employing screens to filter the light which reaches the sensitive plates in the camera, these screens being respectively red, blue, violet, and green in tint. By employing screens of different colours in the lantern, and associating them with positives obtained from the three-colour negatives, and by carefully regulating the amount of light projected through each, it is possible to get, with fair success, all the tints found in nature.

It is true that the gelatine plate does not translate the luminosities of the different colours as they are seen by the human eye, and it is necessary that the colour screens be adjusted to the particular plates in use. The effect of printing through various coloured screens was shown.

Mr. Shepherd next dealt with the presentation of positive images in colour, and showed how the best tints to employ for the work which he was about to describe were yellow, blue, and magenta, and he demonstrated, by means of three coloured discs, how these colours, when made to overlap, would produce a complementary tint to each. He then threw upon the screen three separate images, being the copy of a Japanese fan, the first consisting of the yellow portions, the second of the greenish-blue, and the third representing the red portions of the original. These three images were then thrown superposed, giving a representation of the original fan in all its proper tints.

Having thus shown what the method was capable of, the lecturer went into details of manufacture, prefacing his remarks with the statement that the Cadett spectrum plate was the best for the purpose, and that, now that Captain Abney had devised a means of making the coloured screens to actual measurement, they can be supplied at a reasonable price. Indeed, the pioneer work had been performed, and now it was possible for all to profit by it.

The negatives can be taken in an ordinary camera by placing the proper coloured screens in succession in front of the lens, and giving, say, ten secon for the blue, twelve for the green, and fifteen for the red; but the employment of separate dark slides was a nuisance, and in practice it was better to use one long plate for the three exposures, each

third of which was covered by its own colour filter. A convenient form of camera which Mr. Shepherd had employed was shown, in which the pressure of a pneumatic ball three several times, checking each exposure by a watch, did the necessary work. This form of camera has, however, been superseded by something better.

The ideal form of instrument is one in which the three exposures can be made simultaneously, and many ways have been proposed whereby this desideratum may be brought about. One of the first was devised by Du Hauron, a very early worker in the field of colour photography. Its principal feature was a pair of interior semi-transparent mirrors, which occupied the centre of the camera like an inverted A. By this means a direct image was cast through the mirrors to a plate at the back, while the front mirror reflected another image to a plate on the ceiling of the camera, a third image being reflected from the back mirror to a plate on the bottom of the camera. As it was almost impossible to regulate exactly the right amount of partial silvering in these mirrors, the camera did not find extensive employment. Mr. F. E. Ives modified it, but with scant success. Mr. Sanger Shepherd has since taken it in hand, and by placing in the diaphragm slot of the lens a circular screen, which is red in the centre, but allows other rays to pass through its margin, and by opening the iris diaphragm during exposure so as to permit all rays to pass in turn, he has made this form of camera into a practical instrument, and it will, in its improved form, be presently placed on the market.

Means will also be presently commercially available for the production of three-colour lantern slides in the issue of special plates, or, rather, celluloid films of extreme whiteness and transparency. These films will be sold ready-sensitized with a special bromide emulsion, and the purchaser will resensitize them in a half per cent. solution of bichromate of potash, just as he would a piece of carbon tissue. The development will consist of immersion in warm water, leaving nothing on the clear celluloid but a transparent image in relief.

The three prints from the negatives having been made in this way, each one is treated with its proper dye, and it then only remains to bind the three together in proper register to form the coloured lantern slide.

Mr. Sanger Shepherd entered into all the details of the method, which we have only been able to treat in a general manner. It is quite evident that the process is an attractive one and capable of very fine results; it is, too, far more simple than any other which aims at accomplishing similar effects.

The paper received much attention, and the discussion which followed its reading resolved itself into a series of questions, which Mr. Sanger Shepherd was good enough to answer with much detail. A vote of thanks to him terminated the proceedings.

#### MR. E. R. ASHTON AT THE CAMERA CLUB.

THE latest one-man show at the Camera Club, Charing Cross-road, W.C., is the work of Mr. E. R. Ashton, whose collection of forty Egyptian and other Eastern photographs makes one of the most attractive displays that we have for some years seen at the Club. It may be said that for a considerable time past Mr. Ashton has passed his winters in kindlier climates than our own, and this has given him the opportunity of showing by photography, views of Oriental life, customs, and scenery, possessing those elements of charm and mysticism which attract many who, like ourselves, have not looked upon these scenes, as it were, first hand. Photographically, Mr. Ashton has pursued one idea unflinchingly, and, like all men endowed with this rare quality of continuity of purpose, has succeeded to the highest extent in what he has attempted, that is, to show, by means of the camera, how life is lived in the land of the Pharaohs.

Besides this feature of Mr. Ashton's collection, one other is apparent, namely, the consistently high quality of the work throughout. Mr. Ashton, it will be seen, is not the producer of a good photograph here and there, diluted with a great amount of mediocre productions, as is too often the case in these one-man exhibitions, but gives us a singularly level, as well as a good, selection. We are conscious that, in each of the photographs which he shows, Mr. Ashton has used the capabilities of his lens, plate, and printing process to the best advantage.

Scarcely any phase of Cairene life appears to have escaped Mr. Ashton's attention, and we have heard Oriental travellers say that he is to be congratulated on having been enabled to penetrate with his camera buildings into which Mohammedans have strong objections against the admission of unbelievers. The bazaars, the schools, the mosques, the pyramids, the Nile, characteristic bits of architecture, figure studies, land and water-scapes are treated. In his figures Mr. Ashton seems to us very successful; one feels, indeed, that they are natural, while the sentiment of the subjects appears to be distinctly suggested. As the printing processes are not mentioned, we must content ourselves by saying that generally Mr. Ashton leans towards warmth of tone. It is a decidedly interesting exhibition of pure photography that Mr. Ashton has got together; indeed, in the Camera Club just now, one seems to find oneself being transported in imagination to the banks of old Nile with all the historical glories which cluster round the very mention of the word Egypt. Photography of this sort deserves encouragement, and we hope Mr. Ashton will give us more Eastern work.

#### DINNER TO DR. P. H. EMERSON.

ON Thursday evening, October 5, Dr. P. H. Emerson was entertained to a complimentary dinner by a few friends, on the occasion of his visit to London during the present month. The scene of the festivity was the Restaurant Frascati, Oxford-street, and the chair was occupied by Mr. Thomas R. Dallmeyer, F.R.A.S., Vice-President of the Royal Photographic Society. In addition to the guest of the evening there were also present Mr. Thomas Bedding (vice-chairman), Mr. James A. Sinclair, Mr. H. Vivian Hyde, Mr. Fred. Marriott, Mr. Philip Everitt, Mr. E. J. Wall, Mr. H. Snowden Ward, Mr. Percy Wood, &c.

The health of Dr. Emerson was toasted in graceful and appropriate language by Mr. Dallmeyer, who briefly traced the guest's career in photography, and the very great services he had rendered to it. The year 1885 witnessed Dr. Emerson's abandonment of the profession of medicine, in which a successful career undoubtedly awaited him, for the purpose of studying the pictorial possibilities of photography. This work was undertaken in Norfolk and Suffolk, and, as they knew, resulted in many utterances, illustrated by photographs, which carried out Dr. Emerson's teachings. Those teachings were to be found in his book, *Naturalistic Photography*, published in 1889, which revolutionised ideas till then prevalent on the subject of picture-making by photography. In later years Dr. Emerson's work had been singled out for the very great honour of the Progress Medal of the Royal Photographic Society, of whose Exhibition he had also acted as Judge. After other remarks, in the course of which the Chairman assured the guest of the evening of the very high esteem in which his name and work were held in the photographic world, Dr. Emerson's health was drunk with full musical honours.

In reply, Dr. Emerson thanked those present for their kind reception. It was some years since he had been in London, and he had taken the opportunity of visiting the two photographic exhibitions now open. He was very much disappointed with what he had seen. He could detect no advance at either exhibition, save in the framing. The R.P.S. show was certainly the better of the two. With regard to the Salon, in his opinion Demachy's work was simply imitation of that of French painters, and his fan and similar subjects were copied from the bon-bon boxes. There was no sincerity in Mr. Horsley Hinton's work, which was frequently a travesty of nature and vulgar. Dr. Emerson strongly deprecated the imitation of painters' work by means of photography. The latter, he pointed out, had a power of rendering delicacy of gradation not possessed by painters, and, if photographers only availed themselves of that power, photography would certainly hold its own.

After other toasts, a pleasant evening was brought to a close in the usual loyal manner.

## Our Editorial Table.

#### THE "MACKENZIE" DAYLIGHT SLIDE AND ENVELOPES.

Manufactured by Mackenzie & Co., 15-17, Douglas-street, Glasgow.

We have had an opportunity of practically testing this new system of daylight changing, and found it exceedingly convenient and reliable in practice. Let us quote the manufacturers' description of their system of using enveloped dry plates in daylight changing:—

"The envelope is composed of stiff, light-proof cloth, and is made in two parts, an inner and an outer one. The plate is inserted between the grooves of the inner part and covered with a flap, and, at the uncovered end of the plate, is inserted into the open end of the outer part.

"The slide is made of book form, one side being fitted with the usual sliding shutter. The envelope containing the plate is laid within the slide on the shutter, which has a groove near its end to engage with a bar on the covering flap of the envelope. The other side of the slide is fitted with a spring to keep the plate in position, and has an opening covered with celluloid, by which any number or mark on the envelope may be read; it also shows if the envelope flap works properly when the shutter is drawn and closed.

"When the slide is placed in the camera and the shutter drawn, its groove, engaging with the bar on the envelope flap, draws it and the flap off the plate and rolls it up within the slide, and on the closing of the shutter recovers the plate. The envelope and its plate can then be taken out of the slide and placed in the pocket." We are bound to say that we are extremely pleased with this system of using opaque envelopes for daylight changing, and can recommend it to those who are seeking a simple means of film or plate-changing with dark slides.

#### SPECIMENS OF PHOTO-CERAMICS.

By Edward Lee, 10, Midland-road, Leeds.

THE specimens of burnt-in photographs on earthenware slabs which Mr. Lee has submitted to us are exceedingly cheap, and should appeal to photographers desirous of introducing this form of reproduction to their clients. Mr. Lee adopts a modification of the dustin-gon process, and produces his results, either plain or tinted, on china, earthenware, opal, or glass, with glazed or matt surfaces. Besides being cheap—as an example, six cabinet "photo-ceramics" are supplied for 12s. 6d.—the results are attractive to the eye and should command considerable vogue.

## THE RATHENOWER LENSES.

Wholesale Agent: HENRY F. PURSER, 33, Hatton-garden, E.C.

Mr. PURSER has been good enough to lay before us specimens of the most recent lens productions of the Rathenower Optische Industrie lenses, for which he is agent. These comprise a wide-angle; a casket or universal set, and a projection lens for cinematography. An examination of these instruments shows them to have a very high degree of optical finish, and to be admirably adapted for their respective purposes.

The wide-angle series works at  $f/15$  and the angle included ranges from  $100^\circ$  to  $105^\circ$ . As an illustration of the capabilities of the series, we may say that the No. 3, with a focal length of  $7\frac{1}{2}$  inches, covers a  $9 \times 7$  plate with a medium stop, and with the smallest a  $12 \times 10$  the circle having a diameter of 20 inches. The performances of the cinematograph projection lenses may be understood from the following details. The No. 2 has a diameter of  $1\frac{1}{2}$  inches, an equivalent focus of 2 inches, and at distances of 6, 12, and 18 feet enlarges 38, 76, and 114 times respectively. For cinematograph purposes the series should be very useful; like the wide angles, the lenses are exceedingly cheap and are well finished.

Amateur and professional photographers alike will find great utility in the Universal sets. These sets are of the Periscopic Spectacle Lens type.

Series I. consists of four lenses, and Series II. of seven, with varying foci from 6 inches to 30 inches, which makes possible, in the case of Series I., 14 combinations, and in Series II. 29 combinations.

This very great variety of focal range and combination easily provides the photographer with a complete set of lenses for practical work on both near and distant objects. The sets cost 2l. 19s. 6d and 3l. 10s respectively, and are provided with yellow glass diaphragms. No better value could be desired for pictorial purposes. We are very pleased indeed with the excellent properties of the Rathenower lenses.

## THE "KRISTAL" PLATES.

B. J. Edwards &amp; Co., The Grove, Hackney, N.E.

The Kristal plates have been introduced for lantern slides, stereoscopic slides, and transparencies by contact printing. They admit of exposure to weak daylight or bright artificial light, and development by weak actinic illumination, such as gas or candle-light, and thus give the lantern-slide or transparency maker increased convenience in the practice of this beautiful branch of work by relieving him of a certain amount of dark-room imprisonment. We append the principal instructions for the manipulation of the Kristal plates, which, like all the productions of Messrs. Edwards, are sure to be popular:—

The plates may be exposed, under a negative in an ordinary printing

frame, either to subdued daylight or bright artificial light, such as a good paraffin lamp or gas-burner. The time of exposure will vary according to the colour desired in the finished transparency. For black tones a shorter exposure is required than for warm tones, about one and a half to two minutes at a distance of four inches from the flame of a good gas-burner will usually be found sufficient for black tones. Thus with a negative of ordinary density one inch of ribbon burnt at a distance of sixteen inches from the printing frame will give a good black tone. With a thin or weak negative the distance should be increased, or a dense negative may be printed at less distance from the light. For warm or sepia tones use four inches of magnesium ribbon at the same distances. The plates may be safely developed and handled by ordinary candle-light or in a room lighted by gas, no dark room being necessary. Care should, however, be taken not to bring the plates too near to the light, and to avoid, as far as possible, the light falling directly on to them. A sheet of white paper laid upon the table will reflect sufficient light to judge when the development is complete.

The plates must not on any account be exposed to daylight either before or during development.

## DEVELOPER FOR BLACK TONES.

Hydroquinone .....	120 grains.
Sulphite of soda .....	2 ounces.
Carbonate of potash .....	4 "
Bromide of potassium .....	40 grains.
Water to make .....	20 ounces.

For use, mix one part of the above with one part water, and pour directly over the exposed plate. Development should be completed, if the exposure has been correct, in about two minutes.

## DEVELOPER FOR WARM OR SEPIA TONES.

Eikonogen .....	45 grains.
Hydroquinone .....	15 "
Sulphite of soda .....	240 "
Carbonate of potash .....	120 "
Bromide of potassium .....	20 "
Citric acid .....	30 "
Water to make .....	20 ounces.

For use, take one part of the above and one part water. With this developer and sufficient exposure development should be finished in four to five minutes. Should this time be exceeded, owing to under-exposure of the plate, the colour will be darker and not so good. To obtain a rich, warm colour, a full exposure is necessary. Very warm or red tones may be obtained by still further increasing the exposure and diluting the developer.

As soon as development is finished and the details of the picture are visible, the plate must be plunged at once into the

## FIXING BATH.

Hyposulphite of soda .....	4 ounces.
Metabisulphite of soda .....	$\frac{1}{2}$ ounce.
Water to make .....	20 ounces.

After three or four minutes' immersion in this fixing bath, the transparency will be perfectly fixed and cleared. It must then be rinsed, and the surface carefully wiped with a tuft of wet cotton-wool, and then washed in running water for at least half an hour, or for the same time in repeated changes of water; seven or eight changes at intervals will be sufficient. The transparency is then ready to be dried in a cool place free from dust.

## "HYDROQUINONE BR."

A. &amp; M. Zimmermann, 9 &amp; 10 St. Mary-at-Hill, E.C.

UNDER the name of "Hydrokinone BR" another new developer has recently been placed upon the market, and a sample has been submitted to us for trial. It appears to be a bromine derivative of hydroquinone, and it is claimed, apparently not without good grounds, to possess the good qualities of hydroquinone without its characteristic defects. We used the formula given in the directions for use:—

## Solution A.

Hydroquinone BR .....	$\frac{1}{2}$ ounce.
Soda sulphite .....	4 ounces.
Water .....	25 "

## Solution B.

Potassium carbonate .....	3 ounces.
Water .....	25 "

Solution A 5 parts, solution B 5 parts, water 4 parts.

Our trials were made with some rather stale plates of a very popular extra rapid brand and some orthochromatic plates. The results obtained speak highly for the future popularity of the developer. The process of development proceeded steadily, we might almost say deliberately, and the operator can thus decide with certainty when to stop development. The negatives were characterised by a full scale of gradation and free

from the harshness of contrast associated with ordinary hydroquinone development. Both kinds of plates gave negatives free from fog and stain, although we had purposely selected the rapid series for their staleness. We also used the developer for some gas-light development paper, and obtained some excellent prints.

The developer was used for several plates in succession and we did not find much loss of energy. Left standing in a measure for forty-eight hours in the dark room, it had only acquired a pale straw colour.

A developer with the good qualities this seems to possess should soon become a favourite with photographers.

#### PHOTOGRAPHY IN A NUTSHELL.

By THE "KERNEL." 155 pages. Illustrated. Price 1s.

London: Iliffe, Sons, & Sturmer, Limited, 3, St. Bride-street, E.C.

In sending us for review a copy of the new issue of *Photography in a Nutshell*, Mr. W. Tylar points out that the book has been greatly rewritten and brought up to date. This 5000 issue now makes 33,000 copies of the work printed, and, out of the present issue of 5000, nearly 2500 have been sold before delivery from the printers. Mr. Tylar adds that he has recently had an application from a firm in India to reproduce some of the book in the Indian language. Excellence of get-up, variety of illustration, and, above all, a wealth of well-selected information about the practice of photography, should make the latest edition of *Photography in a Nutshell* popular. "The Kernel" (General Hawkes) and all concerned may be congratulated on the continuous success of the book.

#### CHRISTMAS MOUNTS FOR 1899.

Marion & Co., Soho-square, W.C.

We have only to say that the list of Messrs. Marion's mounts for 1899 extends to eight closely printed pages to give our readers an idea of the extraordinary variety of shape, size, and design which is at their disposal. Some samples of these mounts from midget to cabinet size, which we look forward to making practical use of at the festive season, have been kindly sent us by Messrs. Marion, and we can only say of them that they are exceedingly refined in design, tint, and shape, and should do much to enhance the popularity of the photograph as a Christmas card. On the latter subject Messrs. Marion truly remark that it is becoming so customary to mount photographs on cards, for the purpose of sending to friends at Christmas, that the ordinary form of Christmas card is being rapidly superseded. So wide-spread now is the practice of photography that such a revolution is of very great and general interest. Our professional readers should profit by this hint and push the Christmas card business amongst their clients.

In sending us samples of his new Christmas card mounts, Mr. Wilfrid Emery of 8, Dyne-road, Brondesbury, N.W., asks us to state that he prints from customers' negatives, and undertakes the work completely or supplies the cards only as may be desired. The cards are of tasteful design.

#### CATALOGUE RECEIVED.

Thorn & Hoddle, 1, Tothill-street, Westminster.

This catalogue is devoted to a description of apparatus for acetylene lighting and should be in the possession of those photographers contemplating taking up this form of illumination. There are special installations designed for studio work, and the application of the light for lantern purposes has not been lost sight of. Acetylene is probably only in its infancy as yet, and Messrs. Thorn & Hoddle are to be congratulated on their efforts to bring the undoubted qualities of the light before photographers.

## News and Notes.

A CAMERA Club has been formed in connexion with the Camborne School of Mines, the object being to devote attention to photography as applied to mining, surveying, &c. The officers elected are:—*President*: W. Thomas, C.E., F.G.S.—*Vice-President*: A. B. Beringer.—*Hon. Secretary*: H. W. Halifax.

On Wednesday, October 4, Mr. Thomas Fall, F.R.P.S., delivered a lecture on "Photographic Experiences" before a large and appreciative audience of the Borough Polytechnic Photographic Society. Mr. Fall's partiality for animals, especially dogs, was amply demonstrated by a fine collection of slides, whilst his descriptive anecdotes, given in a characteristic, confidential, and "chaty" style, were highly entertaining and amusing.

THE POLYTECHNIC.—This (Friday) evening is the opening night of the Photographic and Process Trades Classes at the Polytechnic, 307-11, Regent-street, W., Mr. Martin Cohn will take the chair, and will give an address on "The Present Position of Three-colour Work, and its Aspect in the Future." The syllabus and particulars of the winter classes in all branches of craft instruction in photography and process has been issued by the Polytechnic Institute, and may be obtained on application at the address given.

PHOTOGRAPHIC CLUB.—October 18, at eight o'clock. Nomination of officers for ensuing year. Paper by Mr. W. Thomas.

MESSRS. PENROSE & Co., 8 and 8A, Upper Baker-street, Lloyd-square, write: "We have pleasure in informing you that the whole of the first edition of the *Process Year Book* was sold out immediately on publication, and a large part of the second and final edition, which will be ready on October 16, is already bespoken."

At a meeting of the Plymouth Mercantile Association, one of the speakers (Mr. Luxton) complained of the manner in which local photographers, and those who produced view books, neglected to show the commercial and naval importance of the place. They might take their pictures of Plymouth Sound, for instance, when there were vessels in it, which would show how truly commercial the place was.

ROYAL PHOTOGRAPHIC SOCIETY.—Tuesday, October 17, at 5A, Pall Mall East, at eight p.m., Mr. Henry W. Bennett will read a paper upon "Architectural Photography." The following lantern fixtures are arranged for the Pall Mall Exhibition: Monday, October 16, "Travels in Italy, Spain, Algeria, &c." by Mr. H. Little; Wednesday, October 18, "A Holiday in North Wales," by Mr. J. A. Hodges; Saturday, October 21, "Bite by the Way," by Mr. E. Dockree, and "Byways of Italy," by Mr. J. C. Ashton.

THE South London Photographic Society will be favoured on Monday, October 16, by Mr. W. F. Fenton-Jones with a lecture entitled "A Swiss Trip." Any one interested will be welcome at the Hanover Hall, Rye-lane, Peckham, at eight o'clock. This Society has fixed the date of their Eleventh Annual Exhibition for March 3-10, 1900, both days inclusive, and have again secured the Camberwell Public Baths. Particulars and entry forms can be obtained of the Hon. Secretary, Mr. F. Goddard, Woodlands, Vanbrugh Hill, Blackheath.

THE CRIPPLEGATE INSTITUTE.—A photographic class for men only, conducted by Mr. C. W. Coe, will be held every Friday from date at the Cripple-gate Institute, Golden-lane, E.C. The course includes eleven practical lessons in development, printing, and toning, &c., specially arranged for amateurs. The fee is 10s. per course. 1, Introductory; 2, Apparatus and Lenses; 3, Plates and Exposures; 4, Lessons in Development; 5, Development; 6, Printing Processes; 7, Finishing and Toning P.O.P.; 8, Bromides and Platinotypes; 9, Enlarging; 10, Mounting and Finishing; 11, Defects and their Remedies. Tickets are now ready at the Clerk's office of the Institute at the address above given.

Re FRANK KNIGHT, photographer, Castle-street, Luton, Beds.—The above-named debtor came up for his public examination at the last sitting of the Luton Bankruptcy Court, before the Registrar. Replying to questions put by the Official Receiver, the debtor stated that he would not have been in his present position if his real property had realised the amount he expected. He commenced business as a photographer at Dunstable two years ago, and he had also been engaged as an agent for the sale of magic-lanterns. Subsequently he removed his business to Luton. Some three years ago he became responsible for a sum of 400l., but he eventually arranged with his solicitors to pay it off. He had never kept a proper set of books of account. Whilst in business in Dunstable, he speculated in real property, and that property was now on his hands. He gave 500l. for the property, and he had a mortgage on it for 400l. He had had some good seasons at the photographic business, but last year was "messed away." He first became aware of the fact that he was unable to pay his creditors 20s. in the £ when he was sued by a creditor for 30l. He owed Messrs. Marion & Co. 22l. 10s. for photographic materials purchased when he opened the Luton business. He would have paid them, but he was pressed by another creditor, so he paid him instead. If his Luton business had turned out as well as he anticipated, he would not have been in his present position. The debtor was eventually allowed to pass his examination.

## Patent News.

THE following applications for Patents were made between September 25 and September 30, 1899:—

DARK SLIDES.—No. 19,221. "An Improvement in Construction of Photographic Dark Slides." J. CORLETT.

STIPPLING PROCESS.—No. 19,363. "An Improved Process for Producing Stippled or Grained Photographic Pictures Directly from Photographic Negatives or Diapositives." R. WIDMANN.

STANDS.—No. 19,367. "An Improved Stand for Cameras, Geodetic Instruments, and the like." Complete specification. C. P. GÖRZ.

APPARATUS.—No. 19,396. "Improvements in Photographic Apparatus." J. E. THORNTON.

PLATE-HOLDER.—No. 19,472.—"Improved Photographic Plate-holder and Changing Apparatus." H. O. FOERSTERLING.

PLATE-CHANGING.—No. 19,473. "Improvements in and connected with Catching Apparatus for Exposed Photographic Plates." H. O. FOERSTERLING.

PHOTOGRAPHS.—No. 19,474. "Improvements in and connected with the Production of Photographs." Complete specification. H. O. FOERSTERLING.

PLATE-CHANGING.—No. 19,475. "Apparatus for Sliding Plates into the Exposing Chamber or Camera of Photographic Apparatus and Removing the Plates after Exposure." Complete specification. H. O. FOERSTERLING.

VIEW-FINDERS.—No. 19,593. "A New or Improved Optical Appliance for use in connexion with View-finders for Photographic or other Purposes." A. L. ADAMS, W. MALLETT, and C. W. BEEVOE.

SELF-TONING PAPER.—No. 19,633. "An Improved Self-acting Toning Paper." O. RATHEL.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
16.....	Birmingham Photo. Society	Excursion to London, to Visit the Exhibitions of the Royal Photographic Society and the Photographic Salon.
16.....	Bradford Photo. Society	What we See in an Old Church. S. Marguerison.
16.....	Camera Club	A Clumber's Holiday in Lofoten. Howard Priestman.
16.....	Kingston-on-Thames	Photography of Flowers. H. T. Malby, F.R.P.S.
16.....	South London	A Swiss Trip. W. Fenton-Jones.
17.....	Birmingham Photo. Society	Recent Advances in X-ray Photography. J. F. Hall-Edwards, L.R.C.P., F.R.P.S.
17.....	Gospel Oak	Exhibition of Prize Slides.
17.....	Hackney	Demonstration of New Wellington Film. Harry Wade.
17.....	Redhill and District	Platotype Printing. F. Marton Duncan.
17.....	Royal Photographic Society	Architectural Photography. Henry W. Bennett.
18.....	Orocydon Camera Club	Opening of Exhibition by Sir Frederick Eoridge, J.P.
18.....	Photographic Club	Paper by W. Thomas.—Nomination of Officers for year.
18.....	West Surrey	Official Visit to the R.P.S. Exhibition.
19.....	Camera Club	Clouds and Photographic Landscapes. James Cadett.
19.....	London and Provincial	Demonstration: The Wellington Film. Harry Wade.
20.....	Ashton-under-Lyne	Elementary Photography Class.
20.....	Orocydon Microscopical	Lantern-slide Making. J. A. Hodges.
21.....	South London	Excursion: Battersea Park. Leader, C. H. Oakden.

### ROYAL PHOTOGRAPHIC SOCIETY.

OCTOBER 10,—Ordinary Meeting.—Sir H. Truman Wood, M.A. (Vice-President), in the chair.

#### ILLNESS OF THE PRESIDENT.

The HON. SECRETARY, having read a letter from the President, stating that he was slowly recovering from an illness which prevented his attendance at the meeting.

The CHAIRMAN said he was sure it would be the wish of every member of the Society that the Hon. Secretary should express to the Earl of Crawford their extreme regret at the cause of his absence, and their hope for his speedy restoration to complete health. The Society owed a great deal to Lord Crawford, who, notwithstanding the many interests which made calls upon his time, had devoted himself loyally and earnestly to its welfare, and whose excellent judgment and tact had been of the greatest advantage in many important respects.

#### BUSINESS OF THE SOCIETY.

Four new members were elected, and forty-five candidates were nominated, the Chairman remarking that no more convincing evidence could be afforded of the satisfactory position which the Society now occupied.

The HON. SECRETARY read a statement of recent presentations to the Society, which included a list of signatures in connexion with an attempt to secure a barony for Fox Talbot, on condition that he relinquished his patent rights (presented by D. J. Leyton, Esq.); and also Mr. T. H. Dallmeyer's Focometer, described to the Society some months ago, and now presented by him.

It was announced that the Polytechnic Photographic Society had been admitted to affiliation.

#### THE LATE PROFESSOR BURTON.

The CHAIRMAN gave sympathetic expression to the loss which the Society had sustained by the lamented death of Professor W. K. Burton, to whose sagacity and energy he paid eloquent tribute. The death of two other members of the Society, Messrs. H. C. Heinrich and Peter Thellusson, was also regretfully alluded to.

#### THE SOCIETY'S NEW HOME.

The HON. SECRETARY stated that the Society had received a very handsome donation of 100*l.*, in connexion with the Guarantee Fund for the new house in Russell-square, from the Maharaja Pradyot Coomar Tagore, an Indian prince in Calcutta, and an enthusiastic and clever photographer. The Council had decided to devote the amount to the purchase of the new book-cases required for the library, and had directed that a brass plate should be affixed to them, recording the fact that they were the gift of the Maharaja.

#### LANTERN EVENINGS—A NEW DEPARTURE.

The HON. SECRETARY also announced that it had been decided to hold an additional meeting on the first Tuesday in each month, when lantern lectures will be given, and at which lady visitors will be especially welcomed. The first lantern evening will be held on Tuesday, November 11, at the Exhibition Gallery, 5A Pall Mall, East, when Mr. J. J. Vezey will give a lecture on "Some Medieval Towns of Germany," with illustrations from photographs by Commander C. E. Gladstone, R.E.

#### PRESENTATION OF MEDALS.

The CHAIRMAN, in proceeding to present the medals awarded to exhibitors at the current Exhibition, remarked that the difficulty of awarding medals appeared to become greater year by year in consequence of the heightened standard of excellence. He thought that, if half a dozen fully qualified experts were each asked to make a list of awards, the six lists would be entirely different one from another, and that few pictures would receive more than two or three votes. Whether this opinion pointed to the advisability of abolishing medals altogether was a question for individual consideration, and he thought

the Council would do well to consider whether the time had not gone by for the recognition of merit by the award of medals. At the current exhibition the Society's medal was awarded to Mr. Dudley Hoyt (No. 21, *Head of an Old Man*), Mr. John H. Gash (No. 130, *Summer Shades*), Mr. W. T. Greatbatch (No. 139, *The Miller's Workshop*), Mr. C. F. Inston (No. 191, *After Rain*), Mr. W. R. Bland (No. 217, *In Wirksworth Church*), Mr. E. G. Boon (No. 273, *Sunny Pastures*), Mr. J. M. Whitehead (No. 276, *Roses*), Mr. A. Stieglitz (No. 299, a vignette in two colours), Mr. J. H. Player (No. 333, a copy of an etching by absorption process), Messrs. J. E. Johnson & Co. (No. 388, an engraved screen plate, 200 lines per inch), and Mr. E. Sanger Shepherd (No. 393, Trichromatic Light Filters). The Chairman presented a medal to Mr. Sanger Shepherd, who was the only exhibitor present who had received an award, and the Hon. Secretary was requested to forward the other medals by post.

#### THREE-COLOUR PHOTOGRAPHY.

Mr. SANGER SHEPHERD showed, by means of the lantern, a series of very beautiful slides in natural colours from three-colour negatives taken through the light filters exhibited by him, the slides being made by superimposing positives on very fine celluloid, the prints from negatives through the red screen being stained by a greenish-blue dye, those from the green negatives being stained pink or "minus green," and those from the blue negatives being stained yellow or "minus blue." Most of the slides were photographs of orchids and butterflies, and all were much admired for their delicacy and accuracy of colouring.

#### PRINTS ON GOLD AND SILVER.

The HON. SECRETARY showed a plate of silver on which a visible image had been obtained by exposure under a rectangle of black paper, from which it was separated by a mica screen in which his initials had been cut. The plate had received no treatment whatever, either before or after exposure: the image of the paper mask and the edges of the mica screen were visible on the plate, but gradual darkening of the whole surface was noticed. General Waterhouse also showed similar effects on gold leaf and silvered glass, the images in certain cases having been developed with mercury.

#### COMING EVENTS.

October 17, "Architectural Photography," by Mr. H. W. Bennett. October 24, "The Wellington Film," by Mr. H. Wade. November 7, Lantern Evening (See above). November 14, the Traill Taylor Memorial Lecture, "Teaching of the Daguerreotype," by Major General Waterhouse, I.S.C.

### PHOTOGRAPHIC CLUB.

OCTOBER 4,—Mr. F. A. Bridge in the chair.

Mr. HENRY W. BENNETT read a paper on

#### ARCHITECTURAL PHOTOGRAPHY.

Speaking to an assembly of competent photographers, Mr. Bennett said he would exclude from his lecture all those common or garden advices generally given to the same class of amateur, and confine himself principally to those matters on which differences of opinion might exist amongst experts. Mr. Bennett first dwelt on the special difficulties encountered by the architectural photographers. The Scylla of limited space on the one hand, and the Charybdis of a too wide-angle lens on the other, being the two principal dangers encountered, which very frequently lead to disaster. The judging of the length of exposure, too, is generally very difficult, and actinometers are of no value, whilst the so-called "intuitive" method of judging the exposure by the appearance of the picture on the ground glass must be altogether discarded. In fact, it is only by experience that one can hope to overcome this difficulty. The best atmospheric conditions will generally be those when light clouds are in the sky, especially when they are low down, as this illumination is best suited to reduce the harsh contrast frequently encountered in this kind of work. As already mentioned, the angle of the lens used is a most important feature, whilst it is generally impossible to work with long-focus lenses; wide-angle lenses frequently give monstrous results. Mr. Bennett found that a seven-and-a-half-inch lens on a whole-plate gave as a rule the best results. It is, however, necessary that the lens cover more than the plate, so as to allow the use of the rising front to its fullest extent. A flat field is, of course, very desirable, and Mr. Bennett is of opinion that the modern anastigmat is in this respect a great improvement on the older lenses. As to the position of the camera, it ought to be about five to six feet from the ground, as a higher elevation might very often be detrimental to the picture. Owing to the long exposures generally necessary, the absolute steadiness of the camera is of great importance, and, in order to secure this, Mr. Bennett recommended a tripod stay, one or two of which are on the market, although they are but seldom bought. In the absence of a proper tripod stay, a large rug will do good service. Mr. Bennett considers the backing of the plate essential. As to development, he invariably begins with what would be generally called a normal developer, and changes the same, as soon as the picture appears, according to requirements. He does not recommend (although this may appear safer at first sight) a diluted developer to begin with, as, in this case, it would be frequently very difficult to build up density afterwards. With regard to printing, very few negatives of this class can be printed without modifications of some sort. Mr. Bennett recommends covering the negative with tracing paper; to cut out the highest lights and the deepest shadows with a second layer of tracing paper. He protested against the word "faking" being applied to an operation of this sort, which is indispensable in order to get an harmonious picture. Touching upon the question of pictorial effect generally, Mr. Bennett was glad to notice that there was a growing tendency to consider this point more and more. Pictorial effect is, however, not inconsistent with sharpness throughout; and he protested strongly against that section of the photographic community which found salvation in "out-of-focus" effects. The suggestion of distance is just as important in a picture of this class as in landscape photography, and an otherwise satisfactory photograph might often be spoilt through its absence. There are photographs in the London exhibitions now which show this defect, and this is all the more

regrettable in those cases where it might easily have been avoided, as, for instance, in photographs of church entrances, where the effect could have been obtained by opening the door instead of keeping it shut. Another defect which one frequently meets with (even in photographs that have passed the selection committees of our principal exhibitions) is the want of completeness. To be a success, the picture must be continuous; the principal object must not take too much space, or be only partially shown. Mr. Bennett then further illustrated the chief points of his lecture by the help of several slides.

A hearty vote of thanks was passed to Mr. Bennett for his very interesting and thoroughly practical lecture.

**Croydon Camera Club.**—The regular weekly evening meetings were, as usual, inaugurated on the 4th inst., being the first Wednesday in October, when the PRESIDENT (Mr. Hector Maclean) briefly addressed the members upon various photographic events, and on the work of the Club. In the course of his remarks he strongly deprecated the illustration, by photographs, of certain subjects as shown at the Royal and the Salon Exhibitions, specially distasteful being some so-called sacred studies representing the Crucifixion and the Entombment, which were calculated to grossly offend the feelings of all who revere the Founder of Christianity. Subsequently Mr. Maclean gave a brief demonstration in order to illustrate the working of a new brand of lantern plate which has just been brought out. Although, after the successful introduction of Velox and similar slow bromide papers, lantern-slide making, without needing a yellow or orange light, is what might be well expected, this was the first occasion that such a plate had made a special claim to this convenient simplification of procedure. Mr. Maclean proceeded to expose and develop a lantern plate in the Club room with one of the electric lights full on all the time. The exposure was one inch of magnesium ribbon at sixteen inches from negative, which was a fairly dense but rather quick printing one. Hydroquinone was used, the slide being developed in about one minute. There was no sign of light fog. The lights came out quite clear. The Exhibition arrangements were brought before members, who were reminded that, to ensure entrance to the *Soirée* on the 24th, prompt application for tickets is necessary. Entries for the Exhibition are now pouring in from all parts. Amongst them are prints from a gentleman whose home is the Silver Palace, Constantinople, and whose office is private photographer to the Sultan. His pictures of Turkish life and scenery will, no doubt, attract considerable curiosity.

**West Surrey Photographic Society.**—The opening night of this Society's new season was last Wednesday evening, October 4, at the Railway Tavern, Battersea-rose, when Mr. H. Vivian Hyde gave a lantern show of quite exceptional merit, entitled "Lowestoft and Neighbourhood." The Harbour, with its boats and shipping, was finely illustrated, and thence to the Broads and Norwich gave occasion for any number of beautiful slides, much beyond the usual. Some brilliant cloud effects were combined with landscapes of value, and the many scenes were accompanied with comments by the lecturer, just topographical enough, so that the whole went with briskness, and to the huge satisfaction of the closely packed audience. A few slides were added of general interest. Some reductions of Mr. Hyde's well-known exhibits were, we think, among the slides shown. Altogether the evening was a great success, concluding with a well-deserved vote of thanks. Mr. W. H. Wilsheer was at the lantern.

**Cornish Camera Club.**—At the Annual Meeting of this Club at Penzance, on Monday evening, Mr. W. E. Baily, of Lynwood (the President of the Club) reviewed the advances in photography during the year, and suggested that members should investigate in the coming year the curious fact that, given the same materials and circumstances, one man could get good results, while another man got only unsatisfactory results. Mr. H. Tonkin (the Hon. Secretary) reported that last year twelve meetings were held, eleven provided for by the members, and the other by Mr. Baldwin, of the Paget Prize Plate Company, who gave a demonstration of Gravura paper. Some of the members had shown a great improvement in their work. The Treasurer reported a balance in hand of 9*l.* 16*s.* On the motion of the Mayor of Penzance (Mr. R. Pearce Couch), Mr. Baily was unanimously re-elected President, and, in acknowledging the heartiness of the vote, Mr. Baily said he hoped to be in a position to ask the members to join him in a short time in a demonstration concerning the Edison-Bell invention. If he could get the instrument, he wanted to bring it to Penzance, and he hoped that they would be able to inaugurate an autumn show. Mr. Couch mentioned that he had recently been engaged in photographing groups of the borough charter, dated 1614, the maces and things of that kind, which he thought might be interesting.

**Rotherham Photographic Society.**—October 3, Annual Meeting. Dr. Baldwin (President) occupied the chair.—The report and Treasurer's statement was considered very satisfactory. The balance in hand was 1*l.* 1*l.* 10*d.* The annual Exhibition had resulted in a loss of 1*l.* 3*s.* 3*d.* Officers were elected as under:—President: Dr. F. B. J. Baldwin.—Vice-Presidents: Messrs. E. Isle Hubbard, J. Leadbeater, and W. Rider.—Hon. Treasurer: Mr. A. S. Lyth.—Hon. Secretary: Mr. H. C. Hemmingway. The other members of the Council chosen were:—Messrs. C. E. Parkin (Hon. Assistant Secretary), F. Oldham (Librarian), J. Caseldine (Auditor), W. Firth, and J. C. Cox.

**Edinburgh Photographic Society.**—On Wednesday evening, October 4, the First General Meeting of the Society was held for session 1899-1900, Mr. A. Eddington, F.I.I. (the President) in the chair.—In the course of his opening address the PRESIDENT said: "What I would like to bring particularly before you to-night is a proposal that the Society as a body should undertake a definite work of permanent value. Last year I hinted at something in the direction that I shall now put before you in more definite form, supported by the approval of your Council. There must be many among us who have in their possession characteristic photographs of Edinburgh. Portions of the

city rich in historic association and of great architectural beauty have been swept away within the memory of many of us, and no record of the change has been preserved by any association or corporate body. The proposal that I have to lay before you is that this Society should form a permanent collection of prints and lantern slides illustrative of Edinburgh. In attempting this work we shall be doing something that is of real value to the Society, and that, in time to come, will form a most instructive pictorial record of the changes that take place in the face of one of the most picturesque and romantic cities of the British Empire—let me say, of the world. The subject would give great scope to the individuality of the worker. Pictorial arrangement, architectural design, historic interest, archaeological features would each call for reproduction. In addition, there is the ever-changing aspect of the City's life, and here the worker in figure subjects would find a wealth of good material. A proposal of this kind, to be properly worked out, would require some systematic effort, and I hope that a scheme of operation will shortly be laid before you; but, speaking generally, it would be desirable that each contributor should send a lantern slide and print of the same subject, and it will be essential that the latter should be in a permanent process, either carbon or platinotype. The prints would be received unmounted and properly classified in albums. It is most probable that, to carry out the idea, it may be necessary to form a section of the Society, the members of which would have portions of the city mapped out for them, which they would undertake to pictorially survey. I have been assured by several members to whom I have mentioned the matter that they would readily join the section and undertake the work, and might I ask for volunteers from this meeting? The Secretary will be pleased to receive their names. There is only one other matter which I would like to bring before you, and that relates to the coming Exhibition. The Council decided last night that there should be a small charge for exhibits in all sections instead of as hitherto only in open sections. The fee will only be one shilling for the two pictures, which members are entitled to send to each section, while the charge in the open sections has been reduced to members from one shilling to sixpence per square foot, non-members paying the same charge as hitherto. This, it is hoped, will spread the small financial burden incurred by the Exhibition more equally over the exhibitors, and press unduly on none. It will afford me much pleasure to again give a gold medal for the best picture by an amateur member of the Society, and the essay competition will be continued under the same conditions as last season. I hope the Exhibition, for which many of us are doubtless already working, will eclipse all previous records in variety of subject and excellence of work, and that in every respect the present season will be one of continuous progress to higher things." These remarks were heartily received, and the Chairman, on the motion of Mr. John Anderson, was accorded a hearty vote of thanks. In the course of the evening the medals and certificates gained at the last annual Exhibition were presented. The new medal, which was designed by Mr. Robert Hope, Edinburgh, was highly spoken of. Afterwards, a lecture on "The Optical Lantern as an Educative Medium," illustrated, by A. H. Baird, F.R.P.S., was delivered, a report of which will appear in due course.

#### FORTHCOMING EXHIBITIONS.

1899.

- October 13-Nov. 4 ... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.
- " 13-Nov. 11... Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.
- " 18-24 ..... Croydon Camera Club. Hon. Secretary, W. H. Rogers, 106, Holmesdale-road, South Norwood.
- " 22-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.
- November 15-17 ..... Hackney Photographic Society. W. Selfe, 70, Paragon-road, Hackney, N.E.
- " 20-25 ..... Longton and District Photographic Society. Thomas Mottershead, 43, Stafford-street, Longton, Staffordshire.
- " 27-Dec. 18 American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.
- December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.
- " 11-Jan. 1900 Huddersfield (Invitation). W. A. Beavers, Cloth Hall-street, Huddersfield.
- " 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.
- 1900.
- April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

- \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE R.P.S. EXHIBITION.

To the Editors.

GENTLEMEN,—Mr. Harold Baker, in his letter which you published on September 29, seems to be so angry with everybody that he does not think it necessary to explain to outsiders what it is all about. He appears to have a grievance against the R.P.S., which I assume they will deal with if they think it desirable to do so; but, on the general question of judging and selecting, which has been brought up by Mr. Baker and others, I should like to be allowed to say a few words. It seems to me that some people do not realise the difference between these two operations. If I understand the position rightly, it is this: the R.P.S., having announced that they are ready to receive exhibits, appoint a Committee of their number to select a sufficient number to form an exhibition. When the pictures are hung on the walls of the Gallery, the Judges, who have been chosen by the members, are invited to award medals for those exhibits which they consider deserving. The Judges' responsibility does not therefore extend beyond the pictures which are submitted to them, and why they should be angry because they are not called upon to go through the laborious task of examining every exhibit sent in I cannot imagine, and, indeed, I venture to think Mr. Baker is not speaking for the majority of the Judges, but is simply expressing his own views. If, on the other hand, his contention is that the Committee appointed by the Council are not competent to make a selection, or are likely to be influenced by unfair considerations, then, I should say, neither are they fit in that case to sit on the Council of the R.P.S., and yet the members showed their confidence in them by placing them there.

The whole question of medalling seems to me to call for reconsideration. I think it is very objectionable, and prevents much good work being sent in, because the authors of it do not wish to put in competition with others. I should like to see it banished altogether, for it seems to me to lower the tone of the Exhibition altogether.

Do you think artists in oil paintings would send their work to the Royal Academy or other large exhibitions if medals were given for the best work?

As a matter of fact, it is quite impossible to decide which is the best picture. Look at the medalling this year at the R.P.S., without reflecting in the least on the Judges' decisions, is it not easy to find many pictures unmedalled which are quite as good, if not better, than some of those which have received awards? I say, therefore, Abolish the system of medalling altogether, and with it will go most of the troubles which exhibitions invariably give rise to.

Mr. Baker seems to have no sufficient reason for resigning the membership of the Society; if there is anything wrong in the system of the Exhibitions, it surely would be better for him to stay and help to improve it. I hope his vexation does not arise from any other cause. I notice there are some of his pictures in the Exhibition; is it possible that he sent some which have not been hung? I suppose only the Seating Committee could answer this question.—I am, yours, &c.,

October 4, 1899.

NEMO.

### TONING BROMIDE PRINTS.

To the Editors.

GENTLEMEN,—Having from time to time noticed some of your readers ask you for a method of toning bromide prints, thinking it might help them to gain their desired end, enclosed is a process which will give all that they may desire. I have tried myself the Velox process. It does not answer with me, and I believe it can only be done by toning after fixing (of course my knowledge is very limited). Trusting you will think it worth telling to others.—I am, yours, &c.,

T. KING.

High-street, East Malling, Maidstone, October 9, 1899.

The tone or colour of the deposit depends on the accuracy of exposure and the developer employed. Every one has their own way of working, various though they are. Bromide paper is one of the most permanent of all the silver papers. To gain that end, thorough fixing must be studied. I always fix in a four ounce in twenty of water for fifteen minutes, washed for a few minutes, and followed by a three ounce in twenty of water for another ten minutes. The toning methods for bromide prints are not very many. Brownish-black prints are much improved by toning in a bath composed of—

#### No. 1.

Sulphocyanide of ammonium .....	20 grains.
Water .....	1 ounce.

#### No. 2.

Chloride of gold .....	2 grains.
Water .....	1 ounce.

Add No. 2 to No. 1, slowly moving the solution all the time, flow over the fixed, washed, prints till the right density is reached. Prolonged toning will give a deep blue tint. Prints must be kept moving all the time. Brown, reddish-brown, and red tones are got by using the following bath:—

#### No. 1.

Ferricyanide of potassium .....	20 grains.
Water .....	20 ounces.
Glacial acetic acid .....	1 ounce.

#### No. 2.

Uranium nitrate .....	20 grains.
Water .....	1 ounce.

When No. 1 is dissolved, add No. 2. This bath must be used at once. It will not keep mixed together. Immerse prints, and keep moving all the time till the desired colour is produced. After toning, wash prints for an hour in several changes of water, acidulated with acetic acid one drachm in thirty ounces of water. If, after half an hour's washing, the whites are at all thick or yellow, immerse in the following bath till cleared:—

Sulphocyanide of ammonium .....	20 grains.
Water .....	10 ounces.

After clearing, continue washing for half an hour in clear water. Prints toned by this process must be thoroughly washed free from all hypo.

### THE RIGHT TO THE NEGATIVE.

To the Editors.

GENTLEMEN,—I should be glad if you would kindly give me a little information on the following matter:—

I photographed some bottles and labels for a firm of spirit merchants, charging them 2s. each for the first print, and 7s. per dozen for further copies, cabinet size.

Shortly after the account was sent in, they demanded the negatives, which I declined to give up, as no agreement was made to that effect, and no mention made of negatives at the time I gave the quotation; they thereupon refused to pay my account, so I have entered the matter in the County Court, and should now like to know of some previous law cases in which it has been decided that the negative is the property of the photographer in the absence of any specific agreement to the contrary.

I have been a regular subscriber to your JOURNAL for many years and have most of the copies by me, but not arranged in such order that I could refer to them very readily. As the case comes on for hearing on the 17th inst., I should esteem it a great favour if you would give me particulars of cases, either in your next issue.—I am, yours, &c.,

A. H. PUGH.

[This matter has been decided many times, and always in favour of the photographer—the negatives are his property. See page 114 of our volume for 1895, also page 194 for 1896. If we had received the letter earlier than we did, we should have looked up other cases. But really there is no question at all in the matter.—Eds.]

### ACETYLENE.

To the Editors.

GENTLEMEN,—Your article upon acetylene in last issue is, we are sure unintentionally, calculated to do harm to this new industry, and we crave your favour to supplement it by further information. The fire insurance offices do not "continue to throw in the way of would-be users difficulties of a harassing and obstructive character." On the other hand, many of the offices have taken great trouble to make themselves acquainted with the characteristics of and conditions surrounding carbide and acetylene; and, speaking generally, their regulations are only such as to protect themselves from careless or ignorant persons. One office has gone so far as to issue a notice that they do not charge an increased premium when acetylene is used.

The remark that impurities are liable to produce explosive compounds when in contact with metal, or to initiate spontaneous combustion, is a relic of the early days when the gas was not properly understood. Such ideas have long been swept away by practical experience.

Mention is made of several foreigners who have experimented with methods of purification, but, as Englishmen, we cannot help remarking that in 1897 we patented a purifier with a special mixture, which has been extensively used ever since, and has never failed to satisfactorily remove the unpleasant smoky fumes which render the use of the gas in closed rooms unbearable without purification.

The grave source of danger said to result from the after-formation of gas in the generators, when the carbide has been removed, is only present in machines of unscientific construction, or self-contained generator lamps, such as are used for bicycles, &c.—We are, yours, &c.,

Westminster, S.W.

THORN & HODDLE.

## THE ECLIPSE PHOTOGRAPH AT THE R.P.S. EXHIBITION.

To the Editors.

GENTLEMEN,—In the Exhibition of the Royal Photographic Society there is a picture, No. 357, which purports to represent an eclipse of the sun as seen at Quetta, on January 28, 1898. It is a very fine picture of clouds, but I am at a loss to understand how it can have been put forward as being like an eclipse of the sun.

High in the sky there appears a bright disc partly hiding a dark one, and surrounded by a bright halo. Now we all know that a solar eclipse is caused by the moon passing between us and the sun; inasmuch as the moon shines by the light it receives from the sun and reflects to us, it is manifest that on these occasions the disc of the moon must be dark, and that the appearance must be of a dark substance, with a convex dark edge obscuring part of the solar disc. This appearance is precisely reversed; it is as though the bright sun were passing in front of the dark surface of the moon. How the photograph was made I do not attempt to say, but I am quite certain it does not represent any phase of a solar eclipse, either at Quetta or elsewhere.—I am, yours, &c.,

J. F. TENNANT, Lieut.-General, R.E.

11, Clifton Gardens, Maida Hill, W., October 7, 1899.

[We have carefully examined the exhibit referred to by General Tennant, and can confirm the accuracy of his description.—Eds.]

## CLAMBAKE.

To the Editors.

GENTLEMEN,—Re your request (September 8), herewith you will find full and complete instructions to prepare a clambake, illustrated by a diagram, so that you can prepare one in England—if (?) you have the necessary articles.

I will make you an offer that, if you will come to New York City at any time in the spring or summer season, I will demonstrate to your inner man how good a clambake is. Please bear this in mind.—I am, yours, &c.,

C. H. CROSSBY.

87 and 89, Washington-street, Chicago, Ill., September 21, 1899.

[We are very much obliged to our friend for the clambake recipe which is given with an amplitude of detail and wealth of illustration that would do credit to a cookery book. Possibly a clambake may one day figure in the programme of a British Convention, and we will treasure the recipe against the appearance of such a contingency.—Eds.]

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

G. H. SHORT (Capetown).—The suggested article shall appear shortly.

RECEIVED.—T. RECKFORD; H. HALL; BUSINESS. These and others in our next.

ARTIGNE PAPER.—ARTISTIC inquires where the Artigne paper, with directions for use, is to be obtained in this country, and its price.—We believe it is sold by Messrs. Adams & Co., Charing Cross-road; also by Messrs. Gaumont & Co., 25, Cecil-court, Charing Cross-road.

Z. W. S. writes: "With reference to inquiry in your last issue by 'J. R. R.' for Braun's lantern slides, I may mention that I obtained a number of the slides in question through Messrs. W. Watson & Sons, 313, High Holborn, and I believe they have still some stock of same."

INQUIRER (Norwich).—An approximate estimate, derived from our experiences of artificial-light photography, would be from 4000 to 6000 c. p.; but no reliable data on the subject are available, much, of course, depending upon the rapidity of plate, whether the subject be light or dark, and so on. However, the power required would be thousands.

AUTUMN PICTURES.—R. BAIN writes: "Referring to the pictures by the late Mr. Vernon Heath, alluded to a few weeks ago, taken in the autumn, and many of which I am familiar with, can you tell me if he used orthochromatic plates and a colour screen?"—No, he did not. Most of the late Mr. Heath's pictures were taken by the wet collodion process.

BOOKS ON PHOTOGRAPHY.—GUILD says: "I have been asked to give a short paper on 'Photography' at an improvement class, or young people's guild, in connexion with our church. It would not have to be technical at all, so I thought of giving a short history of the discovery and progress of photography, its development, briefly describing the different improvements, &c. Will you tell me the best book or books for my purpose? I want my paper to be interesting and entertaining as well as instructive."—In reply: You will obtain sufficient of the history and development of the subject from Jerome Harrison's *History of Photography* and Werge's *Evolution of Photography*. Any dealer will procure the books for you.

MOUNTING GELATINE PRINTS.—F. E. G. says: "Will you kindly advise me? I want to mount gelatine prints, upon ground glass or opal, to get matt surface, and afterwards to dry mount them to preserve the matt. Can you tell me how this is best done, and what mountant to use? Has it been previously described in the JOURNAL; if so, what date? I have a roller mounting machine."—Thoroughly clean the ground glass, then rub it over with French chalk. Squeegee the prints on that, and, when dry, strip off and mount with stiff starch paste. Or a piece of paper may, while the print is on the glass and still wet, be cemented on its back, but that is scarcely necessary to preserve the matt surface.

CHARGES FOR UNMOUNTED PRINTS.—BILTON says: "I am in the photographic view business (local views of my own taking), and should like to know what you would consider I should charge for 6 x 4 unmounted prints where the purchaser wishes to reproduce the views in a publication dealing with the scenery of the district. (1) In case my name is given at foot of reproduction. (2) When it is not so given. I retail the views at 8d. each, but think a different charge ought to be made when required for purposes of illustration!"—1. The minimum charge by the members of the Copyright Union is 10s. 6d. a subject for one edition. 2. That is quite a matter of arrangement between the owner of the copyright and the publisher.

NEGATIVE REFUSING TO FIX.—AJAX says: "I send a negative, which quite refuses to 'fix.' Another negative developed with the same developer, and placed in the same dish of hypo, fixed perfectly in the usual time. I have never known such a thing occur before. Can you tell me the probable cause of it? What the dark stains at the back of the negative are caused by, I do not know. The development was somewhat prolonged. I have tried to fix with cyanide of potassium, but it has no effect!"—This query, with a sight of the negative, caused us some little surprise, inasmuch as the negative is perfectly fixed. Not so, however, the unexposed plate firmly adherent to its back, the film of which the fixing solution could not get at. Indeed, the negative was a very good one till broken by our penknife in separating the two plates. The stains were, on the second plate, caused by the developer getting between the plates.

MOUNTING STEREO PRINTS.—W. WALKER says: "Will you kindly tell me the best way to print stereo pictures on one piece of paper without the trouble of transposing, the same as those you buy commercially? I have tried cutting the negative in half, but find a difficulty in holding the same while printing. Could the negative (the two halves) be cemented on to a plain piece of glass? If so, what would be the best cement to use?"—Put the two halves of the negative together on another and slightly larger plate of glass, and secure them by the edges with strips of gum paper. There is another way, however, without cutting the negative. Take a piece of sensitive paper double the length of the negative, then fold one-fourth of it at each end backwards; this will give a length of the negative, but with double paper. Print on one side and then the other, and cut in half; this will give two prints the right way about.

ENAMELLING PHOTOGRAPHS.—W. S. GRAY writes: "Would you kindly inform me the process of enamelling silver prints as it is done by trade enamellers? I imagine they use collodion; if so, that would be an expensive item, and considerable skill required to obtain an even coating in the case of large prints. Do you think it worth while doing one's own enamelling, or would it be better to continue sending it to a professional trade enameller?"—The method of enamelling prints with collodion has been described in detail over and over again in the JOURNAL and in the ALMANAC. Briefly, it is this: A cleaned glass plate is treated with wax or French chalk, then coated with collodion. The plate, after the solvents are washed away, is immersed, together with the print, in a solution of gelatine, and the two squeegeed in contact. There is no great skill required, after a little practice, in coating the plates with the collodion up to, say, 24 x 18 or larger. As to the question of doing the work at home, or putting it out to be done, this depends upon the quantity to be done, and whether it is worth our correspondent's while to learn to do it for himself.

THREE-COLOUR PRINTING.—TRICOLOUR says: "A customer of mine requires a large number of three-colour prints. I shall be obliged, therefore, if you will answer the following queries, or, if too long for that, by saying what is the best I can do in the matter. My understanding of the matter is to the effect that I must secure three negatives taken with three different screens, so as to have one for each of the primary colours. The next stage I understand to be three process blocks, one each, as before, to be printed from in the usual way, so as to superimpose the relative colours, and thereby give the desired effect as representing in natural colours the object photographed. Please say in reply if the foregoing is correct, and, if not, point out error; also whether or not the work of printing can be as successfully done by lithography. If you can put me on the right track to either do the work myself, or, when the negatives are taken, to get the prints worked off, I shall be greatly helped. I have previously done the work by blocks and printer's aid, but only in two tints; now it must be three, and I realise the importance of your often-quoted advice that the professional photographer should get such work. I may add that, consistent with good work, the price must be as low as possible. As I have said, a reply that will set me going will be of service."—In reply: Our correspondent correctly outlines the three-colour half-tone process, but we cannot recommend him to undertake production of the blocks and the prints in colours unless he perceives a return for the considerable sum of money which the necessary installation would cost. Our advice is, having obtained the negatives, to get estimates for the colour-printing from such firms as Messrs. Waterlow, Finsbury; Messrs. Swain, Barnet; the Arthur Cox Company, Birmingham; and other firms who undertake the production of work in three colours.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE thirty-ninth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1 next. Its preparation is already receiving attention. This year's ALMANAC reached a total of 1508 pages, and the entire edition of 20,500 copies was sold out within about three months of publication. Of no other photographic book ever issued can two such unique facts be recorded.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which that publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1900. At the same time we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1900 will appeal to photographers all the

world over as a daily reference guide in practical work. The formulæ will be revised where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Adhering to an old and much-appreciated custom, we invite short contributions on practical subjects for the pages of the 1900 ALMANAC. Those of our friends intending to co-operate with us in in this respect will oblige us by letting us have their MS., sketches, &c., at the earliest possible date.

Secretaries of societies will also oblige if they will forward us lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, &c. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, &c. Those firms who wish to take advantage of this feature should communicate with us as early as possible.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

## EX CATHEDRÂ.

A FORTNIGHT ago we drew attention to the fact that our contemporary the *Stage* was supplying its readers with bromide enlargements of their portraits at cheap rates, and we congratulated that admirable paper on not following in the path of other newspapers that have worked this somewhat ancient scheme in saying that enlarged pictures which can be produced for a very few shillings each are charged for by photographers at the rate of four or five guineas. By the last number of our contemporary we perceive that we were somewhat premature in our congratulations, for the enlargements are said to "bear comparison with those for which four or five guineas are usually charged." We have examined some of these enlargements, and can only say that the photographer who obtained four or five guineas for them would be an exceedingly clever and fortunate man. Between these productions and those upon which an amount of hand work is bestowed which

justifies a charge of four or five guineas there is as much difference as there is between chalk and cheese. The *Stage* enlargements are not worth a penny more than what is charged for them, viz., 12s. 6d., and no inconsiderable harm is done to professional photographers by the suggestion that the latter obtain four or five guineas for such productions. Our contemporary so well and jealously guards the interests of its own great *clientèle* that we must suppose it is by pure inadvertence it is harming professional photography in the way we have indicated.

\* \* \*

THE professional photographers of the United States of America are being strongly urged to unite for purposes of mutual help and interest. At the recent National Convention a committee of professional men was appointed to draw up an address to their brethren, and the extracts we here give from that document will show the objects held in view by those who are advocating union and combination. The Committee say that, "in view of the fact that the spirit of the age is organization, and that almost every industrial institution in the United States is forming itself into an adhesive organization with a common centre, with power to wield the body as a whole for defensive purposes, the time is ripe for photography (a business which to-day is indispensable) to follow suit. When you come to consider it in detail, you are confronted with conditions probably not to be found in any other vocation, one of which is the plan upon which the business part of photography has always been conducted—that of the 'survival of the fittest.' This has cut the profits down on business as a whole to such a pittance that it makes honest endeavour meet with probably less remuneration than any other business of the same magnitude; also it has created a less degree of professional courtesy than is to be found in common vocations."

\* \* \*

DIMINISHING prices and profits are obviously the main argument in favour of the suggested combination. We may get some idea of the proposed remedies for the "cutting" of prices which it is sought to introduce by a perusal of a further portion of the manifesto: "We beg you to discuss the matter thoroughly, and to appoint a committee of your very best business photographers to meet a like committee from each State, in Milwaukee, the day before the National Convention convenes in 1900. In the mean time let every photographer give the matter earnest study, and let the committee, as far as possible, find out what is the consensus of opinion and submit the same to the General Committee at Milwaukee. It is suggested by some to have a copyrighted stamp or seal for its members to use on all photographs, and, as the organization grows in strength, to have a standard of proficiency for every applicant for membership; also a Board of Arbitrators to settle 'picture wars' between its members and do all it can in the way of getting all other organizations (labour unions, &c.) not to patronise a non-union man. By others it is recommended to try to get the manufacturers to agree not to furnish material to any one who refuses to hold the price to a certain standard after the arbitrators (who are appointed respectively by the union, the manufacturers, and the parties themselves) have failed to agree." This document is a little vague in parts, and some of its suggestions are clearly impracticable, but the underlying intentions are unquestionably good. We shall watch the course of the proposed experiment with the greatest interest. The machinery of the National Convention

should be a valuable aid in promoting union amongst United States professionals for the purpose of preventing price-cutting and raising the standard of work, and, if it is successful in the first of these objects, it will deserve well of its members and supporters.

\* \* \*

THE many photographers, and particularly those who make a practice of attending the annual conventions, who know Major J. D. Lysaght, will learn with interest that the gallant officer is one of those who sail for the Cape by the *Roslin Castle*, leaving Southampton to-day (Friday, the 20th). This ship takes the first drafts of the Army Corps. So many of us have for years past been accustomed to speak of Major Lysaght as Major Lysaght that it will not seem easy to call him Colonel. But Lieut.-Colonel he now is, and we are sure that we echo a general feeling in expressing a hope that we shall have many future opportunities of calling him Colonel instead of Major. And this means, of course, that we all wish him safely back from the task of chastising his brother "Boer," with a long photographic life in front of him.

\* \* \*

AMONGST those who sailed for South Africa last week was Mr. W. K. L. Dickson, the chief technician of the British Mutoscope Company, who, with his assistants, proposes taking animated photographs in connexion with the hostilities between the Boers and Britons, always assuming, of course, that the proper opportunities present themselves. "Actual events in connexion with the war" are promised, and Messrs. Donald Currie & Co., of the Castle line of steamships, have made arrangements to facilitate in every possible way the return of the photographic films to this country. Imagine what crowds would be attracted to the Palace Theatre of Varieties if the biograph showed a photographic representation of another battle of Majuba Hill—with the defeat of our "brother Boers!"

\* \* \*

WE trust that the sentences of two and three months hard labour passed last week at the London County Sessions on two youths for exhibiting in a public thoroughfare cinematographic pictures of an improper character will act as a warning to the many persons at seaside resorts and other places who have been utilising that adaptation of the cinematograph principle, the mutoscope, for placing on view moving photographs of a risky or suggestive character. This matter has engaged widespread attention for many months past, and the Press, headed by the *London Times*, has published numerous indignant protests against the harm to the morals of the community which these degrading exhibitions must surely work. Not the least regrettable part of the matter was the indifference on the part of local authorities to what was going on immediately under their eyes; but, now that the London justices have dealt out sharp punishment to a couple of offenders brought before them, we may hope that discouragement of an equally emphatic kind will be given in all parts of the country to the prostitution of a beautiful and interesting branch of photography to the base motives of viciously minded showmen.

\* \* \*

MR. R. B. LODGE, of Enfield, has justly gained world-wide credit for his photographs of wild birds in a state of nature, with their nests, eggs, and young; and four years ago his work was singled out for the honour of the Royal Photographic

Society's medal. We have just had the pleasure, for the first time, of examining a series of prints from Mr. Lodge's negatives (which number some hundreds), and must heartily congratulate that gentleman on the patience and skill he has displayed in getting photographs of these shy and elusive sitters. We are conscious, in looking at these tele-photographically produced pictures, that we are beholding the natural life of the feathered world on the rocks, amongst the reeds, in the trees and the bushes. We can conceive of no more effective and convincing aid to the study of this branch of natural history than a set of Mr. Lodge's eminently realistic photographs. A full and priced list of the prints is obtainable from Mr. J. A. Reid, "Kineraig," Cutcliffe-grove, Bedford, and this gentleman also arranges for Mr. Lodge to give illustrated lantern lectures on the subject of bird life, &c.

\* \* \*

THE fact that when it is winter in Great Britain the summer sun is shining at the Antipodes was never more forcibly impressed upon us than a day or two since, when we were glancing through our contemporary the *Australasian Photographic Review*, and the late autumn mists outside were heralding the approach of the dreaded English winter. Our contemporary has a joyful article headed "Welcome Spring!" It is a poetical review of the balmy Australasian seasons from a photographic standpoint, and the writer is revelling in pleasant anticipations of the first blush of spring and a "grand time." Decidedly our Antipodean *confrère* makes us envious of him. From his interesting pages we learn that the Ives and Joly processes of colour photography have, for the first time, been practically demonstrated in Australasia by Mr. Mark Blow of Sydney. We shall be curious to watch the progress of those processes down under. Beautiful though the results are, they have not, to employ the popular phrase, "caught on here" to anything like the extent they both deserve.

\* \* \*

WE have received the first three numbers of *Photographic Life*, published by the *Photographic Life* Publishing Company, Nepera Park, New York, otherwise the Nepera Chemical Company, manufacturers of Velox, &c. The new paper is edited by Mr. W. E. Woodbury, and, while it gives the reader much information of a practical kind, essays, by means of illustrations, quips and cranks, and jokes, to treat photography from a humorous standpoint. In this respect *Photographic Life* is a somewhat novel departure in the journalism of photography. It is very well produced, and will probably attract many readers.

#### MOUNTANTS AND MOUNTING.

IT may seem almost an act of supererogation to many to devote an article to the above simple subject, yet amongst the most frequent queries we have to reply to in the Answers column are those relating to mountants and mounting. Scarcely a week passes without our being asked by one correspondent or another how to mount photographs without the mounts cockling, or how to mount them on the leaves of an album without the same thing occurring. Now, there is no question that a cockled mount is a very unsightly thing, whether it is framed or unframed; also, that an album with its leaves so buckled that the book will not close flat is very ugly. The avoidance of these evils, without the aid of a

rolling press large enough to take the mounts, is, however, no easy matter to overcome; and even with that aid at command, unless certain precautions are taken in the first instance, it is sometimes difficult.

In the case of the prints having to be mounted in an album, the rolling of the pictures is, of course, out of the question, unless, indeed, the album is first taken to pieces, and that is really the proper course to pursue when the best result is imperative. A bookbinder will, however, take the album to pieces and rebind it, after the prints have been mounted and rolled, for a very small sum, and it is somewhat surprising that this is not more often done than it is. We shall here assume, however, that this cannot be done, and see how the best results are to be secured without it.

In the first place, it will be well to consider what it is that brings about the cockling, so that, when that is fully recognised, the conditions for its avoidance, or at least reducing it to a minimum, will the better be understood. When paper, whether in the form of a print or a mount, is moistened with water, however slightly, it has a tendency to expand, and it contracts again as it dries. Hence, when an aqueous mountant is applied to the back of a print, it expands, and, if much water is present, greatly. If, while in this expanded state it be put upon the mount, it is larger than it was when dry; then, as it dries, it contracts again, and in doing so draws the mount with it, and so produces buckling. This is not all, for the moisture in the print also causes the centre of the mount to expand, and thus further increases the evil.

Now, a little consideration will show that, the drier the print and the mount can be kept during the operation, the less will be the expansion, and, consequently, the less will be the cockling. Conversely, the wetter the print is made the more will the difficulty be increased. Many photographers are in the habit of having their prints mounted wet. Now, it will be obvious that this condition, whatever mountant be used, is fatal in the avoidance of cockling with thin mounts without rolling, because the pictures are put on the mounts in their most expanded condition. Even after rolling they often cannot be made perfectly flat if the mounts are very thin.

After what has been said, it will be seen that, if the print be dry and the mountant contain no water, there would be no cockling. Have we such a mountant? Yes; in a solution of indiarubber in benzole. When that is employed, the pictures and the mounts remain perfectly flat. This mountant unfortunately, however, is not at all satisfactory, as it is found, after a time, that the rubber is liable to perish—becomes resinised—and the picture peels off. Alcoholic solutions of different resins would cause no expansion of the paper, but, in practice, they have not been satisfactory for mounting purposes; therefore we have to rely upon aqueous mountants. There are ways, however, in which these may be utilised in what may be termed almost a dry state.

Some years ago Mr. A. Cowan published a dry method of mounting. It was this: the back of the print was coated with starch paste and allowed to dry; the surface of the mount was then slightly moistened with a damp sponge, and the two passed through a rolling press, when perfect adhesion was secured. Here is another method we saw in use in a large Continental publishing house, where the pictures were issued on plate-paper mounts with India tint and titled. The method was this: the back of the print was coated with a thin solution of gelatine, dried, and then trimmed; the India paper was slightly damped between blotting-paper. Next a copper

plate, with the title engraved upon it, was heated and inked in after the usual manner of copper-plate printing. It was then placed on the bed of the copper-plate press, the print put upon it, then the damp India paper, and on that the plate paper, after its surface had been brushed, as is usual with printing on India paper; the whole was then passed through the press. The damp India paper caused the gelatine to adhere to it, and it adhered to the plate paper by virtue of the brushing it had received. In this way the mounting, titling, and plate-marking are done in a single operation. These mounted prints were as flat as if they were copper-plate prints instead of mounted photographs.

As, however, the above methods are not applicable to mounting photographs in albums, other means must be adopted, and, from what has been said, it will be manifest that the object must be to reduce the water in the mountant to the smallest possible quantity, and, at the same time, to get the print into position on the mount before the paper has time to expand to any great extent: the great thing to be avoided is the expansion of the paper. It will be obvious, for this reason, that if, say, starch paste be used, a thick solution, thinly and quickly applied, will cause less expansion than will a thin solution applied thickly. Starch, however, is not to be recommended for our present purpose, because, however thickly the paste be made, it must necessarily contain a large proportion of water.

In the ALMANAC is a formula for a mountant for photographs that greatly minimises the cockling, but success with it depends largely upon conditions as well as the character of the gelatine employed. We propose to deal with this subject in a future article, and show how photographs may be mounted without any cockling whatever even when thin mounts are used.

**The Flicker Photometer.**—This new "light measure" is so named, not, as might be imagined, after its inventor, but from an ingenious application of the flickering produced by uneven illumination, under certain conditions; yet, in a sense, it is a misnomer, as, when the time for measurements arrives, the flickering has ceased. A description of the apparatus, the invention of Mr. O. N. Rood, whose volume on *Modern Chromatics*, in the "International Series," is a most valuable and useful exposition of the subject, is described in the *American Journal of Science* for last month. The construction is formed on the general idea that two beams of light traverse the axis of the instrument and illuminate the two surfaces of a rectangular prism placed in front of the eye. Between the eye and the prism is placed a cylindrical concave lens, which is made to oscillate quickly, and so bring alternately into view, and in rapid succession, each illuminated surface of the prism. When the illumination is uneven, a certain flicker is perceived; but, when equality is brought about, the flicker ceases. The idea appears simple and ingenious, and might prove to point out a ready means of judging of the relative luminosities of various samples of glass, or other media, for dark-room use—a problem closely connected with that of a safe light. Though many valuable experiments in this direction are on record, there yet remains to be tabulated an exact, easily applied, record of the actinic power in relation to actual intensity of illumination of the many coloured media now available.

**Purity of Bromides.**—The purity of the salts employed in the production of the very groundwork of all modern photography, the bromide of silver, is a matter of paramount importance; for, just as the necessity of purity of ingredients and absence of contamination in the silver bath was of essential importance in the wet-collodion process, so must the conditions governing the precipitation

of the bromide be exact, and free from uncertainty, when uniform results are expected. Some years ago an examination of samples of bromide of potassium, obtained from first-class firms, was made, and a table given showing their various deviations from absolute purity. It was found that by far the larger number of samples were contaminated with bromate of potassium, an impurity which, though readily removable, it is true, if its presence were known, would yet, under certain circumstances, be decidedly objectionable. Quite recently, M. Baubigny read a paper before the Paris Academy of Sciences, in which he pointed out the constant presence of chlorine in bromide of potassium; indeed, he states that the very purest sample he could obtain commercially contained 0.01 per cent of that haloid.

THE method he employed for ascertaining the proportion present, which would naturally be always comparatively small, may be interesting enough to quote. About a quarter of an ounce of the bromide and three-quarters of an ounce of sulphate of copper were dissolved in about five ounces of water, and forty-five grains of permanganate of potassium added. A current of air is passed through to carry off the liberated bromine, and the liquid heated gradually to boiling. In about ten minutes the bromine, as tested by the smell, will be all dissipated. About nine grains more permanganate are added, and the liquid heated until fluoresceine paper no longer reacts when held in the vapour. The liquid must not be reduced by evaporation beyond one-half its bulk. All that is then necessary is to titrate the chlorine in the usual way by precipitation with nitrate of silver.

**Deterioration of Oxalic Acid Solutions.**—We were recently asked if we could account for the imperfect action of a platino-type developing solution, which, though it had never before been used, behaved in a manner quite differently from some freshly mixed solution made in exactly the same proportions. Inquiry elicited the fact that there was a large fungoid growth in the solution, which had been made and put aside for twelve months. Now, it is obvious that something must have been disintegrated to produce the fungus, which was quite sufficient to account for any lack of success; but, beyond this, it is well known that solutions of oxalic acid, more especially if exposed to light, gradually become reduced in strength. Some recent experiments by Herr W. P. Jorisson have been in this direction, and a number of interesting facts brought to light. Thus a sterilised solution kept in the dark for 101 days suffered no loss, but, after exposure to the light for half that time, its strength was appreciably reduced. Admixture of sulphuric and of boric acid could not arrest decomposition in the light. Thus a centinormal solution, which, of course, is much weaker than would be used for photographic purposes, was exposed to light for seventy-eight days, and the acid was entirely decomposed. From these experiments we may draw the moral, that all such solutions intended to be kept for stock should first be sterilised by boiling, and then kept entirely in the dark.

#### GELATINO-CHLORIDE PAPER.

M. A. BLANC described recently, before the National Union of Photographic Societies of France, the following method of preparing gelatino-chloride paper, which, he states, has the property of keeping for some time.

The principal feature of his method he states to be the use of a substance for which the free silver nitrate has a greater preference than that of the fibres of the paper. The formula should be strictly adhered to, or else inferior results may be obtained.

First prepare what he calls his

#### "EMULSION CONSERVATRICE."

Alcohol (90 per cent.).....	15 parts.
Pale shellac (in scale).....	5 "
Dissolve by a gentle heat, and pour all at once into	
Boiling water .....	100 parts.

Then filter through absorbent cotton-wool. The whitish-yellow emulsion formed will keep for a long time.

## PREPARATION OF THE SENSITIVE EMULSION.

## A.

Emulsion gelatine .....	9 parts.
Chloride of cobalt (5 per cent. sol.) .....	6 "
*Neutral tartrate of ammonia.....	2 "
Ammonium citrate .....	0.5 part
Water .....	70 parts.

## B.

Citric acid .....	2.3 parts.
Distilled water .....	20 "

When dissolved, add—

Silver nitrate.....	2.5 parts.
---------------------	------------

Place the vessels containing A and B in a water bath, and the temperature must not exceed 70° or 80°. Add, all at once, B to A, and then add to

Alcohol (90°) .....	10 parts.
Emulsion Conservatrice.....	5 "

Filter through a tuft of absorbent cotton-wool, and it is ready for use.

He further states that the alcohol facilitates the coating of the paper, the silver chloride gives the great sensitiveness, and the tartrate the vigour; the citrate is a restrainer, the citric acid increases the contrast, and helps with the shellac to keep the paper.

## CONCERNING FLUID SCREENS AND THEIR APPLICATION TO ORTHOCHROMATIC PHOTOGRAPHY.

A lecture given on March 31, 1899, before the V. Section of the Imperial Russian Technical Association, St. Petersburg.

[Translated from the *Photographische Correspondenz*.]

In September 1898 a very interesting photographic treatise by Dr. Nagel, lecturer for the Chair of Physiology at Freiburg-<sup>i</sup>/B., was published in the *Biologisches Centralblatt*, the subject being "Concerning Fluid Colour Screens."

A colour screen is understood to be any transparent coloured medium which has the power to decompose a pencil of mixed white light. One portion of the rays is cut off by the colour filter and the other portion is transmitted. Filters of this kind have been used in photography for a considerable time. Red and yellow glass being absorbers of the chemically active light rays enable the photographer to illuminate his dark room so that he can carry out complicated manipulations with light sensitive substances without their being affected. The discovery of orthochromatic, photographic plates, sensitive to those rays which had been regarded as chemically inactive (non-actinic)—the red, the yellow, and the green—brought about a further extension of the use of colour filters. A want was soon felt for screens that transmitted monochromatic light only, that is to say, rays of a particular colour. In most cases it is no easy task to secure monochromatic rays by decomposing light with a prism, and special difficulties arise in the application of the process, if it is required to illuminate a comparatively large surface with monochromatic light. For the same reason, biologists were also compelled to use light filters. The study of various biological processes of the animal and vegetable kingdoms under the influence of monochromatic light has occupied men of science for some considerable time. By means of such investigations botanists have been able to prove that the formation of starch in the leaves of plants, by the carbonic acid in the air, takes place with greatest activity under the influence of red and yellow rays. The most convenient light filters would be coloured glass, but a pure spectrum colour is only obtainable with deep ruby. Other kinds usually transmit various rays of light, thus giving complicated absorption spectra when examined with the spectroscope. For instance, various kinds of glass which I have examined transmit the following rays:—

Pale ruby glass: red and orange rays (to wave-length 595.5); yellow glass: red, orange, yellow, and green (to wave-length 492); green glass: some orange, yellow, and green (that part of the spectrum between wave-lengths 598.8 and 488.5).

Moreover, as Dr. Nagel has correctly remarked, we seldom find glass of quite even colour. As for gelatine screens, they are quite irregular in colour and not perfectly transparent. They also deteriorate easily under the influence of heat and moisture, and, being stained with aniline dyes, are not permanent, and fade when exposed to sunlight. Among the more perfect light filters, those which contain coloured solutions in glass

\* This may be replaced by the same quantity of Rochelle salts.

receptacles with parallel sides must be included. They are very transparent, perfectly uniform, and transmit much more light than coloured glass or gelatine plates.

Cells for coloured fluids are now made by various opticians. The State Securities Department (St. Petersburg) has four of these made by Zeiss of Jena. But they may be easily extemporised. According to N. Laehtin, they may be made of two squares of thin plate glass separated by strips of thick, flat plate glass of suitable length placed round three of the sides. They may be cemented together with a composition of five parts of resin and two parts of yellow wax. Alkaline solutions must not be used in these cells, as they would form an emulsion with the resin and soon render the cells useless. As the coloured fluids are generally used in 1 c. layers, the parallel walls of the glass cells should be that distance apart. If we now turn to the various coloured fluids, we shall also find that they give very complicated absorption spectra. In the years 1893 and 1894 Hruza and Hazura published a table of such spectra in their work upon "Light Filters and Sensitisers (Strahlenfilter und Sensibilisatoren). These authors examined a very large number of organic dyes and mineral salts. It was found that only few red colours, such as palatine red, A (page 7), tuch red, G, extra (page 10), diamine-scarlet (page 15), and safranin P (page 39); transmitted monochromatic light, even if in very concentrated solutions and in layers 1 c. thick. Solutions of other colours give more or less complicated spectra. I will only instance a few. Amongst yellow dyes, picric acid transmits red, orange, yellow, and green rays; aurantia, red, orange, yellow, and some green rays; chromate of potash, some red, orange, yellow, and green. The green solutions of methyl green and malachite green transmit red, green, and blue rays; sulphate and nitrate of nickel, orange, yellow, green, and blue rays; and chloride of copper, yellow, green, and part of the blue rays. The blue solution of cyanine transmits red, blue, and violet rays, sulphate of copper solution, a small part of the orange and the yellow, green, blue, and violet rays. The violet solutions, methyl violet, ethyl violet, crystal violet, and permanganate of potash transmit part of the orange and the blue and violet rays.

Dr. Nagel found that, if several different pigments are simultaneously dissolved in water, solutions are obtained which transmit monochromatic rays (more or less); but he did not give any details as to weight, as he combined the colours with the aid of the spectroscop, which is much more convenient than making up the quantities by weight. He recommends a solution of lithion carmine as a filter for red rays. Lithion carmine is prepared by dissolving 2.5 grammes of carmine in 100 c. c. of a saturated solution of carbonate of lithium. By diluting this saturated solution with water a fluid is obtained which transmits the red part of the spectrum as far as line, c. In this condition the fluid is rather dark, but it must not be forgotten that the greater part of the light is absorbed and that the transmitted portion of the spectrum is consequently very small. We must also bear this fact in mind in connexion with other colour filters, and especially the yellow, through which only a very small band of the spectrum is transmitted. By further diluting the solution of lithion carmine we obtain, according to Dr. Nagel, a fluid which transmits the red and orange of the spectrum as far as line, d. It is considerably more luminous than ordinary ruby glass, and gives the same absorption spectrum. It is true that lithion carmine diluted to this extent transmits not only red and orange, but also a small portion of the blue rays, but the latter can scarcely be detected with the spectroscop. Hruza and Hazura also noticed this, and included blue in the spectrum of a very dilute solution of carmine. As proof of the transmission of the blue rays through a solution of lithion carmine, I would mention the following facts. It is well known that the blue rays are much more actinic than any other. Many light sensitive substances are apparently only reduced under the influence of blue and violet rays. The emulsion used for ordinary photographic plates belongs to this category. I ascertained the sensitiveness of ordinary Ilford plates by means of the scale of a Warnerke sensitometer, firstly for the rays transmitted by a dilute solution of lithion carmine (with absorption spectrum as far as the rays of wave-length 593.4), and, secondly, to rays transmitted by lithion-carmine and a concentrated solution of picric acid, which latter, it is well known, absorbs the blue and violet portion of the spectrum. The results obtained differed widely from each other.

In the first case ordinary plates (yellow label) exposed for two minutes gave No. 17 W. after development. In the second case, after twenty minutes' exposure, it was impossible to develop any number at all. Ilford isochromatic plates gave No. 17 in the first case after six minutes' exposure, and in the second case after twelve minutes' exposure. I also exposed some panchromatic plates made by Messrs. Lumière upon Dr. Hübl's colour chart. A negative was made with a lithion-carmine filter,

and another with lithion carmine and picric acid. The difference between them is very marked.

I may here mention a very good method, by which to ascertain if an orange-red screen transmits blue rays. If it is placed in front of a screen of saturated sulphate of copper solution (1 c. thick), the light transmitted by both is either brown-violet, or yellowish-brown. In the first case the screen under examination transmits blue rays, as may be seen with lithion carmine, erythrosine, and saffranin. In the second case the blue rays are cut off as with a solution of mandarin, to which I shall refer presently.

Dr. Nagel obtained a coloured screen, transmitting only the orange part of the spectrum between the Fraunhofer lines C and D, by dissolving saffranin and acetate of copper in water. He added to a concentrated solution of acetate of copper, which absorbs the red rays, a few drops of acetic acid, and then added drop by drop a concentrated solution of saffranin, until the violet, blue, green, and yellow rays were also absorbed. In this way a solution is obtained which transmits only that portion of the spectrum lying approximately between wave-lengths 640-600 (661.4-601.1).

**Yellow light filters.**—To a saturated acid solution of acetate of copper, which absorbs the red and part of the orange rays, add drop by drop a saturated solution "orange G" acidified with acetic acid, which absorbs the violet, blue and most of the green rays. A brown fluid is thus obtained which transmits a small band of orange, the yellow and a small part of the green rays, or that portion of the spectrum from 620-570 (610.9-569.4).

A greenish-yellow filter may be obtained, according to Dr. Nagel, by combining solutions of acetate of copper and bichromate of potash, or picric acid. If crystals of acetate of copper are boiled in an excess of saturated solution of bichromate of potash acidified with acetic acid, a green solution is obtained which transmits that portion of the spectrum between 580  $\mu\mu$  and 530  $\mu\mu$ . (I obtained in this manner a solution which transmitted the rays between wave-lengths, 602.2-540.1). If picric acid is substituted for bichromate of potash, the solution transmits that part of the spectrum between wave-lengths 580-520 (according to my experiments between wave-lengths 608.2-499.7).

A green light filter may be obtained by combining a saturated solution of chromate of potash with a saturated solution of ammonio-oxide of copper. The latter is added to the solution of chromate drop by drop until all the red, orange, yellow, and greenish-yellow rays are absorbed. The portion of the spectrum transmitted by this solution lies between wave-lengths 535-495  $\mu\mu$  (according to my experiments between wave-lengths 555-508.0  $\mu\mu$ ). For absorption of the blue-green rays Dr. Nagel adds to the solution a few drops of an alkaline solution of fluoresceine.

The blue part of the spectrum is transmitted by a weak solution of methyl green, but at the same time the extreme part of the red is also transmitted. The latter may be cut off by acetate of copper. To prepare such a filter, add to a solution of acetate of copper a concentrated solution of methyl green, drop by drop. The transmitted portion of the spectrum ranges from about 500-460. By placing in front of this screen another cell containing a weak solution of permanganate of potash, which absorbs the blue-green rays from 582.2-468.2, the part of the spectrum transmitted may be reduced to 486-460  $\mu\mu$ . If we add to the blue solution a solution of gentian violet, drop by drop, we can isolate that portion of the spectrum from 460-430  $\mu\mu$ .

The violet part of the spectrum (from 470-410  $\mu\mu$ ) may be obtained by using two solutions: ammonio-oxide of copper (1 part of saturated solution to 7 parts of water transmits the rays as far as wave-length 541) and a solution of permanganate of potash. As these solutions should not be mixed, they must be used in a double cell. The following table by Dr. Nagel gives the spectra of the light filters we have mentioned.

Dr. Nagel examined his light screens by means of an incandescent burner. As I followed the recipes given in his work, I also used the same source of light. I should add that Dr. Nagel describes very fully and completely how the light filters may be prepared, but I cannot agree with him that their preparation is very easy and simple. As an instance, I may mention the preparation of the green light filters.

Adding the saturated solution of ammonio-oxide of copper drop by drop to the saturated solution of chromate of potash is a very tedious operation, quite apart from the circumstance that more of the cupric solution may be added than is requisite. Moreover, the second solution is diluted in unequal proportions by addition of larger or smaller quantities of the first solution, and its original standard of absorption is thus subject to irregular variation. Lastly, a turbid deposit is formed when some of the solutions are mixed, and this must be removed by filtration. It is therefore very difficult to prepare two light filters which give iden-

tically the same absorption spectrum. Monochromatic filters may be prepared much more easily in another way which I have used for some years.

In 1894 the following problem was given me. A specialist offered the State Securities Department a new process for preventing forgery of credit notes. His proposal was to print the design, ornament, writing and protective network in different coloured inks, each having the same effect upon a photographic plate. In this way, by use of photographic processes, it would be impossible to obtain the design of the protective network without, at the same time, including the writing and ornament. It was required to find some method by which the various colours could be separated by photographic means. If the colours could not be differentiated, the process which was offered would be of great value in the printing of credit notes. However, by use of the colour filters I have mentioned and various kinds of orthochromatic plates, I succeeded in photographing the colours separately. By comparing the absorption spectra of various coloured fluids I found that, by combining them in layers 1 c. thick, I could ultimately isolate any portion of the spectrum. For instance, if we take a solution of mandarin G extra, Orange II,\* in proportion of 1 part of saturated solution to 1 part of water, so that only the red and orange rays (to wave-length 590.2 of the spectrum) are transmitted, and, if we also take a solution of sulphate of copper, 1 part of aqueous saturated solution to 4 parts of water, which transmits orange, yellow, green, blue, and violet (that part of the spectrum as far as wave-length 654.6  $\mu\mu$ ), and, if we fill each division of a double cell with one of these fluids, then only the orange rays can pass through the combined filter, for the red rays are cut off by the solution of copper, and the yellow, green, blue, and violet by the solution of mandarin. The requisite strength of the solutions can be determined with sufficient exactitude by means of the spectroscopes. If we take a still more dilute solution of mandarin (1 part of saturated solution to 3 of water) so that

\* This dye (in solution of 1 in 1000) has been used since 1895 by Herr W. Weissenberger as a filter for making the blue negative in three-colour work.

the red, orange, and yellow rays (to wave-length,  $579.3 \mu\mu$ ) are transmitted, and likewise a saturated solution of chloride of copper, which transmits yellow, green, and part of the blue rays (region of the spectrum from wave-length  $589.4$ – $469.6$ ) we have a combination of solutions which transmits pure yellow light. The same solution of mandarin (1 part to 3 of water) combined with a saturated solution of sulphate of copper (which transmits that part of the spectrum to wave-length  $618.8 \mu\mu$ ) gives a small band of the spectrum comprising the yellow and a small portion of the orange rays. Pure green rays are isolated by combining a solution of ammonio-oxide of copper (1 part of saturated solution of copper sulphate, 15 parts water, 1 part ammonia 0.91) with a solution of bichromate of potash (1 part of saturated solution to 10 parts of water), or saturated aqueous solutions of chromate of potash or picric acid may be substituted. I combine the solutions by means of a double cell formed of three plates of glass, the middle of which divides the enclosed space in two sections. In this way the two solutions in the separate divisions do not mix with each other. It is true that by combining the solutions in this manner another reflecting surface is introduced which entails some loss of light, but the diminution is comparatively small. I commend the following table of absorption spectra to the notice of photographers:—

WAVE-LENGTHS ACCORDING TO ÅNGSTRÖM.

I will now proceed to the application of these light filters to photographic purposes.

It would be particularly interesting to ascertain the sensitiveness of various kinds of orthochromatic plates for the pure colours of the spectrum by means of some kind of sensitometer. It is only by such means that we can arrive at a quantitative expression of the capacity of various sensitizers to increase the sensitiveness of photographic plates for the various rays. In such a manner only can we ascertain the exact difference between two sensitizers of similar character, as, for instance, eosine and erythrosine. Moreover, as soon as we can ascertain definitely for which rays the plates in question are least sensitive, we can illuminate our dark room with that kind of light. For this purpose I have constructed a lantern, the front of which is made of a double glass cell consisting of three parallel glass plates. The two divisions may be filled with any suitable coloured fluids to isolate any particular kind of monochromatic light. Unfortunately, I have not yet had sufficient spare time to make an exhaustive series of experiments. For this purpose it would

be necessary, by means of a constant source of light, to measure photo-metrically the quantity of light transmitted by each colour filter, and thus ascertain the most suitable type of sensitometer for the series of experiments. I have only made a few experiments in this direction, but they may be of interest to the practical photographer. I selected for my experiments three colour filters of approximately the same intensity, namely, a saturated solution of picric acid; as green-yellow filter, a combination of the solutions of acetate of copper and picric acid; and, as red-orange filter, a combination of lithion-carmin solution and picric acid solution (it would be more convenient to use solutions of mandarin of suitable strength). The first, a pale yellow solution, transmitting the red, orange, yellow, and green rays to wave-length  $498.8 \mu\mu$ , divides the spectrum in two parts, namely, a slightly actinic half and an energetic chemically active half. It would also be interesting to thoroughly investigate the sensitiveness of orthochromatic plates to the action of all the less active rays. Orthochromatic plates may be divided into those which are sensitive to red or to green light. I have endeavoured to ascertain the sensitiveness of these two colours by means of two other colour filters, which also divide the less actinic half of the spectrum into two parts. The sensitiveness of the plates was determined in the following manner. Having made a hole in the wall of the dark room, I inserted therein a Dallmeyer lens and placed in front of it a spirit lamp with an incandescent burner rather nearer than the focal point. I found this light sufficiently constant, inasmuch as I obtained the same number from a series of exposures with the same kind of plates. The light filter was placed immediately in front of the lens. In the dark room I obtained a conical, divergent pencil of coloured light, and I placed the plate covered by the Warnerke sensitometer in such a position that the whole surface of the scale was illuminated. I had, of course, removed the phosphorescent tablet. The following plates were tested: Ilford Ordinary (yellow label), Ilford Chromatic, Edwards' Isochromatic, Lumière's Panchromatic, and Smith's Orthochromatic (red mark). I first ascertained the sensitiveness of the various plates by means of the phosphorescent tablet, and then tested their sensitiveness for coloured light. The numbers secured are given in the following table, the sensitiveness of the Ilford Ordinary plate being taken as the unit. With the red filter, however, the sensitiveness of the Ilford Chromatic plate was taken as the unit.

The Ilford Chromatic plates were found to be the most sensitive to green, and Lumière's Panchromatic to red. Smith's plates were found less satisfactory in both respects. These results brought me to the conclusion that for subjects in which green predominates it was best to use Ilford Chromatic plates. On the other hand, where red, warm tones predominate, Lumière's Panchromatic plates would do good service.

The application of monochromatic light filters and corresponding orthochromatic plates could, by means of Burinsky's\* system of colour separation, lend valuable assistance in the examination of doubtful documents. Moreover, it is easy to select from the light filters here enumerated, those which may be used with greatest advantage in conjunction with suitable orthochromatic plates for making negatives for reproductions by the three-colour process. In conclusion, I would draw attention to the following three-colour filters: (1) a solution of ammonio-oxide of copper (1 part of saturated solution of sulphate of copper + 6 parts of water + 1 part of ammonia; (2) a solution of mandarin (1 part of saturated solution + 1 part of water), which transmits the orange-red rays; (3) a solution of chloride of copper, which transmits only the yellow and green rays. These three in conjunction transmit the entire spectrum, and supplement each other. It therefore follows that, if the rays transmitted by these solutions are projected simultaneously upon a screen, we should have white light, but I have not yet had an opportunity to verify this. If, however, this conclusion is found correct, these light filters should be very suitable for Ives's Photochromoscope.

	Phosphorescent Tablet	Yellow Filter.	Green Filter.	Red Filter.
Ilford Ordinary (yell w label)	17 W. 1	2 min. 17 W. 1	2 min. 17 W. 1	20 min. No action. 0

## EDER'S EXPERIMENT CONCERNING THE LATENT IMAGE.

(Translated from the *Photographische Correspondenz*.)

THE following facts may perhaps contribute somewhat to the elucidation of the debate concerning the nature of the latent image.

It is known that the Eder experiment fails if pressure is absent when metallic silver is brought into contact with a bromide plate and subjected to development. This is explained by the fact that the area of contact is too small. In order to obtain satisfactory contact, the metal should be rubbed in as a powder, but this would give rise to the formation of an image due to pressure. To avoid this difficulty, the experiment can be made with a moistened plate. If we take a moistened plate and rub part of it with silver powder, and another part with some substance free from silver, such as powdered quartz or glass, the plate, when developed in presence of these substances and washed, will show that reduction has taken place under the influence of the silver powder, but not under that of the inert substance. A differential experiment will prove that the blackening of the film is not due to silver powder which has not been washed off. If we wash the plate before development, so as to remove the powder which has been rubbed upon it in the moist state, the developer will not cause any reduction. If we rub sub-bromide of silver upon the film in place of silver, the image will be much more intense. The former may be prepared by partially bromising silver. In consequence of pulverisation being more complete in this case, there is greater area of contact between the primary silver bromide, the developer, and the silver reduced from the silver sub-bromide. The intensity of the image is therefore greater for the same period of development.

With reference to the question as to the nature of the latent image, I am impelled to the conclusion, from experiments which will shortly be published in the *Zeitschrift für Physikalische Chemie*, that, if we exclude the presence of gelatine, both the latent and the visible images formed by light upon chloride and bromide of silver are sub-chloride and sub-bromide of silver, their respective chemical composition being  $\text{Ag}_2\text{Cl}$  and  $\text{Ag}_2\text{Br}$ . The experiments favouring the older opinion may be briefly stated as follows:—

Take a number of strips of glass covered with silver haloid, free from gelatine, obtained by deposition in presence of an excess of haloid, and expose them under a photometric scale. If we immerse them in a series of solutions, with potentials of oxidation for the said halogen ions, arranged in a descending scale, we shall find that the latent and visual images are destroyed by the solutions exceeding a certain potential of oxidation, and that they remain unaffected by the solutions below a certain potential. From this it appears very probable that the latent and visual images are formed of the same substance. These oxidising agents may be prepared by decomposing chromate-chromic solutions with various quantities of acid.

The visual and latent images of silver chloride were destroyed, that is to say, converted to  $\text{AgCl}$ , by a solution of

with an oxidation potential of about 1.5 volt. On the other hand, they were unaffected by a solution consisting of

with an oxidation potential of about 1.4 volt.

Bromide of silver was bleached by a solution composed of

with an oxidation potential of about 1.2 volt, whilst both images were left intact by a solution composed of

with oxidation potential of about 1.1 volt.

In order to obtain some explanation of the nature of the latent image, I took a weighed quantity of silver, and converted it to silver chloride, in stages by means of chlorine water, each addition containing  $\frac{1}{10}$  the quantity of chlorine that would suffice to convert the entire mass. After each addition, I ascertained with an electrometer the oxidation potential of the remaining chlorine. At first the oxidation potential remained constant at 0.55 volt, but suddenly sprang to 1.45 volts as soon as half the silver had been combined with the chlorine (corresponding to the combination  $\text{Ag}_2\text{Cl}$ ). It then remained fairly constant at 1.45 volt,

under the addition of further chlorine, until the whole of the sub-chlorine was converted to chloride of silver. A similar experiment with silver + bromine also gave a leap from 0.40 volt to 1.15 volt at the stage  $\text{Ag}_2\text{Br}$ .

As the transformation of the silver sub-haloids to normal haloids also takes place in the chromic solutions at the dividing lines represented by the respective oxidation potentials 1.45 and 1.15 volt, I think these experiments show that it is highly probable that the visual and latent images are of the composition  $\text{Ag}_2\text{X}$ , at least in the case of  $\text{AgBr}$  and  $\text{AgCl}$ , free from gelatine.

DR. R. LUTHER.

## THICKNESS OF FILM.

ON Thursday evening, October 12, Captain Abney (the President of the Camera Club) gave one of his attractive discourses at the Camera Club, the subject being an inquiry into the influence which the thickness of coating has upon the sensitiveness of a gelatine plate. The lecturer commenced his remarks by calling attention to the circumstance that, when light falls upon a photographic plate, a certain amount is reflected, a good deal passes through it, and some is stopped, and that in this stoppage the light must do work of some kind, whether that work be in the form of heat, electrical action, or chemical action. No plate is absolutely opaque, but will allow a considerable amount of light to filter through it.

Every one likes to work with a well-coated plate, and avoids one which has been half starved, because with the plate well favoured in this respect better results are obtainable. The reason why this is so does not trouble the ordinary worker, but a few experiments will make the reasons evident. It is an unfortunate thing that it is a physical impossibility to slice a gelatine film so as to divide it into different strata for the purpose of detailed examination, but we can arrive at much the same goal by taking a number of Kodak films, the coating of which is wonderfully uniform, and binding them together under pressure so as to form one compound film. He had taken six such films, pressed them into close contact, and exposed them to light for periods of 5, 10, 20, and 40 seconds, &c. The films were then separated, placed face upwards, and developed simultaneously. After fixing and drying, their opacities were measured by means of a Warnerke annulus, of which the lecturer showed a lantern slide.

The results showed that only seventeen per cent. of the light which fell upon the top film registered itself on the one beneath, while No. 3 of the series only received three per cent. Experiments showed that, if half the amount of silver had been used in the composition of the top film, forty-two per cent. of the light would have passed through it.

Once upon a time there were starved films of this character upon the market, and the lecturer had calculated that, if only one-third more silver were used, it would have increased their sensitiveness about ninety per cent.

A number of diagrams were shown in illustration of the various points touched upon, one especially being of a very conclusive character. It took the form of a number of squares, pieces of exposed plates all of the same brand, and presumably containing the same proportions of silver, but varying in thickness of coating. The thicker films showed a remarkable contrast in density to the thinner ones, although all had been simultaneously developed under precisely the same conditions.

Captain Abney said that his excuse for bringing these observations before the notice of the Club was the reflection that matters of theoretical interest may become of practical value. The study had been of extreme interest to himself, and he had felt that previous conclusions at which he had arrived would possibly have to be modified because he had failed to take into account this question of thickness of film. Small errors might in this way have crept in, but whether, in his busy life, he should ever find time to make the necessary corrections, a work which might occupy many months, he was unable to say. Perhaps one of his hearers might feel inclined to take the burden from him.

Sir H. Trueman Wood, who occupied the chair, remarked upon the valuable nature of Captain Abney's researches, but doubted whether the results of superposed celluloid films were comparable with one thick film such as might be attached to a glass support. He suggested that more reliable results might be gleaned by employing multiple films, each separated by soluble gelatine, so that the components might subsequently be separated for experiment. (Captain Abney here intimated that he had tried this plan and had obtained identical results as with the celluloid.)

Mr. Cadett, speaking from a manufacturer's point of view, said that the maker of commercial plates was heavily handicapped. No one would grudge a little extra silver in the plates which he made, but such generosity led customers to complain of slow fixation. People grumble, too, if plates take too long to dry. Beyond these difficulties there are some of a more practical nature. There is, first of all, the danger of precipitation, and, if to guard against this extra gelatine be added to the emulsion, the time of drying is enormously prolonged, which is no small matter in a climate such as ours. Captain Abney had experimented with separate films, but he had not, apparently, tried to cut sections from one film. In the course of coating a plate the larger grains are apt to sink downwards nearest the glass, and that part of the film is more sensitive than the top surface. He once took a jar of emulsion and

tested it for sensitiveness, finding that the lower part was six times more sensitive than the topmost layer.

Mr. Sanger Shepherd expressed the belief that the development of six separate films as described by the lecturer cannot give the same result as the development of a single film of a thickness equalling the six, because the development would take a certain time to work through the thickness of that one film.

After other speakers had joined in the discussion, the meeting was brought to a close by a few words from the lecturer, and a hearty vote of thanks to him for his admirable paper.

#### TECHNICAL CONTROL FOR PICTORIAL PURPOSES.

MR. W. THOMAS, F.R.P.S., lectured on the above subject before the members of the Leeds Photographic Society, on Tuesday, October 10. Mr. Godfrey Bingley presided over a large meeting.

At the outset of the lecture Mr. Thomas defined technique as being a full appreciation of the different implements available and of the variations possible by employing each or all as needful, together with a knowledge of the limitations inherent to photography and the means of minimising the effects of such limitations. When photography, however, was taken up for the sole purpose of pictorial expression, the lecturer claimed a wider definition, and asked that the utmost latitude should be allowed to each in their endeavour to interpret nature, at the same time pointing out that a light-made image is of such subtlety as to resent all but the most skilful interference, and that a boundary line must exist, beyond which it is dangerous to trespass.

Mr. Thomas urged the importance of workers becoming absolute masters of the tools employed. Until this was accomplished and a correct knowledge of relative light and shade acquired, it was not safe to play tricks in pictorial work, lest perchance suns be shining from all directions, and shadows where none could exist.

Dealing with practical matters in the field, the lecturer pointed out the necessity of having an absolutely rigid tripod, and, regarding the lens, it was necessary to have, not one, but several lenses of different foci, the superiority of long-focus lenses for pictorial work being explained and illustrated.

Focussing and the question of diffusion of focus was dealt with, and Mr. Thomas urged that each subject must have independent treatment in this respect, sharp definition being required in some cases, while in others a more or less amount of diffusion was desirable.

Treating of exposure, various slides and negatives were shown on the screen, the lecturer pointing out defects and how they might be overcome, and it was shown how a subject of great contrasts might be improved by control during development, the particular illustration being a pond in the foreground, lighted by the sunset sky, with a dark belt of trees in the middle distance, which had been saved by preliminary development in weak rodinal, the shadow portions being brought up by local application of stronger developer, the plate being frequently rinsed under the tap to prevent hard lines.

Mr. Thomas seemed to favour rodinal as a developer, and, when working, prefers to have three different solutions in hand, one of normal rodinal (1 in 30), a second of weaker rodinal (1 in 60 or 90), and a third, generally of hydroquinone, to give density. Working on these lines, it is possible to deal with plates having varied exposures by commencing development in the normal solution and transferring to the weaker rodinal or the well-restrained hydroquinone as the plate shows signs of under or over-exposure.

Isochromatic plates were strongly recommended as giving a more faithful representation of colour subjects, particularly in sky photography, and attention was called to their power, especially when used with a pale yellow screen, of clearing up mist or hazy distance should such appear too exaggerated.

A large number of slides were thrown on the screen, illustrating problems of exposure and questions of tonality, and it was shown how considerably the ultimate result might be controlled by an intelligent use of the factors of exposure, choice of plate, development, and after-treatment.

The subject was dealt with in a thoroughly practical manner, and was much appreciated by the audience, who, at the close, accorded Mr. Thomas a very hearty vote of thanks. J. C. C.

#### INDUSTRIAL EXHIBITION AT EDINBURGH.

THE Edinburgh and Mid-Lothian (Home Workers') Third Annual Competitive Industrial Exhibition (there's a lengthy title exhibition promoters may envy) was held in the Waverley Market, Edinburgh, last week. This Exhibition, taken all over, is a huge affair, with over 3600 entries, comprising almost every variety of home work, and it is a popular entertainment with the good folks of Auld Reekie. The photographic section has over 400 entries compared with 175 last year, and 35 classes compared with 15 last year. This great multiplication of classes seems a mistake, but probably Mr. Hutchinson knows the pulse of the visitors as to what they like and acts accordingly. As may be supposed this

Exhibition is visited by huge crowds—the Royal Engineers' Band is a great attraction—who would never think of entering a photographic exhibition. This opportunity of securing the attention of the general public is, with one or two exceptions, neglected by the professionals. The exhibits comprised, as might be expected, all qualities of photographs—good, bad, and indifferent—and, as might be expected with so much subdivision, some of the classes were poorly represented. Last year the photographs were exhibited on tables, but this year they were hung on screens erected in the Market, a considerable improvement, although the many conflicting lights were rather confusing; the arrangement of the different photographs also left much room for improvement. The Judges were Mr. Alex. Edington, F.S.I., President of the Edinburgh Photographic Society; Mr. John Warraok; Mr. R. Ayton, President of the Edinburgh Photographic Club; and Mr. Frank J. Moffat. Unfortunately, on the occasion of our visit, the second day of the Exhibition, the awards were not notified, nor was a prize-list available, so a detailed note of the awards is impossible. The special prize presented by the *Evening News*, in the open class, was awarded to Mr. Alex. Allan, Edinburgh, for *Load of Hay*, a picture that was medalled at the Edinburgh Photographic Society's Exhibition this spring. Mr. Allan is one of Edinburgh's most promising amateur exhibitors, and, it may be remembered, besides taking the prize last year, also took the "confined to members" gold medal at the Edinburgh Photographic Society's last show with *Mary*, a picture, by the way, that also appears in this Exhibition. In the "amateur" (which means in this Exhibition those who have never taken a first prize), the *Evening News* prize goes to Mr. T. A. Sands, Birmingham, for a summer landscape. Other leading prize-winners are Mr. Chas. M. Wane, Edinburgh; Miss Mary C. Eames, Llangollen; Mr. E. R. Collins, East Dulwich; Robert Puman, Edinburgh; Miss Buchanan, Edinburgh; Mr. John R. Clark, Whitehaven; Mr. W. G. Brown, Penicuik; Mr. W. J. Croall, Edinburgh; Mr. E. L. Brown, Edinburgh; Mr. J. K. Home Crawford, Portobello; Miss Fleming, Edinburgh; Mr. M. T. Anderson, Edinburgh; and Miss M. G. McLachlan, Blairgowrie. Mr. C. M. Wane had several good figure studies on exhibition, while his different examples of rapid-shutter work—horses leaping, &c.—were marvels of technique, while pictorial excellence was also evident, while his "swan" studies were as taking as ever. Mr. Byrne, Richmond, had hard lines with a number of lovely "child" studies, "too late for competition," and as a comrade in misfortune he had Viscount Maitland, who had a number of his well-known works forward, also unfortunately too late. Mr. W. F. Slater, London, had several good photographs forward, including his well-known *Pelican*, which had a duplicate in Class 41—at least as to subject. Mr. W. J. Croall's *Sporting Dogs at Work, Sunset on the Forth*, &c., quite held their place in the opinion of critics, while his *Greyhound* was a fine specimen of "doggy" portraiture. Mr. E. L. Brown had a well-arranged group of *Pomeranians* on show, but the colour hardly suited the subject. One was astonished to find a number of photographs entered in the name of a private competitor, with the words "Scottish Portrait Co." on the face of them. A disappointing feature was the large number of indifferent P.O.P. prints on exhibition.

If the managers would arrange to have the exhibits in proper order, with the prize-winners duly noted, they would remove the cause of the many complaints we heard from visitors during our walk round.

#### PHOTOGRAPHY APPLIED TO TEXTILE DESIGNS.

In the opening of the twenty-sixth session of the evening classes at the Textile Department of the Yorkshire College at Leeds, on Wednesday evening, the 11th inst., Professor Beaumont gave an account of the new photographic method of preparing textile designs invented by Jan Szczepanik, which he had recently been studying in Paris. The object of the appliances, it was explained, was by mechanical means to enlarge the artistic sketches of the designer, and to transfer the design to ruled or point paper marked with millions of dots arranged in the order proper for the development of the pattern in the weaves. Szczepanik printed the design by a photographic process on sensitised paper, and by his method the process of applying the weaves was governed, not by the skill of the artist or his assistants, but by natural laws. Inaccuracies in shading were thus made impossible, for the change in the weave is absolutely identical with the toning of the negative. Designs which now took weeks, and even months, to prepare for the loom would by this new method be mechanically worked out in a few hours. For instance, in six hours a design in silk tapestry, 176 square centimetres, or about 35 square inches, in extent, had been prepared. It might be imagined that this ingenious and novel invention was calculated to have an important influence upon the branches of the weaving industry relating to the manufacture of all elaborately figured fabrics, especially if the designs worked out photographically were legible for all practical purposes. It was recognised, of course, that there must be limitations to its utility, as there were to all mechanical and automatic appliances. Yet, if it could be employed in accelerating the process of designing large patterns, it should have the serious attention of all who desired the further development of the weaving industries. It was a mistake to think that, if the invention became commercially useful, the sphere of the designer would be considerably restricted. In the long run, innovations of this kind,

though at first they might dislocate certain branches of employment, enriched the industry in whose interests they had been introduced. The place of the designer, the brain worker in textile factories, could not be assumed by inventions of this kind.

The chair of the lecture was occupied by Mr. G. H. Nursey, vice-chairman of the Textile Industries Committee, and over 500 manufacturers were present from all parts of the country.

### VICOL.

At a meeting of the London and Provincial Photographic Association, on October 5, Messrs. Berger & Co.'s representative attended to describe and demonstrate Vicol printing out paper for the quick and easy production of coloured photographs. The paper, it may be explained at the outset, is made with matt and glossy surface, and, whichever it may be, it always presents a rose tint before toning and fixing, after which turning to a delicate mauve. Printing is done in the same way as with ordinary P.O.P. The prints are then washed for ten minutes in running water or several changes, and afterwards soaked for two or three minutes in—

Common salt .....	1 ounce,
Water .....	20 ounces,

with constant motion. After a further washing for ten minutes, the prints are ready for toning, and any recognised bath will serve. The following is, however, especially recommended:—

A.	
Ammonium sulphocyanide .....	150 grains.
Water .....	15 ounces.

B.	
Gold chloride .....	15 grains.
Water (distilled or boiled) .....	15 ounces.

Two ounces of A added to 16 ounces of water, mixed with 2 ounces of B, constitute the bath. After toning, the prints are washed for five minutes, and then immersed in a freshly mixed fixing bath, made up of—

Hypo .....	3 ounces.
Water .....	20 "

The final washing should be for about an hour, but in hot weather this may be followed up by treatment in an alum bath for five minutes—

Alum .....	1 ounce.
Water .....	20 ounces.

The hardening bath must be followed by five minutes' washing before any colouring is attempted. For the colouring process three solutions are required as follows:—

- A. Citric acid, 5 ounces in 95 ounces of water.
- B. Sodium hydrate, 3 ounces in 97 ounces of water.
- C. Pyrogallie acid, 1 ounce in 99 ounces of water.

Smaller quantities may, of course, be made, but the proportions must be preserved. The mounted prints are then taken, and the solutions applied with a camel's-hair brush, the surface of the print being previously lightly sponged. The A solution gives flesh tints, the B solution blue tones. Green is obtained by following up B solution with C solution, the depth of the green varying with the strength of the C solution. The weaker the C solution, the paler the shade of green obtained, but, if it should be too strong, the colour will tend towards brown. Brown and buff-yellow tints are secured by first proceeding as for green, followed after the surface has dried by solution A. A strong C solution gives deep browns, and it must be well diluted for yellow tints. The process has its advantages and disadvantage. One of the former is its cheapness. A few pennyworths of chemicals will make solution sufficient for many years' use. Washing soda generally contains enough sodium hydrate for the purpose, and may be used in place of the hydrate. After cheapness may be mentioned the advantage it offers to the professional. Hitherto not much colouring work has been done by professionals because of the time it calls for by other methods. Vicol, however, renders the delicate work of colouring the face a matter of but a few seconds. Another advantage named was that skill and care were not absolutely essential, and it was shown that, though one might splash the solutions about, the final result need not suffer. The process presents a cheap and tasteful method of preparing show cards, menu cards, &c., in colours by photographic means, and for landscape work it also has much to commend it, nearly every shade of green as well as brown being now possible. Before proficiency is acquired, it may be necessary to experiment on a packet or two of paper; but, on the other hand, some hit success from the first. Vicol should be specially useful in medical and X-ray photography, where the flesh, the veins, and the bones could be differently coloured, and for machinery photographs it is expected to compete with the ferro-prussiate process. The demonstrator proceeded to colour a number of prints before the meeting, showing the suitability of the process for portraits. If the matt paper be used, the general flesh tints of the citric acid solution may be enhanced by crayon or other working up. The makers only ask for a fair trial of the paper. Many had exposed the results to conditions which it would not be possible for any coloured photography to

withstand, in direct sunlight and so on, and yet were surprised at their going off. The colouring could be as easily done before the mounting of the print; in fact, as it is taken from the washing water as after it is mounted. A great deal depended upon well sponging the coloured print when dry with water to remove any excess of acid, &c., and, if this be done, the result should be as permanent as by any other process. The speaker laid some stress upon the mountant being neutral.

Mr. Walter D. Welford said he had tried the paper, and showed his results. He found no great difficulty in mastering the process, and had only failed once. His prints were far more delicately tinted than most of those shown, and in some cases efforts at translating a sunlit sky had been made. He found that the pyro solution was very strong at one per cent. He diluted this again considerably with every success. He found, as it was stated, that the toning formula was unimportant, and had employed the bicarbonate bath. He found nothing gained by sponging the surface of the print before tinting. It was easier to manage dry. The caustic soda played havoc with the camel's-hair brushes, but he was told that a hog's-hair brush might be used instead.

A long discussion ensued, chiefly upon the claims to permanence which are made for the process and other points of detail, and the meeting closed with a hearty vote of thanks to the demonstrator and his assistant.

### SIMULTANEOUSLY OPERATING ANIMATED PICTURES AND THE PHONOGRAPH.

In this device, which is the invention of Herr Malke, to the shaft, D, is attached the pinion which drives the transport wheel for the block of pictures, and this shaft carries a worm wheel, B. E is the operating shaft for the phonograph, having a disc, or the gramophone, with the well-known roller, and the shaft, E, carries a second worm wheel, C. Transversely to the shafts, D and E, is mounted a shaft, A, having thereon two

worms, one engaging the wheel, B, and the other the wheel, C. The shaft, A, is coupled by means of a flexible shaft, G, to the driving shaft, F, and thus, when set in motion, drives both the shafts, D and E.

The advantage of the flexible connexion, G, is that the working of the parts is very quiet and even; and then, again, in accordance with this arrangement, the worm shaft, A, and the driving shaft, F, need not necessarily be in line or concentrically arranged.

### "SPIRIT PHOTOGRAPHY" BY FLASHLIGHT.

According to an Australasian contemporary, Mr. Mark Blow, of the Crown Studios, Sydney (N.S.W.), has had the temerity to attempt to catch the spirits on the hop. He had the good fortune to be present at a séance when Madame —, a professional medium, called forth her attendant spirits, and so the daring photographer, by invitation, put in an appearance, well equipped with a reliable camera and instantaneous plates. The lens was carefully directed to the exact spot where the other-world visitors were to present themselves. After some time of anxious waiting a gentle voice announced, "The spirits are ready." Mr. Blow had no time to spend in posing, as his bent desire was to de-

pose. In an instant the flashlight fizzed and the deed was done. Again everything was still, save the quiet reversing of the dark slide in the camera, when the voice of the medium, in a gentle "Here they are again," let the photographer know this was his opportunity. Another flash followed, and the spirit-slayer felt satisfied, if there be any impressions for the plates, he had secured them. What care and anxiety Mr. Blow displayed in developing those negatives we must leave him to tell. It was not a case of either under-exposure or over-exposure; neither pyro ammonia, pyro soda, nor all the new developers combined, could draw from those faithful plates a testimony that they had seen anything. Either one of two things must account for the absence of an impression, the plates were not quick enough for the spirits or the spirits were too quick for the plates. One thing is very evident, the spirits can't stand the flashlight.

#### A PLATE-WASHING APPARATUS.

THIS apparatus, the invention of Herr Geiger, consists of a frame constituted by a bottom plate having an undulating, corrugated or ribbed upper surface, provided with lateral guide rods, and a water reservoir adjustably arranged on said guide rods and provided on its under surface also with undulations, corrugations, or ribs, which undulations are provided with a series of small oblique perforations arranged close to each other and directed towards one side, through which the liquid is intended

to issue in spray against the film side of the plate, which plates are held between the two corrugated plates.

The corrugated plate, *a*, is provided with feet, *b*, and with a bent guide rod, *c*, or vertical rods on which slides a suitably shaped water reservoir, *d*, which can be fixed in any vertical position on the rods by means of set screws, *e*. The reservoir is provided at the top with a pipe, *f*, for

receiving an indiarubber tube, *g*, through which the water is admitted to the reservoir. The bottom, *l*, of the reservoir, *d*, is corrugated, the corrugations of which are provided with rows of perforations, *m*, directly obliquely downwards, for the purpose of directing and spraying the water from the reservoir, *d*, on to the film side of the plates, *p*, the plates being held between the bottoms of the upper and lower corrugations, *a* and *l*, respectively. On one side of the sides of the water reservoir, *d*, is

arranged a bent metal strip, *h*, provided with a longitudinal slot by means of which it can be adjusted as regards length and secured by a screw, *k*, in order to support the apparatus in an inclined position, which metal strip is secured, when not required, by a small screw, *n*, as shown in figs. 3 and 4. When the washing or treatment of the plates, *p*, is finished, the apparatus is tilted into an oblique position for the purpose of allowing the water to run off and the air to pass freely through, and is propped up by means of the metal strip, *h*, the latter having been fixed to the required height, as shown in fig. 6.

In order to treat in this way, and simultaneously, several plates of

different heights, a special device is provided, which consists, as represented in fig. 2, of a metal strip, *w*, bent so as to fit into a corrugation of the plate, *a*. This metal strip is provided with two or more tubes, *r*, projecting upwards, provided with rods, *s*, the height of which is made adjustable by means of set screws, *t*. These rods carry at their other ends a bent metal strip, *v*, corresponding in direction with the corrugations of the lower supporting plate.

#### ILLUMINATING ANIMATED PHOTOGRAPHS.

In this device of Herr E. Maile the animated pictures are produced from a block of leaves containing pictures of a series of successive positions of a moving figure or of moving figures. The block containing the leaves, *a*, is mounted on a suitable base plate, and this plate is moved by suitable means under a bar or bow, *b*, so that, as it passes under the same,

the leaves are rapidly turned over, and the effect of an animated picture attained. The base plate may be moved by a star or chain wheel, *c*, which engages in orifices in the bottom of the said plate, or by any other means.

The means for illuminating the pictures as they are produced consist of a source of light, *n* (lamp, or the like), having arranged there-around a cylinder of polygonal cross section, as at *A*, the sides of which are of different coloured glass, or other translucent material. This cylinder, *A*, is mounted to rotate on the stand of the lamp, or other source of light,

and advantageously provided at the bottom with a gear, c, which engages an intermediate gear, v, suitably mounted on the supporting plate of the apparatus. The gear, v, engages a rack, z, mounted on the base plate

of the block of pictures, and obviously, as the block is moved forward as previously mentioned, the rack, z, will rotate the gear, v, and with it the gear, c, and translucent mantle, a, of the lamp. Thus the pictures,

as they are produced, will be illuminated with a light which constantly changes its colour, and a very pretty effect will be attained.

Instead of a mantle, a, enclosing the source of light, b, a disc, r, may be employed as shown at figs. 3 and 4, the said disc being mounted in

front of an electric or other light, and between it and the effective surface of the pictures. This disc may be provided with various colours, and must, of course, be translucent. The disc may be rotated from the

driving shaft of the star wheel, c, by means of a cord or chain, r, and wheels, n and k.

In figs. 5 and 6 a device is shown for reflecting light on to the picture as it is produced. This device consists of a reflector, x, pivotally mounted in slots, q, of a supporting frame, o, which is mounted on an expansible set of levers, p, known as "Nuremberger scissors." This set of levers is also adapted to turn on its pivot on a segment, r, fitted to the base plate of the apparatus, as will be evident from fig. 6, so that the reflector may be adjusted to any desired position as regards the picture.

### A THIRD EYE.

"Did man once possess a third eye?" is a subject that is just now going the round of the newspapers. One of them assures us that deep researches as to the structure of the human body have recently furnished some startling facts regarding changes which man is at present undergoing physically.

"It is believed that man was formerly endowed with more teeth than he possesses now. Abundant evidence exists that, ages and ages ago, human teeth were used as weapons of defence. Unintentionally, traces of such use are often revealed by a sneer. The teeth are sometimes bared, doglike, ready, as it were, for action.

"The practice of eating our food cooked and the disuse of teeth as weapons are said to be responsible for the degeneration that is going on. The wisdom teeth, in fact, are disappearing. Human jaws, found in reputed Palaeolithic deposits, have wisdom teeth with crowns as large as, if not larger than, the remaining molars.

"In ancient times a short-sighted soldier or hunter was almost an impossibility; to-day a whole nation is afflicted with defective vision. It is almost certain that man once possessed a third eye, by means of which he was enabled to see above his head. The human eyes formerly regarded the world from two sides of the head. They are even now gradually shifting to a more forward position."

As a specimen of amusing speculation, this sort of thing perhaps has merits, but there is absolutely no evidence forthcoming that the human race was once endowed with a third eye. Its uses are not obvious.

### WINDOW PICTURES.

[From the Catalogue of the Croydon Camera Club's Exhibition.]

Our Exhibition has perhaps nothing which will give more general pleasure to the majority of its visitors than the display of transparencies, or, as they are sometimes rather pedantically called, diapositives, with which Mr. Henry Stevens has favoured us.

Writing more for the casual visitors, be they amateurs or not, rather than for the old hands, let me explain that Mr. Stevens is anything but an unrecognised novice. Quite the contrary, he has received the distinction of being invited to hold a *One-man Exhibition* at the London Camera Club, when nearly a hundred of his transparencies formed the chief centre of attraction. Since then a selection was, by special request, shown, and greatly admired at the Imperial Institute. In fact, these transparencies have everywhere always evoked warm expressions of delight and appreciation, except, alas! at the leading Society's Exhibition, that of the R.P.S., where, at least on one occasion, these exquisite examples of one of photography's most inimitable and charming characteristics were displayed in such a way that the visitors who wanted to see them had to crawl on all-fours. This year Mr. Stevens does not exhibit at the Royal. Perhaps it is for similar reasons that there are this year at the same exhibition such a beggarly array of lantern slides.

### HOW TO MAKE WINDOW PICTURES.

Those who have seen our collection will all of them naturally long to possess similar photographic products, and such of them as are amateurs will like to know whether there exists any great difficulty to contend with before obtaining such results as Mr. Stevens has achieved.

In a word, there is no trouble or difficulty whatever, more than is met with in making bromide prints or lantern slides, except that one *must*, in order to get such results as are exhibited, start with a technically well-made negative. A negative which is quite good enough for producing an art result when printed through a dish cloth won't do at all for transparency work.

The negative should be perfectly sharp at the centre of pictorial interest, and, and not much "unsharp" anywhere else. Such gross out-of-focussing as produces blobs of light, instead of definite form, is out of the question. Staining, halation, and lack of gradation are all to be carefully avoided. Although the negative should be preferably of average density, an excessive density is no bar to the obtention of a good transparency, as is illustrated by Mr. Stevens' picture of *The Hyacinthus candicans*, the negative of which was so dense that the exposure of the transparency plate in full sunlight was twenty minutes.

One consideration which, no doubt, stands in the way of the average amateur is that the original negative needs, in order that fairly large transparencies be made, to be of considerable dimensions. This means

trouble and expense. Although any enlargement is apt to impair the brilliant definition which forms a strong attraction with a transparency, it is quite possible to obtain very satisfactory results by enlarging up to two diameters. Thus a whole-plate negative will yield an excellent 12×8 transparency. That this may result it will be useful to use a lens of full covering power, well corrected for astigmatism, and well stopped down.

As regards further technical data, for which the writer is indebted to Mr. Stevens, the best developer is amidol, not but what pyro ammonia will very well serve. In using amidol, the main risk is in over-exposure and under-development. Potassium bromide, used as a restrainer, is apt to spoil the colour of the image. A certain amount of over-development is called for with amidol, as the image goes back in the hypo.

Although any good transparency plate, such as Thomas's or Cadett's, may be used, Mr. Stevens has produced most of his exhibits upon Mawson & Swan's plates.

Those who are further interested in Mr. Stevens and his work in transparency-making will find an article by me in the August number of the *Camera Obscura* dealing more fully with the subject.

Before closing these notes, attention is drawn to the picture called *Worn Out*, as being the one which received the first prize of fifty guineas in the *Graphic* competition.

#### PLATINOTYPE TRANSPARENCIES.

Those who take fuller interest in the subject of window decoration by means of photography are reminded that the application of *platinotype* prints to glass results in very satisfactory transparencies. Visitors who require more information on this point are referred to Mr. W. H. Smith, who will attend the Exhibition every evening (except Monday, the 22nd) on behalf of the Platinotype Company.

HECTOR MACLEAN.

#### MONTHLY LANTERN MEETINGS AT THE R.P.S.

The Assistant Secretary of the Royal Photographic Society writes:—

"I have much pleasure in informing you that the Council have decided to institute a monthly meeting specially devoted to illustrated lantern lectures. These meetings will take place on the first Tuesday in each month, from November to April inclusive, and will commence at eight o'clock p.m.

"The first lecture of the series will take place on Tuesday, November 7, at the Gallery, 5a Pall Mall, East, when Mr. J. J. Vezey will give a lecture upon 'Some Mediaeval Towns of Germany,' illustrated by lantern slides by Commander C. E. Gladstone, R.N.

"The Council wish it to be understood that lady visitors are specially welcome on these occasions, and tickets may be had on application to me."

## Our Editorial Table.

#### SPECIMENS OF DEVELOPED GELATINO-CHLORIDE PRINTS.

J. P. Mayall, Limited, 10, Rye Hill-park, Peckham Rye, S.E.

SINCE we first referred to the photographs on gelatino-chloride paper produced by a system of development and toning which Messrs. Mayall have worked out, opportunity has been given us of examining a very large number of prints of great dimensions that have recently been made for commercial purposes. This inspection confirms us in the opinion we originally expressed on the subject. Messrs. Mayall appear to be extremely successful in obtaining uniformity and depth of tone in large numbers of gelatino-chloride prints, and we are not surprised to hear that many good judges amongst professional men have favourably criticised Messrs. Mayall's work. Certainly a process for developing gelatino-chloride prints which yields certainty and uniformity of results over a large number has a very great deal to recommend it, and Messrs. Mayall should receive considerable patronage in their attempts to popularise their process amongst photographers.

#### CATALOGUES RECEIVED.

W. Butcher & Sons, Blackheath, S.E.

At this season of the year, when the attention of so many photographers is concentrated on optical projection work, the catalogue of lantern accessories and slides which Messrs. Butcher are issuing should be found of great service for reference. It extends to about 260 pages and between its two covers gives particulars of all the apparatus a lanternist is likely to require. The slide section occupies over fifty pages. We advise all lanternists to procure a copy of this catalogue.

J. E. Johnson & Co., Rostellan Screen Plate Works, Gnthlaxton street, Leicester.

In this handsomely produced catalogue Messrs. Johnson give particulars of the screens for half-tone work which they prepare, and they include many beautiful reproductions of photographs made by screens the lineatures of which range from 100 to 250 lines to the inch. We advise all interested in half-tone work to procure this list. It may be remembered that Messrs. Johnson were awarded a medal at the Royal Photographic Society's Exhibition for one of their engraved screen plates.

## News and Notes.

PHOTOGRAPHIC CLUB.—October 25, at eight o'clock, Travellers' Night. "To Trieste and Back by Cycle," by C. Dalgarno.

MESSRS. BENDER & Co., of 242, London-road, Croydon, have been awarded the first prize at the German Convention in Baden-Baden for carbon and bromide enlargements.

THE AUSTIN-EDWARDS MONTHLY FILM NEGATIVE COMPETITION.—The prize camera for the current month has been awarded to Mr. J. B. Smith, 38, Albion-street, Brooks's Bar, Manchester, for his negative, *Study of Two Swans*.

ROYAL PHOTOGRAPHIC SOCIETY.—Technical Meeting, Tuesday, October 24, at 5a, Pall Mall East, at eight p.m. Mr. Harry Wade will read a paper upon the "Wellington Film." The following lantern fixtures are arranged for the Pall Mall Exhibition:—Monday, October 23, "North Country Life and Scenery," by Mr. E. G. Lee; Wednesday, October 25, "Olla Podrida," by Mr. Tom Bright; Saturday, October 28, "Lowestoft and Neighbourhood," by Mr. H. Vivian Hyde.

THE NEW WELLINGTON film was the subject of an interesting description by Mr. Harry Wade at the Borough Polytechnic Photographic Society on October 11. The various operations of exposing, developing, and finishing were most clearly demonstrated, and, from the discussion which followed, the new film must seem to possess many advantages over the familiar glass plate, and more particularly for the purpose of enlarged negatives. On Wednesday, October 25, Mr. John A. Hodges, F.R.P.S., is to give a lecture on the "Pictorial Treatment of Lantern Slides," and the Society extends an open invitation to all who are interested. The meeting commences at 8.30 p.m.

"AS OTHERS SEE US."—The July issue of THE BRITISH JOURNAL OF PHOTOGRAPHY, in a supplement, gives a group of the attendants of the Fourteenth Annual Convention of Photographers of the United Kingdom. A finer-looking gathering is seldom seen of any profession. They range from young men scarcely above their teens to venerable men, whose heads are whitened with age, and a sprinkling of ladies. In that group is concentrated the photographic wisdom of the kingdom. May long life, continued wisdom, and great power be allotted to each of them as they dispense their knowledge of and interest in the useful, beautiful, delicate, mystic art of photography.—*St. Louis and Canadian Photographer.*

THE HOVE Camera Club's Fourth Annual Exhibition will be held at the Town Hall, Hove, on Thursday, Friday, and Saturday, December 7, 8, and 9, 1899. The Judges are the Rev. F. C. Lambert and Messrs. E. E. Mainwaring and C. H. Burleigh. The following are the open classes:—A, Champion Class for pictures (any subject) which have previously gained an award. B, For pictures (any subject) which have not gained an award in open competition. C, Lantern slides (any subject), in sets of four. D, A set or sets of four pictures by exhibitors who have never gained an award in photography. In each of the above classes silver and bronze medals and certificates will be given. Class D, silver medal presented by Mrs. A. O. Jennings. Entry forms and further particulars can be obtained from the Hon. Secretary, Mr. C. Berrington-Stoner, 24, Holland-road, Hove.

MR. J. J. SADLER, of Horsforth, near Leeds, informs us that he has been appointed special agent for the new radial adjustable photographic printing frame by the sole proprietor and manufacturer, Mr. G. V. Yates, of Sheffield. Mr. Sadler points out that there is a growing demand for small photographs at a reasonable cost, and which can be produced by means of artificial light (gas or electric) in a very short space of time. The advantages of this frame are stated to be as follows: 1, Simplicity; 2, one can print twelve portraits on a half-plate sheet of paper (the new Victoria size); 3, the saving of seventy-five per cent in plates, as the size of a negative is a fourth of a quarter-plate; 4, the saving in retouching, as there is only one negative; 5, no new apparatus (camera or lens) required; 6, artificial light can be used, so that the work can be done at any time; 7, exposure about five seconds. Full instructions are sent with every frame.

THE Essex and Middlesex Cycling Union, which last year threw its annual Photographic Competition open to all comers, has this year gone in for further extension. It has joined hands with the Cripplegate Photographic Society, and together they will run the sixth annual competition on most liberal lines. No money prizes are offered as the policy of the two promoting bodies is to foster amateur competition. Twenty-five medals are put up for the nine classes, in addition to diplomas for exhibits of sufficient merit. The open amateur classes are: Portraiture and Figure Studies, three prizes, gold, gold centre, and silver medals; Land or Seascape, gold, gold centre, and silver; Cycling subjects (set of four), gold centre and silver; Hand-camera subjects (set of six), gold centre and silver; Beginners' Class, silver and bronze; and Lantern slides (set of six), gold centre and silver. The open Professional Class is for any subject, the prizes being gold, silver, and bronze medals. The pictures will be exhibited at a three days' Exhibition (December 5 to 7) at Cripplegate Institution, Golden-lane, London, E.C., and they will be held covered by insurance against fire and theft whilst in the possession of the management. Entries close November 13, and pictures have to be delivered by November 27. Two well-known Judges will be appointed. Entry forms and fuller particulars can be obtained on application to either of the Hon. Secretaries of the Competition, Mr. A. T. Ward, Cripplegate Institute, Golden-lane, E.C., or Mr. G. F. Sharp, Falford House, Sach-road, Upper Clapton, N.E.

JUDGMENT RESERVED.—At the Grimsby County Court, on Thursday, George H. Eustace, photographer, Cleethorpe-road, Grimsby, sued G. E. W. Woodall, 17, East Marsh-street, Grimsby, for 12. 5s. Mr. Tonge appeared for the plaintiff and Mr. Barker for defendant. Mr. Tonge said the action was for improperly refusing to accept the delivery of the goods ordered. On April 28 defendant went to plaintiff and wanted a photograph of his wedding group. The negative of that photograph was—

taken by plaintiff's predecessor in the business. Plaintiff looked up the negative, and told them it was not a very good negative, and he suggested defendant should have a bromide enlargement of the picture worked up by hand. This was agreed to. Mr. Barker (pointing to the goods handed in by him): "This is the photograph and this is the enlargement." Mr. Tonge: "That is all we have left." Plaintiff said that a part of the group had been left out according to instruction. Subsequent to the completion of the enlargement the goods had been refused. A better job could not be made of it from the particular negative he had. It was a bad one. It was a very thin negative. He told defendant that Mr. Barker: "You say on your business cards, 'Satisfaction guaranteed.' Do you consider you have given Mr. and Mrs. Woodall satisfaction?" Plaintiff: "A satisfactory job has been made from the negative." Defendant's wife was called, and stated that plaintiff had said that he could make a good job of it, but the enlargement did not give satisfaction. Her husband said it made him look blind in one eye. His Honour asked witness if she was satisfied with the enlargement of herself. Witness: "I don't know." His Honour said he was not satisfied that plaintiff had made a good job of this matter. He would look at the photograph, and give judgment at the next Court.

## Patent News.

THE following applications for Patents were made between October 2 and October 7, 1899:—

FINDER.—No. 19,709. "A Distance-finder for Photographers." Communicated by J. H. GLASSPOOL. C. SPENCER.

BAS-RELIEFS.—No. 19,817. "A New Method of obtaining Bas-relief Photographs, Photogravures, or any Print where an exact Duplicate is to be obtained." A. J. E. HILL and PHOTO, LIMITED.

COLOUR PHOTOGRAPHY.—No. 19,843. "Improvements in Colour Photography." L. A. GARCHY.

SWING BACK.—No. 20,012. "Improvement in Swing Back for Photographic Cameras." Complete specification. W. F. CARLTON and H. W. LOCKE.

PRINTING MACHINES.—No. 20,024. "Improvements in Photographic Printing Machines." H. LOESCHER.

PLATINOTYPE TIN.—No. 20,112. "An Improved Storage Tin or Platinotype Paper." C. H. PRICE.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
23.....	Bradford Photo. Society .....	Stratford-on-Avon. Harold Baker.
23.....	Kington-on-Thames .....	Orthochromatism. James Cadlett.
23.....	Oxford Camera Club .....	Photographing Objects in Motion. H. M. Underhill.
24.....	Birmingham Photo. Society ..	Photographic Mounts. P. T. Deakin.
24.....	Croydon Camera Club .....	W. T. Greatbatch, and B. Moore.
24.....	Hackney .....	Soiree and Prize Distribution.
24.....	Royal Photographic Society ..	Negative-making. Rev. F. C. Lambert.
25.....	Ashton-under-Lyne.....	Wellington Film. Harry Wade.
25.....	Photographic Club .....	Demonstration: Messrs. Wellington & Ward's Negative Films. Harry Wade.
25.....	West Surrey .....	To Trieste and Back by Cycle. C. Dalgarno.
25.....	Camera Club .....	Discussion on the Current Exhibitions.
26.....	London and Provincial .....	Illusions and Anomalies of Vision. Shelford Bidwell.
27.....	Bristol and West of England ...	Open Night.
27.....	Leeds Photo. Society .....	Demonstration: The Tella Hand Camera. W. E. Dunmore.—Lantern Evening: Society's Collection of Members' Slides.
27.....	West London.....	Demonstration: Enlarged Negatives. Percy Sheard.
		President's Annual Address and Members' Slides.

### ROYAL PHOTOGRAPHIC SOCIETY.

OCTOBER 17,—Mr. Chapman Jones, F.I.C., F.C.S. (Vice-President), in the chair.

Mr. H. W. Bennett was in attendance, and prepared to read his paper on "Architectural Photography," but owing to the fact that the *Soiree* of the Photographic Salon was taking place, there were very few members present, and the Chairman therefore suggested that under the circumstances it would be unfair to ask Mr. Bennett to deliver his discourse to so small an audience. He accordingly took a vote as to the advisability of postponing the meeting, and the majority being of that opinion, the proceedings were adjourned.

### COMING EVENTS.

October 24, "The Wellington Film," by Mr. H. Wade. November 7, "Some Mediaeval Towns of Germany," by Mr. J. J. Vezey, with illustrations from photographs by Commander Gladstone, R.N. November 14, the Traill Taylor Memorial Lecture, "Teachings of the Daguerreotype," by Major-General Waterhouse, I.S.C. November 21, Mr. H. W. Bennett will read his paper on "Architectural Photography."

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 12,—Mr. R. Child Bayley in the chair.

Mr. W. D. WELFORD said he had received a print from the member who, at the last meeting, mentioned that a certain coloured print by the Vicol process had lost its colour in a very short time. The print upon which this complaint was based was handed round, and the alleged fading was very obvious, especially when the print was seen alongside a freshly made print. The want of permanence exhibited in the case shown was in respect of the colouring only, the photographic image being quite satisfactory.

Mr. A. L. Henderson, who was heartily welcomed on his return after his long absence through illness, showed a number of slides of views in and around Aix-les-Bains, which, with its lake, mountains, and scattered houses and villas, offers considerable opportunities to the photographer. Many of the pictures were typical of the place as showing the sulphur, medicated, and hot-air baths and massage establishments for which Aix is noted, and there were several views of the interiors of these buildings.

Mr. T. E. Freshwater contributed some fine yachting pictures by the well-known firm of West & Son, of Southsea. They were especially interesting as including a view of this year's challenger for the American Cup, *Shamrock*, and other notable prize-winners, *Rainbow*, *Satanita*, *Narahoo*, &c. He also showed some slides of Dover and Norwich, and others of a miscellaneous nature were exhibited by Mr. Jarvis and Mr. Emery.

### PHOTOGRAPHIC CLUB.

OCTOBER 11,—Mr. J. R. Williams in the chair.

The Chairman showed one of McKellen's Phoenix hand cameras, the distinctive feature of which is the focussing arrangement, which allows of focussing upon a full-sized screen with one lens only. To this end a mirror is placed before the plate at an angle of 45°, the image appearing upon a screen placed at the top of the camera. By pressing a button the shutter is released, the same movement lifting the mirror up out of the path of the rays of light.

Some discussion took place upon the question of dusting plates, and it turned out that all the practical photographers present found it safer never to dust a plate, especially those of large size. This, being contrary to the preachings of the recognised text-books, seemed very regrettable. It was pointed out that a brush was, moreover, a most dangerous instrument for the purpose and that, if dusting be thought advisable, a pad of some sort should be preferably used.

Mr. WALTER D. WELFORD mentioned the enormous latitude in exposure which ortol allowed. As an instance, he cited the case of a cloud negative which had been about ninety times over-exposed, but which, developed in an old ortol solution, was saved from a bad end. It differed in no way from a correctly exposed plate upon the same subject, developed in the same developer. Mr. Welford said he had given up pyro entirely, and, from the discussion that ensued, it transpired that pyro was fast going out of use. *Requiescat in pace.*

**Camera Club.**—Last week the Camera Club settled down to serious business, and most of the well-known faces were to be seen there. Upon the walls of the large room are now hung a series of pictures by Mr. Ashton, who is the photographer, *par excellence*, of Eastern scenes. Year after year has he contributed to one or other of the exhibitions pictures of Eastern life, such as the interior of a barber's shop in Algiers, or a gossip in a café at Constantinople. One of the best of the present Salon pictures is from his camera, and now, at the Club, he has an Exhibition all to himself. The photographs are not many in number, but their quality is very high. On Monday there was a little disappointment in store for the members. The versatile Dr. Lindsay Johnson had been announced to discourse upon, and demonstrate, a new form of phonograph, but at the last moment the giddy thing refused to speak, and it had to be kept at home like a naughty child. But the members had by no means a blank evening, for Mr. Middleton was prevailed upon, almost at an hour's notice, to give one of his charming extempore lectures upon architecture. It is given to few to be ready at such short notice with a good lecture and a superb set of pictures with which to illustrate it, but Mr. Middleton is one of the few, and his valuable services are always at the disposal of his friends at the Club. Continental Gothic architecture is a very wide subject indeed, and Mr. Middleton made it wider still, by tracing its origin, and showed us how the early pilgrims, who wandered East before the time of the Crusaders, brought back with them impressions of the architectural features which they had seen in the far East; how these new forms gradually penetrated through the valley of the Rhine, and influenced the builders of all the noble churches to be found there. Then Mr. Middleton took his audience through Northern France, through Normandy and Brittany, and thence to Belgium and Germany, pointing out little differences in the treatment of stonework or ironwork which ordinary observers would pass by without notice. And not only was the lecture illustrated by an excellent series of pictures, but by admirable sketches of details which were hung around the room for after-examination. Mr. Middleton had an appreciative audience, and was thanked by all for his excellent lecture as well as for his kindness in giving it at such short notice. Wednesday was a Ladies' Night, when, of course, all technicalities were laid aside, and music, lantern slides, the phonograph, and suchlike frivolities held sway.

**North Middlesex Photographic Society.**—October 9, Mr. R. Child Bayley in the chair.—Mr. ERNEST MARRIAGE gave a lantern lecture on

### TELE-PHOTOGRAPHY.

The lens, the lecturer said, he used, was of a portrait type, working at  $f/3$ , with a negative attachment, which allowed of instantaneous work, many examples being shown. The rule for finding the magnification obtained by the combination was to divide the distance from the negative lens to the focussing screen by the focus of negative lens, and add one. The  $f$  value is found by multiplying the aperture by the magnification, and the equivalent focus by

multiplying the focal length of the positive lens by the magnification. He compared the results of taking a photograph with a short-focus lens and that taken with a tele-photo lens to the same size, the negative being much truer. The same result would be obtained by photographing with a single lens of the calculated focus of the tele-photo lens, but the rapidity was greater, as it did not require so much stopping down, and the extension of the camera would be much less. Mr. S. H. FRX, at the conclusion of the lecture, asked how the definition compared with an enlargement from a small negative to the same scale. Mr. MARRIAGE said theoretically the definition with a tele-photo should be as good as with an ordinary lens, and that practically the balance was very much in favour of the tele-photo lens. Mr. H. W. BENNETT thought the perspective shown in one or two slides was rather too slight to be altogether pleasing, which was admitted by the lecturer. Mr. MUMMEY said that it was perhaps because photographers were not accustomed to the perspective given by moderate lenses.

**West London Photographic Society.**—The Annual Meeting was held on the 13th inst., Mr. H. Selby (President) in the chair, and the Secretary's and Treasurer's report recorded a satisfactory year's working. The election of officers resulted as follows:—*President:* Mr. A. C. Beard. *Vice-Presidents:* Messrs. W. Collett, C. Dixon, A. Ebbs, and R. Horton. *Council:* Messrs. F. L. J. Barrow, G. F. Blackmore, M. W. Cockerell, G. Lamley, E. T. Lester, H. R. Proctor, L. Selby, and W. Taylor. *Hon. Treasurer:* Mr. A. E. Cockerell. *Hon. Secretary:* Mr. J. Brown, 28, Welte-road, Ravenscourt Park, W.

**Woolwich Photographic Society.**—The Seventh Annual Meeting took place on the 12th inst. The Society has had a most successful year. The balance in hand is 5*l.* 18*s.*, mostly profit from the 1899 Exhibition, at which no awards were offered. This enables the Society to become possessed of its own optical lantern, after paying off the syndicate of members who purchased the lantern, making some 9*l.* paid off during the present Hon. Secretary's term of office. Mr. W. H. Dawson was re-elected President, and Mr. F. W. Machen, 161, Griffin-road, Plumstead, Hon. Secretary. Next meeting on October 26. The Exhibition will be held on February 21, 22, 23, and 24, 1900.

**Liverpool Amateur Photographic Association.**—A demonstration was given on Thursday, October 12, by Mr. F. ANYON, who took as his subject

#### ENLARGING AND REDUCING BY ARTIFICIAL LIGHT.

With the aid of a diagram of the Club's new lantern, Mr. Anyon explained, in the most lucid manner, the management of the various parts in order to obtain the maximum of light. Dealing with the various methods of keeping the bromide paper flat during exposure, the lecturer advocated the wetting of the paper as giving the best results, and, in the matter of development, the use of amidol, which, in his hands, was everything to be desired. Mr. Anyon exposed a piece of bromide paper by means of the enlarging lantern, and the resulting print, on being passed round, was very much admired. At a subsequent stage Mr. Anyon showed the members how to reduce an over-exposed bromide print by means of a solution of iodine. The over-exposed print was first immersed in the iodine solution for a few minutes, and afterwards transferred to a solution of hyposulphite of soda, when it was found that, instead of a dark fogged print, the lecturer turned out a perfectly clear and beautifully graduated picture.

**Rochdale Photographic Society.**—The Annual Meeting of the Rochdale and District Photographic Society was held last week at the Temperance Club, St. Mary's Gate. Mr. G. Smith presided. In opening the meeting, the CHAIRMAN referred to the loss which the Society had suffered by the death of Mr. H. Bamford, their late Secretary. No one deserved more credit for the present sound position of that Society, and his place would be difficult to fill. The Secretary's report showed that the past year was the best the Society had experienced since its formation, though the rambles had not been so well attended as might have been desired. During the year the Society had purchased an enlarging lantern. This had been largely used by the members, and the work done by means of it was of a very creditable kind. There was a loss of 1*l.* 1*s.* 5*d.* on the Exhibition which the Society promoted recently; otherwise it proved highly successful. The financial statement showed a balance gain of 3*l.* 1*s.* 10*d.* on the last season's working. The following officers were re-elected:—*President:* Mr. J. A. Bright. *Vice-Presidents:* Colonel C. M. Roysds, M.P., Alderman J. B. Heape, J.P., the Rev. T. P. Spedding, Dr. W. Mills, and Messrs. R. M. Jones, C. Fairbank, and W. Ingham. *Committee:* Messrs. J. Grindrod, J. S. Johnson, R. Turner, F. Ashworth, J. Morrison, G. Smith, E. E. Ashworth, J. H. Whiteley, and T. Kerahaw. *Lanternists:* Messrs. W. Bray, E. Willman, J. Grindrod, and E. H. Seanor. *Treasurer:* Mr. W. Bamford. *Secretary:* Mr. E. H. Seanor. *Assistant-Secretary:* Mr. R. Whitehead. It was decided to hold another Exhibition this season, and the arrangements were left in the hands of the Committee.

#### FORTHCOMING EXHIBITIONS.

1899.

- October 20-24 ..... Croydon Camera Club. Hon. Secretary, W. H. Rogers, 106, Holmesdale-road, South Norwood.  
 „ 20-Nov. 4 ... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.  
 „ 20-Nov. 11... Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.  
 „ 22-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.  
 November 15-17 ..... Hackney Photographic Society. W. Selfe, 70, Paragon-road, Hackney, N.E.

November 20-25 ..... Longton and District Photographic Society. Thomas Mottershead, 43, Stafford-street, Longton, Staffordshire.

„ 27-Dec. 18 American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.

December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

„ 11-Jan. 1900 Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.

„ 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.

1900.

April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE ECLIPSE PHOTOGRAPHS AT THE ROYAL PHOTOGRAPHIC SOCIETY.

To the EDITORS.

GENTLEMEN,—Since writing you the letter which you have done me the honour of publishing in your issue of last week, I have seen a photograph of the sun passing behind a church spire, which leads me to think that the eclipse photograph on which I commented is possibly the result of a partial reversion. There are some things about it, however, which appear to me doubtful, but which could possibly meet their explanation if the original negatives were available for examination.

As the matter stands, the picture is an entire misrepresentation of the most essential part of the phenomena it purports to represent; it is one of those half truths which are far more difficult to deal with than an entire falsehood.—I am, yours, &c., J. F. TENNANT, Lieut.-General R.E.

11, Clifton-gardens, Maida Hill, W.

#### DRY MOUNTING.

To the EDITORS.

GENTLEMEN,—I am obliged for your reply to my query through Correspondence column of THE BRITISH JOURNAL OF PHOTOGRAPHY to-day's date, but regret you do not mention how to dry mounts. I think the prints probably have a mountant brushed over them while still on the ground glass, and when dry they will be removed from the glass, then moistened in some way, or perhaps the mounts are damped and then passed between rollers under pressure; what I would like to know is: (1) Usual method employed; (2) Constituents of mountant (starch alone is not sufficient); (3) Is there a roller mounting machine specially made for this work?

I think I have seen articles on dry mounting in the JOURNAL; could you oblige me with date without much inconvenience? I have taken the JOURNAL for about eight years, so no use going further back than 1890.—I am, yours, &c., G. FRANK.

Studio, 81, West-street, Gateshead, October 13, 1899.

[The method of dry mounting is given in a leading article in another column, but we should have thought that what we recommended last week would for this purpose, have been better than dry mounting. Any ordinary rolling press answers. None is made specially for the purpose.—ED.]

#### LANTERN SLIDES ON EXPOSURE.

To the EDITORS.

GENTLEMEN,—I am often asked by secretaries of photographic societies to read a paper on exposure or some kindred subject. My engagements do not permit me to spend much time on this work, and I have therefore prepared a new type-written paper, fully illustrated with lantern slides on exposure. This I shall be happy to send to secretaries as far as dates fit in, and Messrs. Field have provided examples of meters to accompany.—I am, yours, &c., ALFRED WATKINS.

Imperial Mills, Hereford, October 14, 1899.

## PORTRAITURE BY ARTIFICIAL LIGHT.

To the Editors.

GENTLEMEN,—You may recollect some time ago we asked your opinion in reference to a new principle of electric lighting, and, as you thought our idea patentable, we at once took out provisional protection, and are meantime engaged on the complete specification.

Your opinion, in the form of a critique of photographs we herewith submit to you, would be esteemed and be of value to us. They were all taken in the same evening, and the exposure for those of the children was a quarter of a second. There was no particular attempt at arrangement, as it was intended as really a test for our new method or application of the electric light.—We are, yours, &c., G. & W. MORGAN.

398, Union-street, Aberdeen, October 16, 1899.

[If we except here and there a slight heaviness of shadow, the specimens submitted to us are faultless. The lighting is soft and harmonious, the modelling excellent, and, on the whole, the work is of a high order of merit. An electric light allowing of an exposure so short as a quarter of a second, and yielding such results as those before us, is a distinct acquisition.—EDS.]

## PROFESSIONAL PHOTOGRAPHERS AND DEALERS' TERMS.

To the Editors.

GENTLEMEN,—In your reply to "Upperton," in your issue of October 6 you repeat what you have on several occasions informed similar inquirers "that, in order to secure dealers' terms, they must relinquish professional photography, and trade as dealers 'pure and simple.'"

I think a very fair question for your correspondent to ask would be, "How many dealers 'pure and simple' there are in business at the present time?"

Do not by far the greater proportion of them make a speciality of developing plates and films for their customers? No one can possibly blame them for this, for a man must be particularly "pure" and more than usually "simple" to allow work for which he has the time and capacity to pass his door.

At the same time, if manufacturers are to establish a rule of cast-iron inflexibility, which says to a professional photographer, "We cannot allow you a trade discount on films to reload the spools you develop for customers, or material of other kinds to sell to them, unless you relinquish this professional part of the business," why does not the same rule apply to a chemist, and refuse him trade terms so long as he receives payment for photographic work of a professional nature?

If a dealer may do "professional photography," why may not a professional photographer do "dealing?"

I firmly believe that in nine cases out of ten a photographer can employ his time better in developing the resources of his business than in selling packets of P.O.P.; but, if there is to be a strict line of separation drawn between the two businesses, a man ought not to be allowed to sit on the fence, but should be made to declare himself on one side or the other.—I am, yours, &c., W. T.

Newcastle-on-Tyne, October 12, 1899.

## MR. BLAND'S SUNBEAMS.

To the Editors.

GENTLEMEN,—Although it is now some years since the rotation of the earth was discovered, I am somewhat surprised that you and Mr. Bland have forgotten the fact. The amount of divergence of the beams shown in the photograph depends, of course, solely on the length of exposure.—I am, yours, &c., "SAMUEL."

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensues delay.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

## PHOTOGRAPH REGISTERED:—

W. J. J. Thompson, 2, Worcester-street, Kidderminster.—Photograph of old gates of St. Mary's and All Saints' Church, Kidderminster.

RECEIVED.—J. L. HODGSON. In our next.

COLLODION EMULSION.—T. RICKFORD says: "I shall feel greatly obliged if you can inform me what I require to prepare and mix a solution for the above used by photographers who photograph direct on the wood for engravers?"—Use the formula No. 1 for washed emulsion as given on page 1058 of the ALMANAC.

DENTED LENS MOUNT.—Y. L. As it is the cell in which the lens is burnished that is damaged by the fall, we should advise you to put it into the hands of a practical optician. If you attempt to do the needful yourself, you will probably crack the glasses.

ADDRESS WANTED.—T. PETERSON writes: "Will you kindly give me the address of the manufacturers, or the wholesale dealers, of the Leviathan Concentrated Colours?"—In reply: The manufacturers are, we believe, Messrs. Levi, Jones, & Co., Hoxton-square, N.

GRANULARITY IN ENLARGEMENT.—T. COHEN. The granularity in the enlargement is not in any way due to the paper upon which it is made, but to the original negative. The grain in that is apparently exceedingly coarse, and, as the enlargement is great— $1\frac{1}{2} \times 1\frac{1}{2}$  inches to  $12 \times 12$ —the coarseness is very conspicuous in the result.

RESTORING DAGUERRETYPES.—H. HALL says: "Would you kindly, through your valuable paper, tell me whether it is possible to restore a Daguerreotype the figures of which have all but faded away?"—The picture can be cleaned with a solution of cyanide of potassium; but, as our correspondent is evidently not familiar with the Daguerreotype process, he had better not attempt the work himself, but intrust it to some one who is. Many valuable Daguerreotypes have been quite ruined in inexperienced hands.

HYPONEGATIVES.—C. DRYCE says: "Herewith I send you a negative for your opinion as to the cause of its appearance. It, with others, was taken last year. Several, like the enclosed, have a scaley-like appearance. They were varnished with —'s varnish, but they have not all gone the same."—The trouble arises from the negatives not being properly washed before they were varnished, consequently the hypo has crystallised out. Apply the tongue to the "scales," and you will then have no doubt as to their composition.

STUDY OF LIGHT AND SHADE.—LIGHT AND SHADE asks: "1. Could you advise me as to the best plan an operator could go about so as to make a thorough study of light and shade? 2. Would you recommend attending classes where you are taught shading; would that be any help? and, also, 3. What books would you advise to study?"—1. Study the works of the best photographers, for example, the published portraits as seen in the shop windows, also the best works on photography. 2. Yes, certainly. 3. Inglis's work on posing and lighting, published by Dawbarn & Ward, Farringdon-avenue.

VALUE OF LENSES.—LENSES says: "I have in my possession a set of lenses similar to that mentioned in to-day's issue of your JOURNAL, p. 651, manufactured by R. & J. Beck, London. There are eight lenses, two 3 inches, two 4 inches, two 5 inches, and two 7 inches, with a brass diaphragm. As I wish to sell the set, would you kindly inform me in your Answers to Correspondents what it would be worth? It is in perfect condition, in case."—We should advise you to consult Messrs. Beck on the subject. We never undertake the valuation of apparatus. Probably, however, half the list price, whatever that may be.

A PATENT QUESTION.—FLASHLIGHT asks: "May I ask your valuable advice on the following? I have made an apparatus for catching the smoke generated on using flashlight powders; it is simple, extremely portable (taking up about as much room as two umbrellas when folded up), quickly adjusted, and quite effectual. Do you think it is of sufficient commercial value to warrant my completing a patent of some before putting on the market, or would you simply protect it and put on market at once? I should esteem it a great favour if you would advise me on the matter."—In reply: The best plan for our correspondent to pursue would be to provisionally protect his invention, and then submit it to some of the trade houses. He will then quickly discover its marketable value.

DAMAGED POSITIVE.—COUNTRY writes: "If you could kindly advise us about this picture, we should feel very much obliged. It has been sent to us for restoration, but all others that we have had like this had scratches at the back corresponding with the blurred spots, and it has only been a matter of black paint or velvet to put them right; but you will notice the coating at back of glass in this picture is not scratched. What, then, is the cause of the faded spots, and how can they be put right? As our customer values the picture highly, would it be safer for us to put it into the hands of one accustomed to the older processes, and could you favour us with the name and address of such?"—The picture has not faded; all that is the matter with it is, that the black varnish at the back has split from the glass. Remove the varnish, either by scraping or with benzole, and apply fresh. We should think you could do this yourselves. The picture has been returned to you.

A STUDIO QUESTION.—"BUSINESS" says: "I have erected a small studio in the garden of a house wherein I am a lodger, having the landlord's permission for the same. He himself helped me to build it. It has been there about eight months, and I have a very prosperous portrait trade in the town. It has just come to my knowledge that he has said that, in the event of his death (he is an old man), the house and studio would all be sold. Could you reassure me on the point, as I am very anxious, having laid out a good deal of cash upon it? The building is of wood, portable, bolted together in sections. It stands partly upon piles, partly upon bricks. I enclose a ground plan, that you may the better judge. These two piles are the only ones nailed to the floor of studio, all the other piles are quite disconnected. There is a little mortar between the bricks, but the studio is not joined to the bricks, it simply rests upon them."—As the studio appears to be a fixture, i.e., it is attached to the ground by being nailed to the piles which are in the ground, we suspect it will have to be sold with the house. However, it is a somewhat knotty point. Cannot you make some arrangement in the matter with the landlord while he lives? That would be your best plan.

## EX CATHEDRA.

On Thursday in last week there was a meeting in London of the Council of the Photographic Convention of the United Kingdom. The President (Mr. Crooke) occupied the chair, and he was supported by a good attendance of members. The Honorary Secretary and Treasurer (Mr. Bridge) reported that the accounts of the Gloucester meeting had been made up, and showed a profit. The principal business of the meeting was the election of an Honorary Secretary and Treasurer for the ensuing year, and the choice of the Council unanimously fell upon Mr. Bridge, who was cordially thanked for his valuable services to the Convention in the past.

\* \* \*

How richly Mr. Bridge deserved the thanks of the Council may be understood from the fact that after the Glasgow meeting the amount of Convention money in hand was only *11. 8s. 4d.*, whereas now, after all the expenses of the Gloucester gathering have been met, no less a sum than *63*l.* 6s. 8d.* is in hand—a profit over sixty pounds in one year's working of the Convention. This result, and the business like management of

Mr. Bridge which brought it about, needs no eulogy from us: nevertheless, we cannot refrain from congratulating the Honorary Secretary and Treasurer on the fact that a most enjoyable meeting of the Convention was also a great financial success, and we are sure that all Conventioners who read these lines will join us in these congratulations.

\* \* \*

On the previous evening the presence in town of the Convention President gave several members the opportunity of entertaining him at dinner at the Restaurant Friscoatl. Mr. Crooke had for his fellow guest Mr. W. J. Croall, of Edinburgh, the very able amateur photographer of animals, and the healths of both gentlemen were very cordially toasted. In addition to the guests of the evening there were present Mr. Thomas Bedding, Mr. E. J. Humphery, Mr. C. J. Emery, Mr. H. Vivian Hyde, Mr. E. J. Wall, Mr. W. E. Dunmore, Mr. H. Walter Barnett, Mr. James A. Sinclair, Mr. Seary, &c.

\* \* \*

We have received the report of the Examinations Department of the City and Guilds of London Institute for the session 1898–99, and we append some extracts from the remarks of the Examiners in Photography, Mr. C. H. Bothamley and Mr. J. D. Geddes. The first-named gentleman says: "Comparatively few candidates showed any real knowledge of even the elementary properties of lenses; 'depth of focus' was frequently confused with spherical aberration, and distortion of the image with roundness of field. On the other hand, the uses of the swing back were remarkably well known by several candidates. The routine of mercurial intensification was well known, but many of the candidates seemed to be unacquainted with probable sources of failure. Most of the candidates showed little knowledge of albumenised paper, and the discussion of the relative merits of this and gelatino-chloride paper was not, as a rule, well done. It would seem that more attention ought to be given to the photographic behaviour of mixtures of potassium bichromate and organic substances, especially having regard to the fact that the processes based thereon are of great practical importance. The candidates in both grades (Honours and Ordinary) appear

to be unacquainted, as a rule, with the relations between the general properties or qualities of emulsions and the results that they are capable of yielding, and this is another point to which more attention might be given with advantage." We give prominence to Mr. Bothamley's strictures on the weak points shown by the candidates at the last examination, in the hope that they may be noted by those photographers who intend being candidates at the next examination, and also by those upon whom devolves the duty of teaching or instructing them.

\* \* \*

THE Judge of the photo-mechanical process work, Mr. Geddes, reported as follows: "The answers to the questions indicate generally an advance in the knowledge of technical details of the processes dealt with. It is also noticeable that most of the students make a particular study of two, or at most three, of the subjects included in the syllabus, indicating, as might be expected, an industrial demand for specialists in one or other of the sections of photo-mechanical engraving and printing." Coming from a man of Mr. Geddes' long practical experience, the hint conveyed in the last two lines of his brief report is especially valuable to those contemplating taking up a branch of photography as a profession.

\* \* \*

WE learn from our American exchanges that Secco film is on the point of being introduced to the United States, photographic public. The *American Amateur Photographer* has the following remarks on the subject: "If we take it for granted that the Secco film is all that is claimed for it, the natural question is, What are our American plate-makers going to do about it? That nothing shall be done is simply out of the question; and equally so is the idea that the hundreds of thousands of prospective consumers of the film can get it only at the enhanced price incident to importation under protection. Our plate-makers have hitherto done well both for and by us, and, as we believe in respecting their vested interests, we should be sorry to see them superseded by a syndicate, or any other form of organization, in the handling of what we feel convinced will be the photographic film of the future. Although they are perfectly able to take care of themselves, it can do no harm to suggest that they should take time by the forelock, and make such an arrangement as to render that impossible. Just what that arrangement had better be is not for us to say or even suggest, but it should be such as will best conserve the interest of both parties—the makers, in not excluding any of them from producing the films; and the consumers, in getting them at a reasonable price."

\* \* \*

Our contemporary, we think, is needlessly alarmed in this matter. Whatever measure of success may attend Secco or any other kind of film, glass plates are scarcely likely to be "superseded," as the *American Amateur* seems to imagine is probable. Away back in the early eighties films were introduced in this country for the purpose of "superseding" glass plates, but the latter are now made much more largely than ever. The whole fact is, that in photography there is a plate public and a film public, and in proportion to the skill with which manufacturers cater for these publics so will success attend plates and films. To talk of films superseding plates or, indeed, *vice versa*, may be a pardonable exaggeration in a

prospectus, but a little reflection will show that neither state of things is at all likely.

\* \* \*

THE *National Druggist* recently gave some information respecting the fire-extinguishing qualities of ammonia, which may be of interest to those of our readers who still employ that alkali in development. "In one instance, where fire had originated, probably from spontaneous combustion, in a pile containing several tons of cotton-seed, and the interior of which was almost a solid body of live coal, a half gallon of ammonia completely smothered the fire. In another, which occurred in Savenay, France, the vapours of a tank containing fifty gallons of gasoline caught fire in the linen room of a laundry. The room was instantly a mass of living flames, but a gallon and a half of ammonia water thrown into it completely and almost immediately extinguished the fire. The ammonia was in a glass demijohn in an apothecary's shop next door to the laundry, and was thrown into the room by the druggist as an experiment. To use his own words in reporting the circumstance, 'The effect was instantaneous, torrents of black smoke rolled upward in place of flames, and in a moment every trace of fire was gone. So completely was the fire extinguished, that workmen were enabled to enter the room almost immediately, where they found the iron tank of gasoline intact.'"

\* \* \*

ON the subject of "A Third Eye," to which we made reference last week, a friend is good enough to send us the following note: "The pineal body—a small, reddish-grey, vascular body situated behind the third ventricle—is believed to be a vestigial sense organ, probably of sight. A rudimentary median eye (the pineal eye) actually occurs in certain lizards."

#### MOSER'S IMAGES.

THE paper communicated by Major-General Waterhouse to the Dover Meeting of the British Association, which we published in our issue of October 13, has, no doubt, interested many more of our readers than those who have had the opportunity of inspecting the specimens exhibited by General Waterhouse at the Royal Photographic Society's Exhibition. Silver—metallic silver—seems at first sight such an unlikely substance to be susceptible of any photo-chemical change that we may call attention to the many curious experiments made by Ludwig Moser nearly sixty years ago, on the lines of which General Waterhouse's experiments were made, but in which, nevertheless, we are inclined to think no explanation is to be found for the print-out image now obtained in a silver plate.

Moser's papers appeared in Poggendorff's *Annalen* in 1842, but a translation of them is to be found in Taylor's *Scientific Memoirs* for 1843. They record many curious facts observed in that obscure borderland, which still exists, between chemistry and physics. As recorded experiments they are most interesting, even though the theory which is entwined round them is at times fantastic. The author tries hard to make his experiments prove that light acts on all bodies, producing certain changes, the like of which are also produced by contact with other bodies and by the condensation of vapours.

Moser found that, by rubbing and pressing many surfaces, a latent image was impressed which could be rendered visible by exposure of the surfaces to a vapour, such as the breath or the vapour of mercury. Any one can make an illustrative experi-

ment in two minutes by writing on the back of a negative with any hard substance (or even the finger), such as the handle of a toothbrush, and breathing on the glass. The impression of the writing becomes visible, although before exposure to the breath not the faintest sign can be discerned. The development of the image can be repeated again and again even after the lapse of a considerable time.

Moser ascribed these results to "latent light," but the true explanation of them was not given until some years later.

It has long been known that all substances retain a thin film of air on their surfaces with such tenacity that very forcible means must be taken to detach it. Strange as this may sound, it is, nevertheless, true, and in many delicate physical measurements this adherent air has to be taken into account, and frequently the apparatus must be heated to redness to completely dissipate it. Now, this film of air is removed when, say, a stylus is pressed on to any surface, the pressure on a small area rising in such cases to something very great, and the surface acts differently in receiving a film of moisture or mercury according as it is or is not covered with an air film.

The production of images produced when a coin is laid on a freshly polished metal plate, from which, therefore, the film of air has been removed, is somewhat differently explained. In this case the metallic surface, when brought into contact with the coin, partially removes the air film from the latter and thus forms a latent image. Moser describes an experiment of this kind thus: "An engraved metallic plate was warmed and then held for about half a minute on a well-polished piece of silver foil or a clean mirror plate. When the plates were cold, they were breathed on and exhibited the above-mentioned appearance in a much more perfect manner; for not only were the outlines of the body visible but also the individual letters, &c., and all with the greatest distinctness."

But there are other facts recorded by him of which the conventional theory does not offer any satisfactory explanation. Thus the following: "A new plate of silver was cleaned and polished as well as possible. A surface with various excised characters was suspended over it without touching, and the whole was exposed to the sun for some hours and directed towards it; after the plate, which, of course, did not exhibit the least change, had been allowed to cool, it was held over mercury heated to about 60° Reaumur (170° Fahr.). A clear image of the screen was produced; those parts where the sunlight (which had been very weak) had acted had caused the deposition of a quantity of mercury."

This last experiment brings us more into line with General Waterhouse's work, with the great difference that in his case a visible image is produced on exposure to light. This is still less capable of explanation on the physical "air film" theory, and we await with interest the progress of the experimental work which General Waterhouse is undertaking; the results, by disclosing the action of light under the simplest possible conditions, may perhaps illuminate the more complex question of the photo-decomposition of the silver haloids.

**Technical Education.**—A great deal has been written during the last few years with regard to the technical education that the German lads receive in their schools, and that the rapid strides made by that nation in the arts and manufactures is greatly due to this part of the education; also there have been many comments on the lack of that branch of learning in this country. Now, however, we are giving more attention to the matter, and are establishing a

number of technical schools somewhat after the manner of our German cousins. It is with pleasure that we learn that, through the generosity of one of its governors, the Felstead Schools are now in possession of new chemical and physical laboratories, which have just been added to the school buildings, and which were opened one day last week. The new building contains a chemical laboratory, with benches for nearly thirty boys. In addition to this there are physical and electrical laboratories, as well as a commodious lecture room. With these acquisitions the Felstead Schools should turn out boys with a good education in technical matters, and able to compare well with those hailing from Germany.

**War Maps.**—Nothing, perhaps, more forcibly illustrates the progress that electricity and photography have made during the past few years than the present war in the Transvaal. The news of the attack on Glencoe was received here within two or three hours of its being made, and, although Glencoe is something like 7000 miles away, the War Office here was kept posted up, every hour or two, as to how the battle was progressing. Not only were Londoners able to read the details of engagement the next morning at their breakfast table, but they were also able to follow the movements of the troops and the enemy by skeleton maps by which the accounts were accompanied. These maps were all reproduced by means of photography. The maps were drawn to scale and reproduced photographically and line blocks made, each map having a scale in English miles at its margin, so that the reader could the better realise the distances from place to place. These blocks are all made, and got ready for setting up with the type, at a few hours' notice. But for photography such a thing would have been an impossibility.

**A New Observatory at Lincoln.**—The Lincolnshire County Committee have been offered, and have accepted, a valuable set of astronomical instruments by the executors of the late Canon Cross of Appleby, who took a great interest in astronomy. It is proposed by a committee who are promoting the scheme to erect an observatory in the keep of the old Castle at Lincoln, and to raise funds for its erection, and maintenance, by public subscription, and then to ask the Lincolnshire County Committee to take over the property as well as the valuable instruments in trust for the County. There should be no difficulty in raising the necessary amount, which need not be large, in the county alone, but, no doubt, it will be supplemented from outside sources. This country is not, by any means, over-stocked with astronomical observatories, and every one, however small, is useful in increasing the interests of astronomy. It might be worth the consideration of the Committee in this affair as to whether the observatory should not, at times, be open to the public at a small charge. Many who take an interest in astronomy have not the means of purchasing large and costly telescopes, but would gladly pay a small fee for the opportunity of seeing some of the heavenly bodies through one; and the fees would go to help to defray the cost of the maintenance of the building, &c. At one time there were some very fair telescopes, with up to six-inch object-glasses, to be seen in the streets of London on clear evenings, and they were well patronised. But we have not met with any of that class during the last few years.

**Nelson's Column.**—Not a few photographers, who had made up their minds to photograph the column with its decorations, on Saturday last, were much disappointed through the weather. A thick fog enveloped the square all day. Still, hand cameras were to be seen at various times, and some few enthusiastic amateurs made snap-shots, but the results could well be imagined by those who saw the weather at the time. We are told that attempts were to have been made at night to photograph the column with its electric-light decorations, but, of course, that was also futile, as the lamps could not be seen at any distance from it through the dense London fog that prevailed at night as well as all through the day.

**Guildhall Pictures.**—A week or two back we mentioned that the Art Gallery, at the Guildhall, was to be further enriched by the picture by Mr. A. C. Gow, R.A., depicting the memorable gathering on the steps of St. Paul's on June 22, 1897, with the Queen seated in her state carriage, attended by the Prince of Wales and several others of the Royal Family. The picture, which was in the last Exhibition of the Royal Academy, is the gift of Mr. Henry Clarke, a member of the Common Council, who takes great interest in the City Art Collection. The painting was unveiled by the Lord Mayor, on Friday last, in the presence of several of the aldermen and other City functionaries. One noteworthy feature in the presentation was the handing to the Lord Mayor the papers relating to the copyright in the work. In doing so, Mr. Clarke expressed the hope that any money derived from copies of the picture would be devoted to the purchase of further works of art for the Gallery. In this instance the City hold the copyright in the painting, as well as the picture itself. It is not always that the copyright is disposed of with the picture. A good photogravure of this work, we should say, would command a ready sale.

**Decoration of St. Paul's Cathedral.**—A considerable amount of correspondence has appeared in the press during the past year or so on the "decorations" going on in St. Paul's Cathedral, and as to their suitability in Wren's grand masterpiece. At the meeting of the Court of Common Council last week a letter from the Dean was read, asking for further financial help in the decoration of the building. In his letter the Dean said his Committee had already raised and expended 150,000*l.* on the work, and another 50,000*l.* was required to complete the decorations, and he would be thankful if the Court would repeat their previous liberal gift. As might have been expected, after what has been said in art circles as to the character of the decorations, and how much they were out of keeping with Wren's object in his design, the subject brought forth some very adverse criticisms amongst the Councillors. One of the gentlemen expressed himself in these terms: "The decorations, so called, not only gave a gaudy appearance to the edifice, but disfigured the beautiful design of its great architect." The opinion here expressed quite echoes those which have been so generally expressed by the public, and architects particularly, who consider the gaudy colouring as attempting to paint the lily. The beauty of St. Paul's is its fine architecture. However, Wren's masterpiece is not the only fine edifice that has been disfigured by modern "decorations and improvements." Certainly, in this instance, they will not add to the beauty of future photographs of the interior of the Cathedral. The Court of Common Council have, however, not yet decided to give this extra 50,000*l.* Two hundred thousand pounds is a large sum to expend in what many consider destroying the chief beauty of a fine Cathedral—its architecture.

#### FOREIGN NEWS AND NOTES.

**Toning Bromides.**—The Belgian photographic paper, *Helios*, gives the following collection of formulæ for obtaining prints of various colours upon bromide paper. After development, fixing, and careful washing, bleach the prints in the following bath:—

Nitrate of lead .....	2 parts.
Potassium ferridcyanide .....	3 "
Water .....	25 "

As this bath also acts as a reducer, do not leave the prints too long in it, unless they are over-developed.

For brown tones wash the bleached print, and immerse it in the following bath until it assumes the desired colour:—

Schlippe's salt .....	2 parts.
Ammonia, '880 .....	1 part.
Water .....	30 parts.

For yellow tones use—

Neutral chlorate of potash .....	1 part.
Water .....	25 parts.

For green, take a yellow-toned print and immerse it in

Perechloride of iron .....	1 part.
Water .....	10 parts.

For red tones, immerse a yellow-toned print in

Chloride of copper .....	1 part.
Water .....	10 parts.

Bartolozzi red prints may be prepared by bleaching a well-washed bromide print in a dilute bath of bichromate of potash, acidified with hydrochloric acid, and then immersing it in a bath of

Schlippe's salt .....	1 part.
Water .....	25 parts.

When the right tone is secured, wash the print until every trace of yellow disappears from the white.

**Colour Screens.**—Baron von Hübl recommends the following screens for three-colour work in the *Photographische Rundschau*. The screens are prepared by staining a well-fixed and washed bromide plate, and they are used in contact with the sensitive plates selected for making the negatives. The colours for which the negatives are made are purple, greenish-blue, and yellow. The negative for the yellow is made upon an ordinary bromide plate without a screen, but, as an allowance in focussing has to be made for the thickness of the screens, a plain glass plate is placed in front of the ordinary plate exposed for the yellow. For the red, use a plate sensitive to yellowish-green, and stain the screen with—

Water .....	100 c.c.
Alcohol .....	40 "
Echtgrünbläulich (1:200) .....	12 "
Naphthol yellow, S. L. (1:200) .....	40 "
Glacial acetic acid .....	3 "

After the plate has been very deeply stained in the above, rinse it in distilled water to which a little acetic acid has been added, and dry it in a place free from dust.

For the blue, a red sensitive plate (dipped cyanine) must be used in conjunction with a screen prepared by immersion in the following bath:—

Water .....	100 c.c.
Alcohol .....	20 "
Biebricher Scharlach (1:200) .....	20 "
Methyl orange (1:200) .....	5 "
Naphthol yellow, S. L. (1:200) .....	5 "
Glacial acetic acid .....	3 "

Rinse and dry, as in the case of the green screen.

**The Paris Exhibition.**—We read in *Progrès Typo-Litho* that the following tenders have been made for the right to print, and sell the catalogue of the Exhibition:—Danel, 357,000 francs; Hachette, 452,500 francs; Lemerrier, 463,000 francs. The amount is to be paid in three instalments.

**Light and Toning Salts.**—The *Photographische Chronik* refers to the fact that weak solutions of potassium chloro-platinite, as used for toning silver prints, are unstable, and precipitate the metal as platinum black. The action of light upon platinite chloride reduces it gradually to platinic monochloride, and a very dilute solution of chloride of gold is also affected by light and deposits gold. But the writer thinks organic substances may play an important part in this case. Sulphocyanide of gold also decomposes and deposits a yellow substance of unknown chemical composition. As the solution was stored in a brown bottle, it is difficult to imagine what action light could have exerted upon it.

**Glass for Vacuum Tubes.**—In the *Archiv für Wissenschaftliche Photographie* we read that Dr. Schott has classified the various oxides and acids used in the manufacture of glass in the following order of capacity for transmission of X rays:  $Li_2CO_3$ ,  $B_2O_3$ ,  $Na_2CO_3$ ,  $MgO$ ,  $Al_2O_3$ ,  $SiO_2$ ,  $K_2CO_3$ ,  $CaO$ ,  $Mn_2O_3$ ,  $As_2O_3$ ,  $BaCO_3$ ,  $PbO$ . Taking this into consideration, as well as other essential properties, the new glass for manufacture of tubes is composed of sodium 10 per cent., boracic acid 30 per cent., alumina 20 per cent., arsenic acid 0.4 per cent., silicic acid 39.6 per cent. This glass has a much lower coefficient of expansion than platinum, and it therefore follows that, if straight, polished platinum wire is fused into it, a capillary space of annular section is formed in the process of cooling. This can be filled with a non-volatile oil by suction, and perfect vacuum is thus secured. Gundlach has made durable tubes in this manner, but it has been found that the relative position of the cathode and platinum foil have much more im-

portant influence than the difference of transmission of the old and the new glass. It is probable that the use of the new glass will, for this reason, be confined to the manufacture of vessels for the examination of substances by the Röntgen rays.

**The Gum-bichromate Process.**—In the *Photographische Chronik* it is suggested that coloured resins may be used with advantage to replace the ordinary dry colours and red acaroid, asphalt, turmeric, dragon's blood, guaiacum, &c., and the following formulæ are suggested:—

No. 1.	
Distilled water .....	100 parts.
Gum arabic .....	25 "
White candy sugar .....	2-3 "
Ammonium bichromate .....	5 "
Ammonia, sp. gr. '91 .....	5-3 "

No. 2.	
Resin, in powder .....	5-10 parts.
Absolute alcohol .....	15-20 "

For use, No. 1 is filtered and mixed with No. 2, which will be quite pasty, and then the mixture should be coated once or twice on well-sized drawing-paper. The first coating must be quite dry before the second is applied. Over-printed proofs should be developed with hot water. With a thin coating it is stated the results are more artistic, and with a thick coating the prints have more the appearance of ordinary carbon prints.

**The Reflection of Light.**—The *Deutsche Photographen Zeitung* publishes the following table of the amount of light reflected by the various surfaces and colours, the incident light being considered as unity, and the D spectral line being taken as the maximum visual luminosity:—

Black velvet .....	0.004
" cloth .....	0.012
" paper .....	0.045
Dark blue .....	0.065
Damp dark earth .....	0.079
Dark green .....	0.101
Bright red .....	0.162
The moon .....	0.170
Dark yellow .....	0.200
White stone .....	0.237
Bright blue .....	0.300
" yellow .....	0.400
" green .....	0.465
" orange .....	0.548
Photographic paper (white) .....	0.700
Snow .....	0.783
Mirrors .....	0.923

As the maximum sensitiveness of an ordinary plate lies about  $F \frac{1}{3}$  G, the colour of an object should be considered from this point of view. To obtain the same density for the various colours on an ordinary plate as that given by blue or white light, the following relative exposures must be given:—

Violet, about .....	2
Green " .....	4
Greenish-yellow, about .....	30
Yellow .....	36
Orange .....	120
Red .....	1600

#### PHOTO-SCULPTURE AND THE CINEMATOGRAPH.

THE *Photographisches Wochenblatt* announces a novel application of the cinematograph, and, if the results can be readily obtained equal in quality to the specimen of which our contemporary publishes a print, we may shortly see a new style of portraiture in fashion. A studio has been opened in Berlin for the production of photographic bas-reliefs by the Selke Photo-sculpture process. These portraits are not mere photographs stamped in relief, but consist of a series of silhouettes of successive planes in profile pasted over each other. The sitter is placed in front of a suitable background, and by means of a zonal mask and a series of arc lamps a shadow is cast upon the sitter from all sides. By advancing the shadow, and at the same time taking a series of forty to fifty silhouettes with the cinematograph, the requisite negatives may be taken in three to five seconds.

The first gives the entire profile. The second is rather smaller, owing to the advancing shadow. The last merely represents the most prominent parts of the figure, say the cheek bone, the hair over the temple, and the tip of the ear. These negatives are enlarged upon bromide paper to a suitable size, cut out and pasted one over the other. The edges are smoothed out with wax or some other plastic material, and a mould made from which any number of terra-cotta or plaster casts may be taken.

#### ACETYLENE FOR PHOTO-MICROGRAPHY.

DR. NEUBAUSS points out that, whilst limelight is the ideal artificial light for photo-micrography, its expense and trouble is against its general adoption. The arc lamp cannot be used because the point of light shifts so. The incandescent gas is used, but the image of the mantle itself is frequently troublesome. He therefore suggests that the acetylene cycle lamp should be used, and a lamp of this kind which gives a flame of about three-quarters of an inch high will give excellent results with exposures about half as long again as for the incandescent gas. One great advantage is that the flame is much smaller than the incandescent mantle. The reflector of the lamp should be removed; a plane reflector, preferably of white metal, should be used instead. It frequently happens that the generator gets hot. In cycling this is, of course, obviated by the cooling action of the air; for photo-micrography this trouble may be got over by placing the generator in a vessel of water.

#### NEGATIVE DODGING.

A few years ago photographers were contented with their negatives after everything that would improve them had been done by means of chemicals. Since then things have altered, and they have now learned to consider the negative as only a means to an end, and that end is to get as perfect a print from it as possible. To do this "dodging" is resorted to after all chemical means of improvement have been exhausted. By "dodging" is meant the use of certain tools, mentioned hereafter, in such a way that they obliterate or tone down objectionable parts, and introduce others that will improve.

Discretion, of course, must be used, as it can easily be overdone in the same way as retouching. By the way, retouching of portraits comes under the head of "dodging," but I do not propose to describe it, it being more or less familiar to every one.

The tools required are very simple and inexpensive, and need but little skill in their use. They are: one bottle of retouching medium, one ditto vaseline, tube of ivory black (oil colours), one ditto gamboge (water colour), three brushes—one camel's-hair (fine), one hog's-hair (medium), and a No. 1 sable—a packet of white tissue paper, some fine emery powder and paper, two retouching pencils (Nos. 3 and 4), a little black-lead powder (waste from retouching leads), one paper stump, a penknife with a very sharp point, and a retouching needle. The latter can be made at home by boring a small hole in a penholder, and fixing the eye portion of a fine needle tightly in it. The point may then be ground upon a stone to sharpen it. A retouching desk will be indispensable.

The negative must first of all be prepared by removing all grit from the glass slide, and neatly pasting a sheet of the tissue paper over, being careful not to have any creases or surplus of paste on it. The tissue paper must be of the finest quality, of an even transparency, and free from any mottling or flaws. Tracing paper may be used instead, providing it is not of a yellow colour.

If preferred, matt varnish can be applied in place of the tissue paper, but it will be found that the latter is the easiest to use. In applying the former, hold the negative in the left hand by the edges with the thumb and first finger, so that the glass side is upwards and in a horizontal position. Then take the bottle of varnish and pour a small pool in the middle, tilt till evenly distributed, taking care not to allow it to run over the edges on to the film side. Lay flat to dry, which will only take a few minutes. Slightly damp a piece of linen (free from lint) with the retouching medium, and gently rub with a circular motion all over the film side.

The retouching pencils are prepared by rubbing up to a very fine point on the emery paper. Save the lead dust, for it will be useful.

For an example of the method of "dodging" we will suppose we have a thin landscape negative, with weak detail in the shadows and faint clouds in a fairly dense sky. Having prepared the negative with tissue paper and medium, place it on the retouching desk with another piece of tissue over the film side, and then trace the outline of the horizon by means of one of the pencils. Remove the tissue and cut away the sky portion. It may then be pasted on top of the view portion of the negative, on the glass side, seeing that it registers exactly, so that there are two thicknesses over that part and only one over the sky.

Commence by brightening the detail in the shadows, on the film side with the retouching pencil No. 3. Hold it in the right hand in much the same way as a pen is held, only very lightly, and make small, fine strokes, laying them close up against each other, never allowing them to

overlap one another. If this does not make the detail sufficiently strong, go over it again, making the strokes in a different direction so that they cross the others in a similar manner to fine cross hatching. Too much pressure must not be put on the pencil or it will remove the medium and scratch the gelatine.

The high lights may now be brightened up. This is best done on the tissue-paper side. Squeeze a little of the gamboge out on to a clean glass, add some water, and well mix with the camel's-hair brush. Do not make it too thick. Its right consistency is when it is transparent. Load the brush with it (not too full, or it will run), and apply to the brightest high lights, such as whitewashed houses, the glitter on water, bright patches of roadway, &c., taking care that the colour does not go beyond the outline. Where the high lights are to be perfectly white, the colour must be used thicker, and, when they only require a slight brightening, it may be applied more thinly.

At this stage a rough print ought to be taken to see how the work is progressing.

It is surprising what beautiful results can be obtained by simply introducing a little atmosphere.

If it is desired, it may be made by putting a wash of gamboge over the portion of tissue that covers the distant parts of the view.

The clouds in the sky should now be improved to make them printable.

First deepen the density of their high lights by loading the paper stump with black lead, and rubbing it on the tissue directly over them. Turn the negative over, and reduce the shadow portions, to still further increase the contrasts. This is done by covering the rounded portion of a penholder with chamois leather, and dipping in the emery powder. It is then gently rubbed on the shadows from left to right, taking the precaution to see that the reduction is evenly done. Rubbing too hard will scratch the film and spoil it.

Harshness of contrast is another defect which is very prevalent in negatives, especially in those depicting interior scenes. In "dodging" these, they should be prepared in a similar manner to the above, with retouching medium and tissue paper. With the stump and black-lead powder go over all the deep shadows, putting an even coat of black on the tissue side, of course not working over the edge on to the high lights, or it will deepen the contrast instead of modifying it. If the contrast is very strong, a wash of gamboge can be used instead of the black lead. The detail in the shadows may be touched up with the pencil, but the high lights must be left severely alone. The contrast may still further be harmonised by dipping the hog's-hair brush in the vaseline and painting over the high lights on the tissue-paper side. This makes the paper transparent in those parts.

Dirty skies, that is, skies that print muddy or uneven, are another source of trouble to the photographer.

Practically the only method of improving these is to block them out. By blocking out is meant to so cover the sky up that it prints perfectly white. No doubt the best method is to paint it out by means of opaque paint. Squeeze a little of the ivory black out on to a piece of glass, and add a little turpentine to make it semi-liquid. Then take the fine sable brush, dip in it, and gently paint round the edge of the sky close up against the horizon. Having gone all along the outline, fill in the rest with the hog's-hair brush.

Every spot ought to be covered, so that it is perfectly opaque when viewed by transmitted light. The greatest care must be taken not to paint over the edge on to any portion of the view.

Some ladies are continually exercising their minds with the problem of how to reduce the size of their waist.

It may be done by means of photography; at least, it can be made to look smaller than it really is if the sitter is taken against a white background and a portion of the waist each side painted out. First of all, two lines must be drawn, one each end, by means of the pencil. They must be parallel to the outside of the waist. The amount to cut off will, of course, depend upon the size of the figure. If a cabinet, about one-twentieth of an inch each side will generally be found sufficient. The sable brush and black paint can then be taken and painted on the background and waist till it reaches the line. If skilfully done, detection will be impossible.

The beautiful effect of snow falling is very hard to render in a photograph by natural means, but it can easily be "dodged" in. Of course, the surroundings must be as natural as possible. For instance, it would be impossible to get it to look natural on a summer landscape. It matters little whether the "snow" is placed on the glass or film side of the negative. It is done with the small sable brush and black paint. The spots must be made small, not all of a uniform size, and should be placed irregularly over the negative.

Portraits, if brilliantly lighted, may be made to look exactly like statuary by cutting out the background of the negative so that it prints black.

Place it on the retouching desk and take the penknife, hold it upright, and gently but firmly cut round the edge. It must be done very gently, or the knife will cut over the edge. Having gone round the outline, hold the knife on a slant, so that the handle points over the right shoulder, then draw it along about one-sixteenth of an inch from the outline cut, and it will peel off the gelatine in strips. The whole of the background must be done in this way, first making an incision in the

film and then peeling. It is well to practise this on old negatives first before attempting on a valuable one, as the slightest slip may ruin it.

Sometimes the movement of a figure in the foreground will spoil an otherwise good negative. To obliterate this, use the retouching pencil on the light portions to make them of the same density as the surrounding parts, then take the retouching needle and lightly cross hatch over the dense parts till they are reduced to the same depth as the rest. If carefully done, close inspection will fail to reveal that there had been any figure there.

The needle will also be found a useful appliance for toning down high lights of too great a density, which are too small to be reduced by means of emery powder.

Portraits taken out of doors usually have objectionable backgrounds. These can so be "dodged" on the negative that they print lightly, throwing the figure into relief and giving very pleasing results.

The best method is to cover the back of the negative over with tissue paper, and paint all over the part covering the background with a wash of gamboge, of course taking care not to put any over the figure.

If you have a very thin landscape negative which gives a dark print, do not throw it away, but paint a spot on the glass side of its sky with ivory black, and have one or more zigzag strokes coming from it. This will give the effect of lightning, and makes a picture of an otherwise worthless negative.

Many other improvements can be effected with the above simple appliances.

OSBORN THORNBERT.

## THE OPTICAL LANTERN AS AN EDUCATIVE MEDIUM.

[Transactions of the Edinburgh Photographic Society.]

TO-NIGHT I purpose saying a few words to you upon the magic or optical lantern. It may be that at certain stages I shall prove rather technical in my expressions; should this be so, you will please bear with me. It will be my endeavour to make the evening as interesting as possible. As my time is limited, I need not go much into the details of history; suffice it to say that, according to some authorities, the optical lantern dates as far back as 1260 A.D., but more definite information dates from the middle of the seventeenth century.

Athanasius Kircher, a Jesuit priest, wrote a book entitled *The Great Art of Light and Shadow*, which was published at Rome in 1646. In this book was the illustration of a lantern, which I shall show you on the screen.

It was not until 1789, when Aimé Argand invented the now well-known "Argand" burner, that any distinct improvement was effected in the lantern, the drawback having been the lack of a strong enough source of light. During recent years improvements have made rapid strides. Owing to the demand by Educational Departments, a great impetus has been given to the quality, efficiency, and cheapness of these instruments. From a mere nursery toy the magic or optical lantern has become an indispensable piece of apparatus in the schoolroom and lecture-hall.

I shall now describe a lantern, explain the use of the different parts and the relation they bear one to the other, and then indicate some of the many uses to which it may be employed.

A lantern consists essentially of:—

- (1) A source of light or radiant.
- (2) A condenser to collect as much of the light as possible and illuminate the object or slide to be exhibited.
- (3) An objective or front lens to project the light on to the screen.
- (4) A box or body so arranged that the adjustment of one or all of the parts can be readily effected, and, when adjusted, to allow of them being clamped firmly in position. A further use of the box or body is to prevent rays of light from leaking into the lecture hall.

*Sources of Light or Radiants.*—These may be the different forms of oil lamps, incandescent gas-burners, acetylene-burners, etho-oxygen or oxy-hydrogen, or electric light.

The most popular are the paraffin oil lamp and the oxyhydrogen lime-light; these two we shall consider more fully to-night. The heavy oils, such as sperm, colza, and sweet oils, are now used mostly in toy lanterns, the form of lamp to burn these being cheaply made. The best form of paraffin oil lamp is one having three or four wicks, and which are placed edge on to the condenser. Each wick having a separate turner, a very good light can be obtained. The chimney is adjustable to height, and is thus able to compensate for any variation in the density of the oil.

The oxyhydrogen or oxy-coal gas lime light is the most popular of all lights. It is exceedingly brilliant in its effect, comparatively cheap to work, clean to use, and the various parts of the apparatus are rapidly put together.

Oxygen and hydrogen, or oxygen and coal gas, when mixed and ignited in a special burner, produce a flame having an intense heat, which in turn raises an incombustible substance to an incandescent condition. The incombustible substance mostly used at this time is a selected sample of Nottingham or Irish lime. The lime is turned into cylinders with a hole through the length to support it on a pin in front of the O+H flame.

The coal gas—because, generally speaking, coal gas, owing to its convenience, is used instead of pure hydrogen—is first of all ignited, and the

lime cylinder so placed that it very soon becomes well heated in the flame. The purpose of gently heating the lime at first is to drive off all the moisture, otherwise the piece of lime would split. Gradually the oxygen is turned on until the proper mixture has been effected. The result is an intensely brilliant light.

There are different kinds of lime burners. The principal ones are: Oxycalcium or spirit jet, blow-through burner, mixing burner, ether saturator.

I may just remark in passing that the electric light is now being used as a radiant in many large institutions where this form of light is employed for general illuminating purposes, but only there; it is not transportable like the other kinds of radiants. Doubtless, when we have it more in our houses, it will become the light for the lantern.

Having now described the kinds of radiants or sources of light, I should like to show you briefly some of the properties of oxygen, for it, combined with coal gas and lime, is the radiant I shall be using to-night with the lantern we have before us.

Until comparatively recently, oxygen for lantern work was made by heating potassium chlorate with manganese dioxide, sand, or some other practically inert substance. If potassium chlorate is heated by itself, it requires a temperature sufficient to melt it before it yields up its oxygen. Should the melted chlorate be spilt and come in contact with any flame, there is a danger of fire; when mixed or diluted, one might say, with manganese dioxide or sand, and heated, the gas comes off at a much lower temperature, and the flow of gas is much more under control.

All chemical compounds are composed of simple elements. For brevity of expression, these elements are known for the most part by the initial letter of the name. For instance, potassium chlorate, of which I am speaking, is expressed by  $\text{KClO}_3$ .

Potassium (Kalium) .....	K=1 part.
Chlorine .....	Cl=1 "
Oxygen .....	O=3 parts.

If, then,  $\text{KClO}_3$  is heated moderately in a retort with  $\text{MnO}_2$ , it yields up its O, the process being—

$\text{K}$	}	$\text{KCl}$ = potassium chloride left in retort as residue.
$\text{Cl}$		
$\text{O}_3$	}	O. Given off as gas.
$\text{MnO}$		

The gas so driven off is collected in bags or gas-holders, and is kept there stored for use. When heating the mixture, a certain amount of  $\text{MnO}_2$  dust, free Cl together with KCl as a fine smoke, come over. These impurities would soon destroy the rubber storage bag; but, as the gas leaves the retort, it is passed through water, and these impurities are got rid of.

When required for use, the gas is expressed by means of iron or lead weights placed on a frame into which the bag is placed. The flow of gas is regulated by means of a stop-cock.

This process of producing and storing O is still carried on, especially where small quantities are required, but in a comparatively short time will be quite superseded by the cylinders of O, which are being extensively supplied to all who require them, and that at a very cheap rate.

The O in this case is practically taken from the air, so that there is no lack of supply, and consequently the cost of material is very low indeed.

Barium dioxide ( $\text{BaO}_2$ ), when raised to a full red heat, yields up one of its atoms of O, leaving BaO as a residue. This O, driven off, is collected in a tank, and is then ready to be pumped into cylinders, of which I shall speak presently. The BaO is allowed to cool, and, in the process of cooling, it absorbs an atom of O from the air. The BaO again becomes  $\text{BaO}_2$ ; this  $\text{BaO}_2$  is again heated to obtain the O, and so on. Whenever a sufficient supply is received into the gas-holder, the gas is pumped by machinery into steel bottles or cylinders, such as I now show you. This cylinder, when full, contains 40 cubic feet of O—equal to a column 40 feet high by 1 foot square at the end. The actual pressure within this cylinder is 1800 lbs. per square inch, or 120 atmospheres. This is an enormous pressure. As a safeguard, however, every cylinder is tested up to twice this amount.

Having, in a somewhat slipshod fashion, described the processes of obtaining oxygen, I shall now demonstrate to you a few of its properties.

First, then, it is non-inflammable. I apply a light to it, and it won't burn, do what I will.

If common air is mixed with it, no explosive compound is formed (in fact, it is O diluted principally with N that forms ordinary air). Not so if air and coal gas or O and coal gas are mixed in certain proportions and ignited, an explosion would be the inevitable result.

Oxygen is necessary for life.

You will all have read about ships' officers having been found dead in their cabins on the morning after a cold night. To make themselves cosy, these officers shut the doors, heaped up the charcoal fire, and went to sleep. In a short time the O was, between the fire and the reathing, all exhausted, and consequently the officers could not live.

I shall demonstrate this to you very simply.

Take a jar with common air, and, with a small candle, gradually burn out the O. In a short time the candle will go out for lack of O. The candle, when burning, requires O, and, in burning, a new gas is formed ( $\text{CO}$ ), which does not support life.

O inhaled, CO exhaled, by human beings.

It may interest you to know that O is now being extensively used by the medical profession in cases of lung disease. I have just demonstrated to you that it is most necessary for life, and, with this in view, the medical men use it undiluted in specially urgent cases. It is known to prolong life considerably, but I cannot authoritatively state that life has been saved by its application. Of course, in the early stages of a deadly disease, its application might prove of more lasting benefit.

O is a supporter of combustion. The experiments to demonstrate this are very remarkable.

I shall now arrange to show you in use one of the burners previously shown to you, and demonstrate the intense heat obtained by the properly adjusted quantities of oxygen and coal gas. In the flame of the mixed gases you can burn a steel knitting needle as easily as one can burn a straw. It is with this intensely hot flame that the lime already shown to you is made to emit the brilliant light for use in the lantern (the lime is made incandescent).

Oxygen is the active element in all bleaching operations. Fresh country air (containing a full percentage of oxygen) with water goes much further in the way of producing spotlessly white linen than the much-adulterated air of our over-crowded cities.

Hydrogen peroxide, the substance with which one can make golden hair out of brown, black, or grey locks, is largely composed of oxygen; this, when applied to the hair, bleaches it (fair hair is bleached hair).

A fifth of the atmosphere consists of oxygen.

Eight-ninths of water

About half of the mineral kingdom consists of oxygen.

"	"	plant	"	"	"
"	"	animal	"	"	"

In fact, half of the entire globe consists of oxygen.

The condenser will now occupy our attention for a few minutes. The condenser consists of one or more lenses, and of varying size, according to the quality of the lantern. Its use is to collect or concentrate as many of the rays of light as possible, so that the object to be projected on the screen will be equally and brilliantly lighted. There are what are termed simple condensers and compound condensers. The former consists of one lens, while the latter may be two or more lenses. The various styles of condensers I have roughly traced on a glass plate. This slide I shall also show you on the screen. The condensers in the better qualities of lanterns are from four to five inches in diameter.

The objective or projecting lens is the lens one sees at the extreme front of the lantern, and its use is to project the rays of light on to the screen.

According to the distance between the lantern and the screen the size of disc or picture is determined. The nearer the lantern is to the screen the more brilliant is the picture, but the size is small. The further away the size is larger, but the illumination is less brilliant. Of course, one fixes on the size of disc to suit the nature of the hall and number in the audience.

Coming to the containing box, or body of the lantern. This may be made entirely of metal, or of wood metal lined. For oil, metal is sufficient, but, where O+H is used, it is desirable to use wood, metal-lined. The intense heat from the incandescent lime makes a metal body uncomfortably hot, unless it is constructed on a larger scale than those constructed of wood. Such lanterns are made, and they are in every way satisfactory. Wood, being a non-conductor of heat, admits of a more portable apparatus.

Having now shown you the different parts of a lantern, the adjustment of these will next have our attention. This had better be shown in the lantern itself.

Two things are wanted in a lantern after all the parts are put together—(1) the centering and focussing of the light, and (2) the centering and focussing of the picture. This I shall now demonstrate to you.

It will be quite evident to you that the O+H light is a pure white one. When delicate tints of colour have to be examined at night in paper-works, dye-works, &c., this quality of light is in demand. With it the most delicate tints can be determined. When deciding tints, we can be easily misled if the conditions of light are not favourable.

An important item in a lantern outfit is the screen. The two special features of a good screen are opacity and whiteness. A paper-faced screen is better than a linen one, but the latter is more popular because of its portability.

Having described to you how a lantern is constructed and how to project a picture on the screen, I shall now indicate a few of the uses of a lantern.

We all know with what delight children hail the advent of a magic lantern. The annual Sabbath school treat is quite a failure to them without the pictures on the screen. The old folks, too, enjoy themselves quite as well on such occasions, although, perhaps, they are not so demonstrative as the young folks. In a measure, the enjoyment of the old folks is twofold—the viewing of the ever-varying effects on the screen, combined with the pleasure of seeing the children enjoying themselves. Of course, the quality, style, and subject vary exceedingly, from coarse gelatine transfers to beautifully hand-painted slides, or very fine photographic transparencies. Subjects, from the most awe-inspiring and pathetic to the extremely ridiculous are thrown on the screen, but all these the children are pleased to receive in turn.

For teaching purposes the lantern is making great headway, both in projecting pictures and the shadows of actual apparatus on the screen. Many of our day and night schools use them regularly, and with distinctly marked effect. While forming a means of attraction to undecided or indifferent scholars, it instils into the minds of others new ideas for some noble work. Teaching in the dark was at first objected to on account of anticipated misbehaviour of the scholars, but miracle is the exception, there is too much concentration of thought on the illustrations to admit of frivolity.

Geography can be taught and illustrated by means of maps, on which can be pointed out the cities, rivers, lakes, mountains, &c., requiring special notice. Photographic slides of towns, showing the styles of architecture, the features and dress of the inhabitants, and modes of conveyance, the size of the rivers, with all sorts of craft upon the waters. The geology and botany of a country can be illustrated in the same way. In fact, a subject need only be mentioned, and the lantern will at once do its share of the work.

History can be illustrated by means of photographs from pictures of all kinds of celebrities—statesmen, soldiers, sailors, men of science, and champions of religions; while battlefields, birthplaces, and the many ruins of bygone ages are shown on the screen in the same way.

You can readily understand that the teacher is now appealing to another sense other than that of hearing, viz., sight, and this, one can understand, gives the student of to-day a twofold advantage in his educational course.

Sometimes a large diagram is wanted for a small illustration in a book. With a lantern to help, nothing is simpler. Photograph the illustration, and put the negative, or a transparency therefrom, in the lantern. Project the illustration on to a suitable piece of paper, and then merely trace down the lines with suitable pencils or chalks.

Business men employ the lantern for advertising purposes—projecting illustrations of their specialities on suitable screens in prominent places. For instance, I have prepared some slides of lace which I shall now show you on the screen. I cannot tell the ladies of the audience whether these are up-to-date specimens or not, but they will serve my purpose.

Photographers make use of the lantern for producing photographic enlargements.

There is really no man of science but directly or indirectly makes use of, or can make use of, the optical lantern. The astronomer sets himself the task of being a combined observer, photographer, and lanternist—a comprehensive combination, you will admit.

The anatomist, geologist, physiologist, pathologist, and chemist are appealing daily to the lantern for assistance. Direct sections of the brain are prepared and thrown on the screen for the instruction of the student of physiology, while a combination of camera and microscope supply the botanist and pathologist with invaluable material for their courses of lectures.

It is a most desirable thing that lanternists in turn should be able to photograph. You can well understand what additional power is given to any one when he photographs many of the objects, places, and people he sees during the holiday time. With a store of good negatives he can produce for the winter numerous interesting illustrations for the edification and pleasure of his circle of friends. Or, again, some interesting subject presents itself in a book, it is quite a simple matter to photograph it and add it to the gradually accumulating pile of slides.

In passing, I may say that religious subjects are being taught successfully with the lantern. Ministers are now giving illustrated sermons, and the idea to me seems to be a very happy one.

Apart from the medium of photography, one can make what are termed diagrammatic lantern slides. By means of a piece of ground glass and a pencil one can trace many a book illustration in a manner similar to that employed in a child's drawing slate, the surface of the ground glass being the finest obtainable. After the tracing is complete the glass is coated with varnish, which renders it perfectly transparent; the pencil lines are now protected, and the granular surface of the glass has disappeared. This is mounted in the ordinary way, and the slide is complete. There is no objection, of course, to a freehand sketch being made on the glass, and then finished off in the same way. Further, pieces of glass are coated with a substance which admits of its being scratched off without leaving a ragged edge. Brown or blue are the colours usually employed; the latter colour is selected by teachers of physical geography, for with it they can readily produce a map of the heavens quite natural in effect.

Until now I have spoken of the lantern in connexion with ordinary slides. With your leave we shall go off the beaten track a little and see what other uses we can make of it.

The vertical front, as a modified adjustment of the parts of a lantern is termed, is used by science teachers for many purposes. Experiments that cannot well be shown to a large audience by ordinary means are projected most effectively on the screen by this arrangement.

Without describing it in detail it will suffice to say:—

- (1) That the condenser is split.
- (2) That a mirror is placed at an angle of 45° between the two halves of the condenser (one half of the condenser being at right angles to the other).
- (3) Readjustment of the radiant.
- (4) Table for displaying apparatus.

#### (5) Focussing and directing on screen with a mirror or prism.

The object of this vertical front is to project apparatus lying horizontally, so that they may be viewed in a vertical position. For example:—

The teacher on magnetism and electricity finds this most useful. Wishing to show what are termed magnetic curves, he proceeds thus:—On the glass table he places a small horseshoe magnet, and sprinkles near the poles some fine iron filings by means of a pepper box, and taps the table gently, observe curves. Further, the magnetic needle and its relation to the electric telegraph. The principle which I shall next show you bears an important part in telegraphy. It was discovered by Oersted in 1820 that, when a current of electricity was passed over a magnetised needle, the needle was deflected or caused to move out of its normal position of N and S. Here I have a needle pointing N and S. Observe, when I bring the wires from a battery near to it, there is a sense of uneasiness; when close, the needle deflects, + and —. What I have just shown to you demonstrates the fundamental principle of the electric telegraph. Supposing I wanted to write on the screen any problem in arithmetic or a chemical formula, it can be easily done by this same arrangement, KClO<sub>3</sub>, &c.

A fitting to an optical lantern is the erecting prism. Its function is to project objects in their natural position on the screen—not inverted as they would otherwise be. When I wish to show, say, the separation of the gold leaves of an electroscope, the action of an acid on chips of marble, the precipitation of a chemical, a fish swimming, and, in short, when I wish to project the shadow of any small object on the screen, I employ the erecting prism.

The microscope is used with much effect in connexion with the lantern.  
A. H. BAIRD, F.R.P.S.

#### LANDSCAPES AND CLOUDS.

MR. CADETT's paper on this subject, read before the Camera Club last week, was listened to by a large audience with great interest, for it touches upon a point which is of the greatest importance to the aspiring amateur. It need hardly be demonstrated that many of the landscapes which find favour in the eyes of Judges at our exhibitions owe their success to cloud effects, and, when the ordinary amateur notes this, he strives hard to go and do likewise. He has generally stored away landscape negatives without number which are terribly monotonous in their absence of clouds, and he looks forward to the time when he shall be able to wed them with suitable atmospheric effects and once more bring them to the light of day as new creations. But it must be confessed that Mr. Cadett's paper did not tend to help these owners of stored treasures, for he dealt exclusively with the possibility of securing clouds and landscape on one negative simultaneously.

It was somewhat unfortunate that Mr. Cadett had to commence his discourse with an apology, and, moreover, a double barrelled apology. In the first place, he spoke under the distressing grip of a bad cold, and, in the next, he had hoped to show a number of pictures taken in Switzerland, which pictures had failed to come out as he had intended. It is a comfort for insignificant workers to hear that an expert sometimes goes wrong (just as most persons are not grieved to hear of friends' misfortunes), and such workers, if any were present, must have chuckled when they heard the lecturer confess that he had failed to get his Swiss exposure meter adjusted for altitude, and had forgotten to back his plates. However, he was able to illustrate by means of other persons' pictures, the various points touched upon.

Some unkind critics had on a former occasion accused him of seeking, by means of a lecture, a gratuitous advertisement, and, as a manufacturer of dry plates, he was, of course, open to such remarks; but he would ask his hearers how he could, occupying the position which he did, avoid talking shop? He felt quite sure that at the Camera Club at least he would not be misunderstood.

Although generally he associated himself with the scientific side of photography, he was now more particularly to speak of it in its pictorial aspect. On many occasions he had seen very beautiful lantern slides exhibited on the screen before them, especially Swiss views, but he could not help noticing that, in some of the finest, the deep shadows were far too deep, while at the same time the high lights were burnt out. He thought that he would be able to show how such faults might be obviated.

In the first place, let them consider the range of the photographic plate, i.e., the range of correct gradation. This word "gradation" was not well understood, as we all found last week when, in the course of discussion upon Captain Abney's paper, he (the lecturer) had a little passage of arms with regard to it. Captain Abney maintained that a quick plate had a better range than a slow one, a statement with which he could not agree. But it was more than possible that they did not both define the word "gradation" in the same way, and were consequently speaking at cross purposes.

If densities or opacities on a plate are proportional to the light which produced them, they must be correct. A slow plate has a very extended range, and, although you hear people complaining of such plates giving hard negatives, it must be remembered that, by proper control in development, a slow plate can be made to give a picture as soft as may be desired. It was not to his interest as a manufacturer to cry up the

virtues of slow plates, for any one can make them, but he is bound to say of a slow plate that it will give a far greater range than a quick one. He would pass round two negatives, with positive prints, one of which was exposed for five seconds and the other for fifty seconds. The negatives were developed together for precisely the same time, and yet the two prints are absolutely identical. With a rapid plate it would be quite impossible to show such a result.

Now with regard to clouds. With an ordinary plate and screen, if we fully expose for the landscape, the clouds not only are over-exposed, but they become reversed. If, also, the cloud happens to reflect as much white light as the blue on which it is placed, the cloud disappears on the plate. If, therefore, we want to represent clouds, we must, by means of a proper screen, cut down the blue. Any screen which will do this is better than none, but, of course, it is best to have a screen which will do the work well, while at the same time it assists the other colours in the picture.

He would now show, by means of the lantern, three landscape slides taken by means of Mr. Sanger Shepherd's screens, one under blue, another under green, and the third under red, and it would be seen that there was very little difference between the green and the red. To compare with these, he would show some pictures taken with the spectrum plate through a mixed screen. The improvement was at once evident, but the increase of exposure was about forty times. It may be taken as a certainty that most photographs showing the presence of fine clouds have been due to the use of well-corrected screens and colour-sensitive plates.

The lecturer concluded his remarks by some observations upon the important subject of backing plates, and detailed some experiments which proved the great advantage of backing in obviating halation, and other markings due to internal reflection between the surfaces of a glass plate.

The Chairman (Professor Armstrong) described the paper as being both valuable to photographers as well as highly interesting, and he invited a discussion, which should be a full one, considering the number of experts who were present.

Mr. Bothamley alluded to the extraordinary latitude of many plates in the market, and to the possibility of obtaining the same printing results, provided that time were given to the experiments, from negatives of various exposures. He had often shown that very much improved results could be obtained with an orthochromatic plate and a simple yellow screen, and he might say that, as far as pure landscape went, such a screen met all his requirements. The yellow screen had the advantage also of not increasing the exposure over-much. Where clouds came in, the mixed screen would do better work, and they were indebted to Mr. Cadett for expending so much time and skill in perfecting it.

Mr. Sanger Shepherd said that fully one half of the beauty of a landscape resides in the clouds which hang above it, and, wherever there are clouds, especially white ones, the photographer who wishes to represent them accurately must use a screen corrected for all colours, for such a screen must naturally include white; but, where very little red comes into a composition, a yellow screen will do good work. A screen correcting blue and green only would be valuable for snap-shot work, and such a screen, if placed on the market, should have a wide future before it. But a screen for general work should be carefully adjusted for the plate employed, and not used for any other make of plate. You might as well put a sewing needle into a planing machine, in that you would be using a tool for a machine quite foreign to it.

Mr. Horsley Hinton could not agree with the remark of a former speaker as to the virtues of a yellow screen. He had tried every screen in turn, and none came up so nearly to his ideal as that produced by Mr. Cadett. It was difficult to secure clouds and landscape on the same plate, especially when cumulus clouds were presented on a blue sky, and he had found the Cadett screen to make the work easier than any other. He did not think that backing was an unmixed benefit to a plate. In some pictures he had taken the outline was so hard that he afterwards much regretted that the plates had been backed.

Colonel Gale remarked that he used ordinary plates for his landscape work, and printed in his clouds from separate negatives.

After a few remarks from Mr. George Davison and others, the Chairman said that the discussion showed that we were advancing to a marked extent. It was true that the use of orthochromatic plates and screens was not new, but there was a decided novelty in the employment of screens accurately adjusted to plates. He thought that we must all congratulate ourselves that we had among us a plate-manufacturer who was content and able to approach such an important matter from a scientific standpoint. Mr. Cadett has acted in the prosecution of these researches as a German manufacturer would have done—he could not pay him a much higher compliment.

Mr. Cadett having replied to the questions which the discussion of his interesting paper raised, the meeting came to a close with the usual vote of thanks.

#### AN AMERICAN EDITOR IN LONDON.

MR. F. DUNDAS TODD, Editor of the *Photo-Beacon*, publishes in his journal for October some photographic impressions obtained in London during his recent visit. It will be observed that Mr. Todd was not very favourably impressed with the things he saw—except what was of American origin.

"I rather reluctantly interrupted my usual programme and started for London in order to make a tour of those interested in photography and see whatever they had that was new. For five days I wandered round the big metropolis, and during that time saw only two things that I considered of sufficient importance to mention to my readers, and even one of these I am afraid will not be put on the American market. It is a new variation of colour photography on the plan of the Ives Kromskop, but is only possible with plates that are on the English market.

"The other should, I fancy, some day be introduced to the photographers of the United States, as it consists of a new film to be used either in roll or out-size form. A company is being floated to manufacture it in Britain, and those who are pushing it are very sanguine of its success. They show some excellent prints made from negatives made with the film, so that it has every appearance of being practicable. It has been dignified with the title of 'Secoco' film.

"I had the pleasure of seeing through the rooms of the Royal Photographic Society, but they are only in the transformation stage, so that they were not specially interesting. Very different was the Camera Club, which is housed in a very commodious building, comfortably furnished, where a man could spend many pleasant hours each day. I also visited one of the meetings of the Photographic Club, but, as it was the 'off' season, only five members were present, so that the meeting was very uninteresting.

"I was very much impressed with the difficulty of reaching the average business man in London. On entering the office a boy of about fourteen waits on you. He wants your name and address, full particulars of your business and intentions, and you wonder why he does not ask you to produce a certificate of good character signed by a clergyman and head of police. All these he dutifully lays before a youth a few years older than himself. He in turn puts you through a severe examination, and apparently notes the character of your pockets to see if you have anything in the nature of concealed weapons about you. He in turn reports to a higher authority, who leisurely surveys you from a distance so as to make sure of your respectability, then proceeds to put you through a regular cross-examination. Fully satisfied, he informs you that he will see if Mr. Blank is in. All this takes about ten minutes. At last you are asked to 'step this way,' and are shown to a room that is reached by a regular labyrinth. Here you rest for about five minutes, as Mr. Blank is busy just at present. At last he appears, looking most solemn and serious, for however much he may be full of fun outside the walls, an English business man must never smile between the hours of 9 a.m. and 6 p.m. Truly, if an Englishman's house is his castle, his office is the citadel. It seems to me that it would not do him any hurt if he met Tom, Dick, and Harry a good deal oftener, and learned what the public wanted instead of trying to sell them what he thinks it should have.

"I was much impressed with the average air of untidiness and neglect, not to speak of the antiquated fittings of the average London business man's office. His accommodation would simply be unlettable in Chicago, excepting to a poor class of tenants. I think I came across elevators only twice, and these were small, poky things, travelling at the rate of a mile in a thousand years. By the way, they are called 'lifts' in this part of the world, and this is claimed to be correct as you can lift a person either up or down, but you can elevate in only one direction.

"While doing a growl about offices, I may say I found one run on the American plan but it was an American company who owned it, the Vive Camera Company, and it was run by an American, Mr. Shedd. His door stands with the latch-string out, and there is a clear road from the door to his desk. The latter, by the way, was the only decent desk I saw in all my travels, in fact it was a beauty and was made in Chicago.

"And right here I may as well make a confession. In starting from Chicago my better half and I had a conversation during which we discussed the differences between what we were leaving and what we were about to see. At length we agreed that the Americans were the more practical people, but the old-country people could beat them in style. We take it all back, and humbly acknowledge that, whether it is household fittings, office arrangements, dress, or tools, the Britisher has much to learn."

#### PRECIPITATION OF GOLD FROM CHLORIDE OR BROMIDE SOLUTIONS CONTAINING IT.

MESSRS. FREDERICK WILLIAM MARTINO and FREDERIC STUBBS' invention relates to improvements in the precipitation of gold from chloride or bromide solutions containing it, the solutions referred to being such as are produced in the well-known "chlorination" process and the less-known "permanganate" and "bromide" processes.

The essential feature of the invention is the employment, for precipitating gold from the above-mentioned solutions, of metallic carbides, which, when brought into contact with water, produce a hydrocarbon gas, or the employment of such hydrocarbon gases, however they may be manufactured.

Carbides of the metals of the alkaline earths, calcium and barium carbides, for instance, produce acetylene when treated with water, and methane is produced in a similar manner from aluminium carbide.

In the following specification the terms "metallic carbide" and "hydrocarbon gas" are to be understood as referring respectively to the carbides and gases above mentioned.

In carrying out this invention, a hydrocarbon gas is passed through a chloride or bromide solution containing gold, or a metallic carbide is added to the liquid, thus producing a nascent hydrocarbon gas; in either case the chloride or bromide of gold is decomposed and the metal precipitated.

If the chloride or bromide solution contains free chlorine or free bromine, it may be found advisable, before treating the solution by the method herein described, to remove the excess of chlorine or bromine by any convenient process, preferably by passing a current of air through the solution, in order to avoid the waste of metallic carbide or hydrocarbon gas which is necessary to neutralise these elements before precipitation commences.

In the permanganate process the small quantity of permanganate present in the solution of auric chloride is immediately decomposed by the metallic carbide or hydrocarbon gas, and precipitation of gold then proceeds rapidly.

Heat from any outside source may, if desired, be applied during any of the stages constituting this improved process; for instance, the chloride or bromide solution may be heated before or during treatment by passing steam through pipes immersed in it, or the vessels containing the solution may be steam-jacketed.

### "LE SALON DES FUMEURS."

BY AN OUTSIDER.

THIS is not a public-house sign, it is not a secret password of the Boers nor is it an expression to indicate that the writer is sitting in the smoking saloon on board a French steamboat—nothing so vulgar as all these things, but something infinitely higher, nobler, and more artistic. It is a description, culled from my old French friend on the mantelpiece, to express (like the polished parlance of the invitation card) its English equivalent (?), viz., the "At Home" of the Photographic Salon, given at the Dudley Gallery, on Tuesday evening, the 17th instant, of blessed memory.

Now, though this was called an "At Home" it wasn't really an "At Home," although everybody thought it was an "At Home," but, then, everybody was wrong, not really wrong, you know, but not quite right, for the grey slip called it a "Smoking Conversation," and surely this must have been correct, as the grey one also announced, in very small letters, as if ashamed of the fact, that "sherry" and "Scotch whisky" were to be had, and also "sandwiches of ham," "pâté de foie gras" (with all the accents carefully placed) "anchovy," "sardine," "caviare," "and shrimp." Truly a feast for the never-hungry gods. I don't know whether there was a supply of the delectable fluid made from a certain celebrated brand supplied gratis by the Mazawattee Company, but I do know that that night I dreamt that there was a great tea sale at the Egyptian Hall, and that every purchaser of one packet of this marvellous compound would be presented with a Salon picture. There was a run on the tea, but nobody would take the pictures. Of course, this was only a dream, and I have a shrewd idea how it was I came to dream that dream. It was the fault of the waitresses. I said waitresses, not that they were really waitresses, but everybody thought they were, and so did I till I had partaken of two sherries and sodas, given in mistake for whisky, of course. Still that accounts for the dream—and "other things."

Many and distinguished were the guests, and I was glad that I had been able to borrow my old dress suit from my uncle's for the auspicious occasion so that I might meet some of the Royal Buckhounds and hear the bleatings of the "Linked Lambs" at one and the same moment. It was, indeed, a sight worthy to be photographed, and it was done. That photograph will contain a collection of faces and forms associated in the eyes of the world with Literature, Science, Music, Painting, and, let us hope, Pictorial Photography, as well as of men connected with the more vulgar forms of earning a livelihood.

Linked rings became the order of the night—small tables with gradually enlarging circles were seen all around the room. Conversation became more lively as the potent fluid circulated and the smoke got thicker. The portraits on the walls seemed to unbend and smile more sweetly than one would have thought possible in visages so stern, the eyes would appear to twinkle through the smoke and we all felt comfortable. Our senses were lulled by dulcet sounds the like of which one would never have suspected to emanate from the throats of savages. Yet the savages with one exception provided the amusement of the evening.

Speaking of photographs on the walls recalls a little incident which took place early in the evening. It was something like this:—

First Spectator (A): I say, Bill, look here, what's this (looking at No. 1004, vide catalogue)?

Second Spectator (B): Don't know—think they've hung it wrong side up, but it's a landscape any how.

(A): Not it; those black things are not trees, they are figures. It's a funeral procession—but here's Charlie, let's ask him.

(Charlie approaches.)

(B) to (C): I say, Charlie, come and tell us if this isn't a landscape.

(A pause of fifteen minutes during which Charlie has been scrutinising the print.)

(C) (sighing): Give it up old chap, can't make head or tail of it (passes on).

I sighed too when I heard this, and thought what heathens there are in the world, to be sure! Just think of it—not to be able to appreciate the beautiful pictorial creations of the *élite* of the photographic Salonians! sentiment is non-existent in the breast of the casual observer, and his powers of artistic appreciation are a minus quality!

But, in spite of the foregoing incident, I managed to get a back seat—a camera obscura kind of seat where I could survey the kaleidoscopic mass of humanity around, and for even an every-day observer of faces and amateur character student there was plenty to see and study at the Dudley Gallery. Some day the world will be startled by the publication of "Moustache and Whisker Studies" but it wants the pen of a Dickens to do it. What food for his pen he would have found at the Salon Smoker!

There was the man "whose moustache went up under his nose, and whose nose came down over his moustache," when he smiled. "The Dundreary," the "Zola," the curly American combine, the fierce military, the "Kaiser," the "Sims Reeves" (with hair to match), the "Whisp," and the "Whacker." All these, and many more, in combination with bald pates, coal blacks, greys, browns, shorts and longs, curls and straightens—in fact, heads of the thoroughly representative cosmopolitan kind; but the curious part about it to me was that not one of the persons present looked as if he ever soiled his hands with pyro stains. I should have taken the company for anything but photographers, but this is, no doubt, owing to my ignorance of the "genus photographic." Yet stay, there was a gentleman with a velvet coat and enormous pipe who did look like a photographer, but I was told he wasn't one.

The warlike spirit was absent from this gathering; the feeling of amity was such that even the suggestion of a popular patriotic song, such as "Soldiers of the Queen," was tabooed, and "The Old Rogeroo" was left at home (perhaps for fear of wounding the delicate artistic sensibilities of the Salonians), though the Savages, no doubt, would vastly have enjoyed the same, together with the chorus thereof.

Foremost amongst the performers was Mr. William Nichol, whose mellifluous notes stole sweetly o'er the photographic soul, filling it with peaceful balm (not German yeast). Mr. Reginald Groom enunciated sweet sounds, in spite of the nicotineous atmosphere, and Mr. Odell was funny. Mr. John Edwards was imitatively Irish in his humour, and Mr. H. Severn told a sensational story—not really a sensational story, but everybody thought it was a sensational story until they heard it, and found they had been "had" by the reciter's comicalities, which were productive of much laughter. Mr. David Devant took us into the land of shadography (without the w), and called forth frequent applause from the clever "handling" of his subject. When the sandwiches were all devoured, the whisky and sherry all gone, our own and everybody else's tobacco at the lowest ebb, the Lion and the Lamb did a mutual growl, agreed to differ amicably, and went to their respective lairs.

### CROYDON CAMERA CLUB EXHIBITION.

AFTER an interval of some years the Croydon Camera Club has held its third Exhibition of photographs. The Exhibition, which was open from the 18th to the 24th inst. at the Art Gallery, Park-lane, Croydon, reflected great credit upon those who organized and carried it out. The Gallery was admirably adapted for the purpose, the pictures well arranged, and the average quality of the work very fair.

The Judges were Mr. A. Horsley Hinton, Rev. F. C. Lambert, and Mr. Percy S. Lankester. That they considered twelve of the 137 entries in the Members' Classes worthy of being medalled might be taken to indicate that there was an extraordinarily large proportion of meritorious work. The explanation is, however, that there were six classes, and, while we are bound to say that the members' work was, as a whole, distinctly creditable, we must once more make a strong protest against the system of unnecessarily multiplying classes, the result of the system being that photographs which would be hopelessly out of competition if entered in the subject classes to which they belong receive medals, because the negatives were taken under some particular circumstances.

As one would expect in the Exhibition of a society in which Mr. Jas. Packham takes a leading part the gum-bichromate process was well represented, in fact, nearly one-fifth of the pictures were printed by that method; but we left the Exhibition still unconvinced that the process, as a photographic process, supports the extravagant claims that have been made for it. That, with its assistance, it is possible to make a photograph unlike a photograph, and, perhaps, indeed, to avoid the bad qualities of some photographs, there was evidence to show; but there was an equal amount of evidence to show that the remedy is generally worse than the disease. Still, we must admit that there were a few examples beyond reproach in any respect.

In the open classes, the Champion Class was, as usual, a weak one, and, in itself, an object-lesson in the absurdity of indiscriminate medal-giving. Still, there was some good and representative work, Fred Marsh's well-known pictures of *Gasworks* taking the gold medal. The

general class contained a very fair proportion of interesting pictures. Among the well-known names we noticed were H. K. Foster, W. Illingworth, E. Marriage (silver medal), J. I. French, J. Leslie T. Shawcross (bronze medal), J. H. Avery, Mrs. Welford, Messrs. Byrne & Co., C. Speight, W. Howell, and W. H. Mayna. A class open to all amateurs residing in Croydon attracted quite a large entry, several of the competitors being ladies, and one of them, Miss May Donaldson, was fortunate enough to secure two of three awards.

The Lantern Slides Classes were unusually large, twenty-two sets being entered by members, and sixteen in the open classes, and the average quality was good. We were glad to find a class for stereoscopic transparencies and prints, but to notice that, although it was an open class, the five sets were all sent by members.

The competitive classes were supplemented by a loan collection. The five series of window transparencies of large size by Mr. Henry Stevens afforded the visitors an opportunity of seeing examples of the very highest class of technical photography. No less interesting and instructive was the collection of Alpine and snow scenes by Mrs. E. Main; Messrs. Percy Lankester, Lyddell Sawyer, and W. D. Welford also contributed, and the Platinotype Company had a collection of platinotype prints, mostly copies of paintings.

Lantern shows were given each evening and X-ray demonstrations. On the tables, colour photography was represented by Ives's Kromskop.

The following is the list of awards:—

#### MEMBERS' CLASSES.

Class A (Landscape, Seascape, and River Scenery).—Silver medal, Jas. Packham; bronze medal, L. Kough.

Class B (Portraiture, Figure Studies, Animals, and Flowers).—Silver medal, E. A. Salt; bronze medal, T. H. Towley.

Class C (Architecture).—First award, Hector Maclean (medal declined).—Silver medal, W. H. Rogers; bronze medal, G. W. Jenkins.

Class D (Enlargements).—Silver medal, A. E. Isaac; bronze medal, L. Kough.

Class E (Pictures taken at Club Excursion).—Silver medal, G. W. Jenkins; bronze medal, no award.

Class F (Hand-camera Work).—Silver medal, F. W. Hicks; bronze medal, H. Moore.

Class G (Lantern Slides).—Silver medal, G. W. Watson; bronze medal, H. E. Holland.

#### OPEN CLASSES.

Class H (Champion).—Gold medal, Fred Marsh.

Class I (Picture not previously medalled—any subject).—Silver medal, E. Marriage; Bronze medal, J. Leslie T. Shawcross.

Class J (Open to amateurs residing in Croydon).—Gold medal (withheld); silver medal, Miss May Donaldson; bronze medal, W. H. Roger; Bronze medal awarded to Miss May Donaldson, but withheld.

Class K (Lantern Slides).—Silver medal, A. E. Smith; bronze medal, Edgar Bull.

Class L (Stereoscopic Transparencies and Prints).—Silver medal, G. W. Watson.

## Our Editorial Table.

MERRETT'S TRIMMING DESK.

Marion & Co., Soho-square.

It is claimed for this form of photographic print-trimmer that it possesses simplicity of action, with the minimum of labour and greatest speed, and gives perfect results; and that it will trim either paper or cardboard, divide negative films, midjet prints, &c., with great rapidity. The

instructions for use are: Place the print on the desk, allowing the part to be trimmed off to pass under and beyond the steel band at the top, then, while holding the print in position, press the desk down as far as it will go. The cut is thereby made, and, upon releasing the pressure, the desk rises automatically, ready for the next cut. A rule gauge fitted to each desk ensures accuracy in cutting.

#### THE ILFORD MANUAL OF PHOTOGRAPHY.

By C. H. BOTHAMLEY, F.I.C., F.C.S. Price 1s. Ilford: The Britannia Works Company, Limited.

Of the many books that have been compiled for the instruction of those taking up the practice of dry-plate photography, this is one of the few

that could least be spared. It is late in the day to single out for praise a manual which has reached its hundredth-thousand copy, but we are bound to say that, in again making the acquaintance of Mr. Bothamley's book, we are struck as forcibly as ever with the wide and intimate knowledge of theory and practice which he brings to his task, and with the soundness and clearness of his teachings on the optics, chemistry, practice, and other phases of his subject. We can conscientiously give the *Ilford Manual* the heartiest recommendations. The book has been brought up to date throughout, reset with new type, a chapter added on "Platona," and also an appendix treating on "Photographic Chemicals, How to Keep and Use Them." These additions and improvements constitute the book as complete as it is useful.

The Company kindly furnish us with the following interesting data on the subject: "The whole of the hundred thousand have now been sold, and we have just received 5000 more copies from the printers, more than half of which are disposed of. It is unnecessary for us to point out that it is only the few publications which reach such figures as these, even in general literature, whilst in a photographic book such figures are never reached. The success of the *Ilford Manual* is therefore the more gratifying to us, and reflects great credit on the author. From a business point of view we are proud to feel that we have been, more or less, the means of adding a hundred thousand workers with 'Ilford' goods to the already long roll of our supporters. What this means in sales will be appreciated even by those who have no knowledge of the subject."

Both the publishers and the author may be congratulated on the continued success of the *Ilford Manual*, which is a handsome book, and thus, in addition to its practical value, makes a worthy addition to the photographer's library.

#### PHOTOGRAMS OF 1899.

Compiled by the Editor and Staff of the *Photogram*, assisted by Mr. A. R. C. CARTER. 192 pp. Price 3s. London: Dawbarn & Ward, Farringdon-Avenue, E.C.

We have no doubt that amongst the many photographers who annually add *Photograms of the Year* to their library, some curiosity will be aroused as to the manner in which Mr. A. R. C. Carter has acquitted himself in the position of successor to the late Gleeson White as critic in chief of the two "great" Exhibitions. Mr. Carter, in our opinion, easily justifies his choice, for he writes clearly and instructively of the photographs, and with an absence of that high falutin and meaningless jargon which is only too frequently the sole stock in trade of the art critic who condescends to criticise photographs. Mr. Carter is in close touch with his public, and we are convinced that the producers of the photographs he criticises can profit by what he has to say of them. For the rest, *Photograms of the Year* 1899 preserves the main features of its predecessors. The principal R.P.S. and Salon photographs are reproduced; the Continent, the United States, and the Antipodes have been laid under contribution for representative work, and interspersed throughout the book are examples not hitherto publicly shown. All concerned in the production of the book have done their work extremely well. Our set of *Photograms of the Year* has an honoured place on our bookshelves, and we find it of constant and increasing value for study and reference. The latest addition to the series takes its assigned position as a matter of course, and we can give it no better welcome than the hope that it may be followed by innumerable successes just as great.

#### CATALOGUE RECEIVED.

Walker & Co., 19, Bridge-street, Aberdeen.

HER MAJESTY the Queen has several times honoured Messrs. Walker with a command to give cinematograph and optical lantern entertainments at Balmoral Castle. Their catalogue extends to over forty pages, and it appeals to those who wish to take advantage of the facilities which the optical lantern offers for winter-evening entertainments. We note the word "cinematograms" in Messrs. Walker's catalogue.

## News and Notes.

PHOTOGRAPHIC CLUB.—November 1, at eight o'clock. Annual General Meeting.

ROYAL PHOTOGRAPHIC SOCIETY.—Monday, October 30, "Surrey Commons, Ponds, and Rivers, &c.," by T. M. Brownrigg; Wednesday, November 1, "Animals studies," by Mr. Charles Reid; Saturday, November 4, "Belgium Revisited," by W. D. Welford.

MESSRS. FUEBST BROS., of 17, Philpot-lane, London, E.C., are issuing the following cinematographic pictures relating to the war:—1. Sir Redvers Buller's embarking on *Dunottar Castle* at Southampton, October 17, 1899; 2. (a) Sir Redvers inspecting the ship, (b) Sir Redvers bidding farewell from the bridge; 3. The ss. *Dunottar Castle* leaving the dock; 4. Coldstream Guards embarking on troopship *Gascon* (close view); 5. Coldstream Guards embarking, showing the Royal Engineers in the foreground; 6. Departure of troopship No. 4 (*Nubia*) with Scots Guards on board.

**THE Hon. Secretary of the Southsea Amateur Photographic Society.** 10, Ordnance-row, Portsea, writes: "I should feel particularly obliged if you could draw attention to the date of our Twelfth Exhibition, viz., January 29-31, 1900. It promises to be a big affair. There are five open classes, and one for beginners only. Prospectuses, &c., may be obtained from me on application."

**X RAYS AS A DEPILOYER.**—The following comparatively old story is still going the rounds: "People will do well to tight shy of the X rays as a depilatory. A lady was placed opposite a tube for twenty minutes, four days in succession, and she came to the conclusion that the result of the experiment was just nothing at all; but, after a week had elapsed, she found that the rays had removed not only the superfluous hair, of which she desired to be rid, but the skin also."

**THE Whitehaven Y. M. C. A. Camera Club's Exhibition of Photographic Work** will be held in the Assembly Rooms, at the Baths, Duke-street, Whitehaven, on Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday, December 4-9. Entry forms and all further information can be obtained from the Secretary, Mr. W. E. Mason, 67, Duke-street, Whitehaven. The following is the schedule of Classes:—Open to amateurs only, within the counties of Cumberland and Westmoreland: A, Landscape or seascape (any size); B, Enlargement (any subject), not less than four times enlarged; C, Lantern slides, set of four slides (any subject); D, Figure studies and portraiture. Open classes, for amateurs and professionals: E, Instantaneous work (hand or stand camera), subject to show evidence of motion; F, Landscape or seascape (any size); G, Enlargement (any subject); H, Figure studies and portraiture; I, Architecture. Open only to amateurs resident in Whitehaven or within a radius of two miles: K, Hand-camera work; L, Set of four prints.

**NEXT CENTURY'S ECLIPSES.**—As to eclipses in the coming century, says a contemporary, there will be about 380 of them, the number of solar being to the number of lunar in about the ratio of four to three. What is of very rare occurrence in a calendar year will happen in 1935, the first time since 1823, viz., seven eclipses, the largest number that can happen in a year. There are eight total solar eclipses predicted to occur visible in the United States, in 1918, 1923, 1925, 1945, 1954, 1979, 1984, 1994. There will also occur twelve transits of Mercury on the following dates: November 12, 1907; November 6, 1914; May 7, 1924; November 8, 1927; May 10, 1937; November 12, 1940; November 13, 1953; November 6, 1960; May 9, 1970; November 9, 1973; November 12, 1986; November 14, 1999. The first, second, ninth, and tenth will be wholly visible in the United States; the seventh and eighth only partially so. A transit of Venus, however, which is of much more consequence, will not occur within the next century. The earliest date predicted is June 8, 2004.

**THE Judges for the Borough Polytechnic Society's Annual Exhibition, to be held on December 27, 28, 29, and 30, are the Rev. F. C. Lambert and Messrs. John A. Hodges and E. J. Wall.** Gold and silver medals are offered in the open classes. Entry forms are now ready, and can be had of the Hon. Exhibition Secretary, Mr. E. J. Hoar, 59, Hillingdon-street, S.E. The monthly print competitions, in connexion with the Society's summer outings, have just been concluded, and Mr. E. W. Burch is hailed the winner of the greatest number of points, and therefore receives a silver medallion. The popularity and success of these competitions have prompted the executive to institute a series of lantern-slide competitions throughout the ensuing winter. Points will be awarded for each slide by two qualified Judges selected from the members, who will criticise all slides and advise as to the best means of improving them. The winning slides and any the Judges may select will go to form a collection, which may be borrowed by any member for a period not exceeding fourteen days. A silver medal, bronze medal, and certificate are offered.

**RE HENRY BARROW TREVETHICK, photographer, 1, Orchard-street, and 36, Fife-street, Sheffield.**—The first meeting of the creditors interested under this failure was held at the offices of the Official Receiver for the Sheffield district, on Thursday, under the presidency of the Official Receiver (Mr. J. C. Clegg). The Official Receiver, in his report, stated that debtor owed 292. 11s. 6d. to unsecured creditors, and had a deficiency of 255l. 15s. 11d. Prior to 1897 he was in partnership. That partnership was dissolved, and he had carried on business since on his own account. He had been insolvent for a considerable time. According to his own account, he owed 100% more than he was able to pay twelve months ago. Since that time he had incurred other liabilities, and had increased his loss by nearly 100% by attending balls, exhibitions, and the like. He supposed, like other debtors, he had hoped to pull round, but, instead of doing that, he had gradually got worse. Debtor said his bankruptcy was due to bad trade and want of capital. No resolutions were passed, and the estate will therefore be wound up by the Official Receiver in the usual manner.

**ELECTRICITY AS A LIGHTHOUSE ILLUMINANT.**—The correspondent of a contemporary claims that extended scientific examination of the matter, based upon the best opportunities of judgment, have more and more led to conclusions unfavourable to the employment of the electric arc for lighthouse purposes—that, in clear weather, other lighthouse illuminants are amply sufficient in power, and the electric light is very apt to mislead the navigator as to his distance from the light, while, in hazy or foggy weather, repeated observations, alike by mariners and scientific men, have shown the inefficacy of the new light, even of the most powerful description and in a lighthouse of the first order, though this, it is admitted, may be due in part to the fact that rays of high refrangibility, such as are emitted by the light in question, are more largely absorbed by a fog than rays of lower refrangibility that are emitted by oil or gas. Another more potent cause, in the estimation of this writer, lies in the very condition which gives the arc light its great value for optical uses, namely, its concentration in a minute area compared with oil or gas, but regarded as a positive disadvantage for a lighthouse illuminant in foggy weather.

**SANDELL "PERFECT" COMPETITIONS.**—The following are the results of the September competition:—10l. prize, three snap-shots—*A Torn Sail, Sunset, and Storm Clouds*, Mr. T. E. Corney Wilson, Liverpool; 5l. prize, *A Sail-maker's Loft in Old Portsmouth, West Porch, Canterbury Cathedral, St. Gabriel's Crypt*, Mr. F. J. Mortimer, Portsmouth; 1l. prize, two studies—*Now I'm Granny, and Inattentive Scholars*, Mr. A. Durn, Wotton-under-Edge; *Three Architectural Studies*, Mr. E. A. Spivey; two studies—*At the Smithy Door, and In Eads Colne Church*, Mr. C. S. Tyler, Earls Colne; three snap-shots—*Fast Falls the Even-tide, The Sun is Sinking Fast, and The Darkness Deepens*, Mr. T. R. Beaufort, Westminster; *Interior, St. Peter's Church, Drogheda*, Mr. Alex. B. Hogg, Belfast; *Christ Church, Bristol*, Mr. Harold E. Brightman, Bristol; *Ornamental Food-house*, Mr. William Robinson, Clapham Junction; three studies—*Interior of Morning Room, The Harvest Field, and Drilling*, Mr. J. T. Newman, Berkhamstead; three studies, *One Cloudy Summer's Evening, Bathing, and Lilium Auratum*, Mr. Percy F. Coggin, Chelsea; *The Solent, from Cowes Parade*, Mr. W. C. Hope, Cowes.

**MESSRS. NEWTON & Co., of 3, Fleet-street, E.C., are issuing the following slides, which are of great interest at the present time:—The Transvaal: Map of South Africa; Bloemfontein—General View, English View, Market Square; Group of Kaffirs and Hut; Crossing a Drift in Ox-wagon; Van Staaden's Pass, Starting from Camp; Durban—Town Hall, West Street; Johannesburg—The Reef, The main Reef, The first House built, the Market-place; Kimberley—View of the Railway, Market Square, Diamond Mine, De Beer Mine, Compound of De Beer Mine, Searching Nigger for Diamonds; Natal—Karoo Kloof Falls, Harbour, Pinetown Kaffirs at Pool; Port Elizabeth main Street; Pretoria—Government Buildings (Road Saal), Camping out of the Dutch before the Nachmaal; Transvaal—Stage Coach, Gold Diggings; Major Wilson's Last Stand; Floreat Etona at Laing's Nek; Burial-ground at Laing's Nek; Jameson's Raid—The last Stand; Sir George White, V.C., on Horseback; Sir Revers Buller; President Kruger at home; Boers returning from Market outspan on the Trek, examining the new Rifles; Boers' Commando leaving for the Front; Field Cornet delivering Orders at a House. Wireless Telegraphy: 1. Portrait of Professor Hertz, with autograph; 2. Standard Hertz resonator; 3. Professor Oliver T. Lodge's portrait; 4. Syntonic Leyden jar experiment; 5. Spiral-wire coherer; 6. Diagram of Lodge's experiments with receiver enclosed in metal; 7. Lodge's alternative arrangements of insulated capacity areas for long-distance signalling; 8. Lodge's coherer and diagrams of complete coherer circuits; 9. Lodge's and Muirhead's improvements in syntonic telegraphy, showing all connexions for a complete station; 10. Portrait of Sir W. H. Preece; 11. Diagram of apparatus for magnetic induction, showing principle of Preece's system as adopted by the Post Office; 12. Preece and Lodge's recent improvements in magnetic space telegraphy; 13. Complete arrangement showing connexions, &c.; 14. Signor Marconi's portrait; 15. Marconi's short-distance apparatus; 16. Marconi's receiver and transmitter; 17. Receiving apparatus with cover removed; 18. Wireless telegraph station at the South Foreland Lighthouse; 19. The Marconi transmitter in the lighthouse, connected for telegraphing to Wimereux; 20. The receiving apparatus at the lighthouse connected up; 21. The mast carrying the vertical wire at the South Foreland Lighthouse; 22. Receiving a message at the South Foreland Station; 23. The mast at the Wimereux Station; 24. Receiving a message from Dover at Wimereux; 25. Facsimile and transcription of dot-and-book message sent by the Queen from Dover to Wimereux to the Mayor of Boulogne.**

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
30.....	Bradford Photo. Society .....	{ Instantaneous Photography. Harry B. Buckley.
30.....	Camera Club.....	{ Some Principles of Development. Alfred Watkins.
30.....	Kingston-on-Thames .....	{ India and Ceylon. J. D. Gibson.
31.....	Birmingham Photo. Society ..	{ Extraordinary General Meeting.
31.....	Hackney .....	{ New York and Washington. W. A. Ellington.
November.		
1.....	Photographic Club .....	{ Annual General Meeting.
1.....	Southsea .....	{ Demonstration: Multiple-coated Plates and Films. J. T. Sandell.
1.....	West Surrey .....	{ Scenes in the Isle of Man. W. G. Rowse.
2.....	Camera Club .....	{ Scenery in the Canary Islands. T. O. Porter.
2.....	Liverpool Amateur.....	{ Lantern in Use.
2.....	London and Provincial .....	{ Demonstration: The Biokam. The Warwick Trading Company.
3.....	Ashton-under-Lyne.....	{ Elementary Photography Class.

### ROYAL PHOTOGRAPHIC SOCIETY.

OCTOBER 24,—Technical Meeting,—Mr. G. Scamell (Hon. Treasurer) in the chair.

#### LIGHTNING AND ELECTRIC LAMPS.

The Hon. Secretary showed a frame of prints, sent by Mr. Sidney Webb, of Dover, through Sir H. T. Wood, exhibiting some curious phenomena which occurred during thunderstorms, the lightning playing in a very singular manner among the electric arc and glow lamps on Dover Pier.

#### THE WELLINGTON FILM.

Mr. H. WADDE read a paper upon the subject of the new Wellington film, a transparent negative film supported during exposure upon a paper backing. It may be exposed either in rolls or cut sheets, or in the form of "daylight."

cartridges." After exposure it is developed by any of the customary developing solutions, preferably pyro ammonia, and after immersion for a quarter of an hour in an alum bath it is fixed and washed, and then squeegeed down to dry upon a thoroughly clean sheet of glass or ferrotype. When dry, the film may be separated from the paper support, but the latter is very translucent and free from grain, and printing can be carried on without stripping if desired. The stripped film is flexible, possesses a fine matt surface, which much facilitates retouching, and may be varnished by being dipped in a varnish requiring no heat. It is made from the purest photographic gelatine, and, as the entire support is chemically inert, the keeping qualities of the film are equal to those of a glass plate. The speed numbers are 80 H. & D., and 56 by Wynne's exposure meter, but it is claimed that the backing of white paper acts in such a manner as to give an increase of the actual exposure, and that the films are therefore sufficiently rapid for hand-camera work. The negatives possess great delicacy of gradation and fineness of grain, and are entirely free from halation, and may be printed from the reverse side without loss of definition, a very convenient feature for carbon and colotype work. The process of stripping was demonstrated by Mr. Wade, and is exceedingly simple and certain, it being only necessary to cut through the gelatine film, insert the point of the knife between the latter and its support, and then pull them gently apart. A number of negatives on roll, cut, and daylight films were shown, together with prints from front and back, and some enlargements; and they certainly justified all that had been said on their behalf.

Mr. T. BOLAS said that for a good many years he had considered himself the originator of the "daylight cartridge" system, which he described at a meeting of the South London Photographic Society in, he thought, the year 1885; he had, however, quite recently discovered that his idea had been "stolen by the ancients," for in 1855 it was fully detailed by an Indian officer, Captain Barr, in *Notes and Queries*.

Mr. J. B. B. WELLINGTON, in reply to some questions as to the manipulation of the film, said the pyro-ammonia developer was recommended because it had no deleterious effect upon the paper support. Pyro soda answered very well if development was not continued for more than fifteen minutes, but, if that time was exceeded, there might be a difficulty in stripping. It was very important that the negatives should be kept in motion whilst in the various solutions, and particularly when in the fixing bath. The use of the alum bath was essential in order to keep the films flat during subsequent operations, and formalin could not be employed as a substitute.

Mr. F. W. JACKSON said that Captain Gladstone had used films in a 12x10 hand camera, keeping them flat by pressing them upon a carrier tablet coated with a tacky substance, and he suggested that a similar plan might be adopted when using the Wellington films.

Mr. WELLINGTON, however, said the plan would not answer in this case, as the paper support would absorb the moisture in the tacky substance, which would consequently require frequent renewal.

Mr. BOLAS thought the difficulty would be overcome by coating the carrier with lead plaster, which would retain its tackiness for any length of time.

The CHAIRMAN had used the films with much success, developing with metal soda; he had put a number of negatives together into the hypo bath and allowed them to remain without moving until fixation was complete, and, when washed and dried, they stripped as readily as others which had been carefully kept in motion.

#### THE PRESIDENT.

The Earl of Crawford was present at the meeting, and was heartily congratulated upon his restoration to health.

#### COMING EVENTS.

November 7, lantern lecture at 5a, Pall Mall East, "Some Mediaeval Towns of Germany," by Mr. J. J. Vezey, with lantern slides from negatives by Commander C. E. Gladstone, R.N. November 14, Ordinary Meeting at 66, Russell-square, when the general business will be followed by the second Traill Taylor Memorial Lecture, on "The Teachings of the Daguerreotype," by Major-General J. Waterhouse, I.S.C.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 19.—Mr. A. Mackie in the chair.

Mr. R. P. DRAGE expressed surprise that photographic chemists had done so little to place methods of combined toning and fixing upon a scientific and definite basis. A perfect understanding of these methods was a thing to which he looked forward with a keen interest, and he hoped that some steps would soon be taken to compass the end he had in view. In the making of prints by the combined method, they were told that no preliminary washing was required, but that the prints ought to be immersed in a dry state, with all the free silver they contained. In the case of separate toning and fixing, a certain period of washing was, however, obligatory, and he was very anxious to do away with this, and to simplify the whole matter as far as might be consistent with permanence.

Mr. S. HERBERT FRAY, although neither an advocate of the combined or the separate method, believed that the keynote to success with the former was to allow definite quantities of gold to each sheet of paper to be toned, and to use the bath once, and once only.

The CHAIRMAN did not know that it was necessary to wash P.O.P. prints in water prior to toning by the separate method, as intimated by the member who introduced the subject. He never did it himself. He usually put salt in the sulphocyanide bath, and found with this that the prints could be put in dry. The immersion of the prints in a dry state was not convenient if many prints had to be treated, however, on account of sticking together, and in such cases he would put them first in salt and water. He also put salt in the toning bath, and found no necessity to rinse the prints between their emergence from the salt bath and entry into the toning bath. He rather thought that the maker's formulae were often too implicitly followed. He suggested that Mr. Drage should conduct some experiments on the lines indicated.

Mr. PHILIP EVERITT asked for a formula for the platinum toning of matt P.O.P. for sepia tones.

Mr. WALTER D. WELFORD said that he had succeeded best with Marion's formula on Paget paper. The result was dependent entirely upon the paper used, tones varying with the many different makes.

Mr. EVERITT said that there were plenty of recipes for black tones, but not so for the sepia tones, which he wanted.

The CHAIRMAN added that many P.O.P. prints emerged rather badly from the plain platinum bath. The colours of these he had altered to his taste by fixing and washing and again toning in sulphocyanide and gold.

Mr. HARRY WADE read a paper upon

#### THE WELLINGTON FILM.

He assumed that he was addressing an audience of amateurs, for to them the film was likely to appeal more directly. Amateurs, as a rule, followed the pursuit of photography in order to afford themselves pleasure. They looked at photography as an agreeable hobby, and with this view in mind manufacturers of apparatus and materials were striving to make everything of the lightest construction consistent with strength. But of what use, he continued, was the light camera and tripod if heavy glass plates were obligatory? It was ourselves who were not consistent, consequently our sensitive medium must be of a similarly light nature. We have had celluloid films for some time; but so far, in competition with glass plates, they have been behind. There remained, then, still an opening for a reliable substitute for glass plates, at the same time of a reasonable price, although the latter consideration, to the man who wanted the best possible results, was only of secondary importance. He submitted that the Wellington film more nearly answered the ideal requirements of photographers than anything yet made from the point of view of lightness, facility of storage, and applicability to every circumstance. The film had all the advantages of celluloid without its disadvantages; it was as good as a glass plate as regards its evenness of coating and general freedom from defects, without its weight, and it could be used in sheaths, roll-holders for daylight changing, and in the ordinary dark slides. The construction of the film was described as a transparent sheet of the purest gelatine, supported upon a paper backing of a very grainless kind, the emulsion being coated upon the said gelatine surface. Double the keeping qualities of celluloid films was claimed for the new film, which was also equal in the same respect to glass plates. The film was not of that inflammable nature which marred the prospects of celluloid. The emulsion was perhaps not the most rapid, but it was very rich in silver, and the negatives would hold their own for delicacy, brilliancy, gradation and fineness of grain. A strong point in favour of the film was that it could be equally well printed from either side. For carbon printing, the colotype process, &c., it was thus of great value. Double transfers and reversals would be things of the past. Halation was unheard of with the film, and the messy backing operations were therefore unnecessary. Manipulations were the same as for plates. The speed of the emulsion was given as 80 H. & D., or 56 Wynne. But, whilst this is the speed of the emulsion, the speed of the film is much higher on account of the paper support, which appears to absorb the light or keep it in the film, thus giving an increase of exposure. The film is sufficiently rapid for hand-camera and instantaneous work. Any developer may be used, but pyro ammonia is specially recommended. Mr. Wade said, however that he had successfully used others, and showed results in support of this remark. After development the film is well washed, and immersed for ten or more minutes in

Common alum .....	2 ounces.
Water .....	40 "

It is again washed, fixed in an acid or ordinary hypo bath, and finally washed for an hour. The negative is then squeegeed to a ferrotype plate, and dried in a cool place. The negative will be found to detach itself when dry. It is quite possible for the negative to be used for printing on its paper support if so desired; but, if a transparent negative is required, the film must be stripped from the paper. Before this can be done, the whole thing must be quite dry. A cut is made through the gelatine at one edge, and the same lifted up, the knife being passed round the edges of the negative. The two gelatine films may then be removed in close contact from the paper.

A large number of examples was passed round, and an interesting discussion ensued.

#### PHOTOGRAPHIC CLUB.

OCTOBER 18.—Mr. Walter D. Welford in the chair.

The nomination of officers and notices of motion for the annual meeting, having been made,

Mr. F. A. BRIDGE showed a sheet of albumenised paper which was so very badly marked as to render it useless for printing. The makers had informed him that the fact that the paper had been albumenised in the spring would account for the defect named.

The Club, however, was of opinion that the marks were caused through carelessness in handling during albumenising or sensitising, and that

"The eggs that are laid in the spring, tra-la,  
Have nothing to do with the case."

The HON. SECRETARY read a telegram from Mr. W. Thomas, expressing his regret that he could not attend the Club to read his promised paper, as he was ill in bed with a bad cold.

The Club expressed its sympathy with Mr. Thomas, regretting at the same time the opportunity it had lost of listening to his expected paper.

Mr. STRETTON asked what was the experience of members as to self-toning paper, and whether there was really any gold in it. He had himself tried a certain brand of this kind of paper, and he got fairly good results. The prints had a decidedly toned appearance after being fixed.

Mr. MASON corroborated this statement, his experience having been the same. He thought it advisable to soak the prints in water before fixing them, and it transpired that this had a decided effect on the eventual colour of the prints.

**North Middlesex Photographic Society.**—October 16, Mr. F. W. Cox in the chair.—Mr. H. W. BENNETT, F.R.S., gave a lecture on

#### ENLARGED NEGATIVES.

He first dwelt on the advantages of large-size photographs as compared with small, particularly if for exhibition. The quality of an enlarged photograph could not be compared to advantage, as a rule, with one taken direct to the same size, but the exposure was much less. He described the apparatus required, which was of simple design and all made by himself. A camera and single slide, large enough to take the enlarged negative, and a frame to hold the positive to be enlarged from, both sliding on a grooved board. The camera had no bellows, but a double thickness of black twill was used instead. The dark slide was made of a drawing board, with grooved strips of wood fastened round to take the negative and shutter, which could be made of ebonite or millboard. The frame for the transparency had a recess to hold the positive, and the space between it and the camera was covered over with a large focussing cloth. He gave formulae for finding the distances and exposure required for various sizes of enlargement. With regard to the positive, he found nothing gave better results than transparency plates, bearing in mind that a positive like a lantern slide was not required. Twice the exposure required for the latter is given, and very little bromide used in the developer, and there must be no clear glass in the positive. Better results were obtained by backing both the transparency and the enlarged negative, which could be made on an ordinary dry plate.

**Leeds Camera Club.**—October 18, Mr. W. J. Warren (President) in the chair.—A lecture, with limelight illustrations, was given by Dr. LLEWELLYN MORGAN, of Liverpool, on

#### SUMMER AND WINTER VISITS TO THE ENGLISH LAKES.

Starting from Windermere, the lecturer took his audience to Troutbeck village, showing its yew-trees, its simple form of church, but which in its essential features was admirably suited to its surroundings, and went down the brook past the Bobbin Mill over Windermere Lake. Hawkshead, High-low Tarn, and Upper Langdale Valley were in turn shown, as well as the Slaters' Bridge, built by primitive workers, beautiful in its form, and the admiration of architects of the present day. Continuing along the valley, many interesting features were pointed out, and at Ambleside the old mill was presented in its summer and winter garb. Leaving Ambleside, Rydal, with its memories of Wordsworth, and many beautiful views of Thirlmere were given, showing that, as time softens down modern encroachments, the natural beauties will be little interfered with. Over the hills the lecturer passed to Brotherswater and Ullswater, with a run to Haweswater, backing to Thirlmere, and so on to Derwentwater and Keswick. Many quaint and picturesque views of Keswick were given, and from here Buttermere and Crummock waters were visited, and the coast reached at Ravenglass. Continuing along the Duddon valley to Broughton, and with a short railway journey to Furness Abbey, the journey ceased. The lecture was in many respects a remarkable one. It was illustrated by over a hundred slides of fine technique and artistic rendering, such a series as probably have never been shown to a Leeds audience. The lakes, mountains, and passes are beautiful in summer, but when shown in their winter covering, by contrast they appear even more beautiful, and their magnificent grandeur more adequately appreciated. Dr. Morgan kept his audience enraptured throughout with his interesting and racy anecdotes, at one time full of mirth when dealing with his difficulties and the freaks of his camera, the too inquisitive onlookers, or the still more mystified cattle, all of whom would persist in taking any but the right position for artistic treatment; or when, with inimitable pathos, he gave some touching, yet sad, incident.

**Dundee and East of Scotland Photographic Association.**—October 12, first monthly meeting of the session, Professor Steggall (President) in the chair.—Mr. Vanessa C. Baird (Hon. Secretary and Treasurer) submitted the annual statement of accounts, which showed a balance in favour of the Association of 77. 19s. On the motion of Mr. Ogilvie, seconded by Mr. Hill, the accounts were adopted. Professor Steggall, in retiring from the presidency, said he was sorry to have to mention that during the past year there had been a large number of resignations owing to the imposition of a uniform subscription of 10s. Between forty and fifty members had been lost in this way, which reduced the strength of the Society very materially. He, however, hoped that during the coming session the members of the Society would do their best to keep together and support the Society as loyally as possible, and strive by every means in their power to increase its usefulness and membership. The balance-sheet was thoroughly satisfactory, and for this they owed a debt of gratitude to Mr. Baird, the Hon. Treasurer. They had not only wiped off an adverse balance of 54., but they had carried forward to next year's account almost 82., so that they had gained something like 132. on the year's work. He had now held the office of President for three years, and he had very much appreciated the confidence the members had shown him. It had always been a pleasure to him to take the chair, and he desired to thank the Society for their extremely hearty support towards him. Mr. W. F. Hill was thereafter elected President in room of Professor Steggall, who was heartily thanked for his past services. Messrs. W. H. Tittensor and William Salmond were appointed Vice-Presidents; Mr. Vanessa C. Baird, Hon. Secretary and Treasurer; Messrs. J. S. Lawson and William Bertie, Auditors; and Professor Steggall, Dr. Tulloch, and Messrs. Salmond, Kilgour, and Lamb, members of Council. Mr. Sandell, of the Sandell Films and Plates, Limited, thereafter gave a demonstration of the working of the Company's Perfect (multiple film) plates and films, for which he was heartily thanked.

#### FORTHCOMING EXHIBITIONS.

1899.

October 27-Nov. 4 ... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.

October 27-Nov. 11... Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.

„ 27-Nov. 19... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.

November 15-17 ..... Hackney Photographic Society. W. Selfe, 70, Paragon-road, Hackney, N.E.

„ 20-25 ..... Longton and District Photographic Society. Thomas Mottershead, 43, Stafford-street, Longton, Staffordshire.

„ 27-Dec. 18 American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.

December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

„ 11-Jan. 1900 Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.

„ 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.

1900.

January 29-31 ..... Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.

April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

THE following applications for Patents were made between October 9 and October 14, 1899:—

CAMERAS.—No. 20,338. "Improvements in or connected with Photographic Cameras." Complete specification. J. FLECK.

DAYLIGHT CHANGING.—No. 20,547. "Improvements in or relating to Photographic Apparatus particularly applicable to 'Daylight' Changing of a Series of Flat Sensitive Surfaces." A. L. ADAMS.

DARK-ROOM LAMP.—No. 20,549. "A Portable Electric Incandescent Coloured Lamp or Dark Lantern for Photographic Purposes." A. L. ADAMS.

PRINTING.—No. 20,643. "Process for Photographic Reproduction of Patterns, Designs, or Pictures on Fabrics and other suitable substances by the application of Mordants, Dyes, and the like." F. DORAMER.

CAMERAS.—No. 20,590. "Improvements in Photographic Cameras." W. PATTERSON.

CINEMATOGRAPHY.—No. 20,621. "An Improved Method of Projecting the Titles or Descriptions of Films used in Cinematographs or other Animated Photograph Machines." W. C. L. HOLLAND.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### FILM PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Your leader upon the future of film photography has interested me so much that I feel constrained to offer some remarks upon it. The writer considers that the want of satisfactory dark slides greatly handicaps films. But why use dark slides for films? Is not the roll-holder the appropriate instrument for a flexible support? The very flexibility that is such an advantage in the one is as great a disadvantage in the other. The dark slide is inherent to the use of glass plates, but not to films, for which it is in no way adapted. Moreover, the roll-holder method of carrying films enables the designer to give us unique conveniences altogether impossible if the films must be carried in dark slides. One has only to study carefully the designs of the various film cameras brought out of late years chiefly by the makers of the Kodak to see this.

But I suppose that the dark slide is thought necessary in order that a focussing screen may be used. And here again I might ask, Why use a focussing screen? (I am speaking of hand cameras which cause the chief demand for films). A focussing screen is chiefly useful for two

purposes (a) to arrange the picture that is to be taken; (b) to get a sharp focus. Well, as to the first, constant usage is every day making the photographer more apt to depend on the view-finder for this, and the results are quite satisfactory. The professional assuredly will stick to the focussing screen till necessity makes him dispense with it. Yet the marine work of such firms as Adamson, West, and Priestly, done under circumstances which preclude the use of the focussing screen shows no lowering of standard from that cause. What is true of marine work should also be true of landscape work where the focussing screen is possible. For architecture and portraiture the hand camera is scarcely adapted, but even here the want of a focussing screen in no way precludes from getting satisfactory results. The depth of definition of the lens is such that merely stopping down will give all possible sharpness when using a swing back or rising front. In the case of one  $\frac{1}{2}$ -plate hand camera a stop  $f.64$  will allow the sensitive surface to be tilted as much as  $20^\circ$  from the vertical. With regard to the other question of getting sharpness of definition there is even less to be said. A hand camera worth using is or ought to be focussed by a microscope by a trained optician working under the most favourable circumstances. The photographer in the field can scarcely hope to equal his results. With regard to objects within infinity the depth of definition is so great that very little practice is necessary with most people to estimate the distance with sufficient accuracy, and, if there is any doubt, a smaller stop will make sharpness certain.

And here I might remark on the tendency to use a hand camera that will be an omnium gatherum of everything common to stand camera and hand camera. It cannot be too strongly urged that the efficiency of a hand camera, as of all instruments or machines which are intended for constant use, is directly proportional to its simplicity and consequent ease of working. The most satisfactory and serviceable cameras are those in which everything not absolutely essential has been sacrificed for the sake of convenience in use. It is quite a fallacy to sacrifice a considerable proportion of the cost and convenience of a camera on some detail that will not be used in ninety per cent. of the pictures taken. I have often thought that it is by acting on such a principle as this that those makes of hand cameras which are so well known, and which stay with us year after year, have been designed. Many a camera has been put upon the market which would allow different kinds of plates, use of a focussing screen, double extension, &c., but how many of them remain as permanent landmarks in the hand-camera world as have done, e.g., the Kodak and the Frena? They may be appreciated by faddists, but the world at large wants the most convenient camera that will take the ninety per cent. of the pictures, not the inconvenient camera, specially designed with the idea of taking the other ten per cent., of which, as often as not, a large proportion are failures or unsatisfactory.

By, then, restricting the movements and capabilities of the hand camera to such as will enable us to take, with the utmost ease, the great majority of subjects we encounter, we not only get a more convenient camera, but also one of greater precision and certainty. The man who uses a Frena, for example, to take a picture will only have to do three things; the man who uses a hand camera fitted with dark slides, filled with different kinds of plates, focussing screen, focussing hood, &c., will have to think about, goodness knows, how many things, and who can say that he will get a result so much better as to reward him for all his trouble and the risk (never absent even in the most expert) he runs of getting no picture at all by forgetting some necessary movement. Life is too short for such multifarious manipulations, labour of love though they be.

The roll-holder, as adapted to the modern hand camera, such as the folding cartridge Kodak, and, more particularly, to the folding pocket Kodak, affords us very many advantages of portability, lightness, compactness, small cost (as compared with slides), and gives satisfactory results in the majority of the pictures the average hand camerist takes. It is foolish to sacrifice all this for the sake of being able to take, say, one out of ten pictures on an isochromatic plate or film, or for some other such reason.

But the writer of your leader seems to have altogether missed the one disability that handicaps rollable films more than anything else. I refer to the cost—three times that of plates. If a paper film is put on the market at a price something like that of bromide paper, and of as good quality, I can see no reason why (backed up by the numerous roll-holder cameras, which are every day almost being added to) it should not soon oust glass. Money governs most of our actions nowadays, and, if the photographer of to-day can get a serviceable film at from 6d. to 9d. for quarter-plate size, he will manage to forego the various advantages which plates offer, just as his predecessors gave up, first wet collodion for the more convenient dry plate, and then the high-priced dry plate for the cheap plate, until now most of us use the 1s. a dozen plates without the slightest qualms as to their quality, which, of course, never will be as good as the wet collodion of the old days.—I am, yours, &c., H. M.

#### THE LEVIATHAN SPECIALITIES.

To the Editors.

GENTLEMEN,—In the current number of THE BRITISH JOURNAL OF PHOTOGRAPHY we notice a Mr. Peterson inquires for the manufacturers or wholesale dealers of the Leviathan concentrated colours.

We are more than surprised that he has been so misinformed through the medium of your JOURNAL, we having been established for over forty years, and well known to be the proprietors of the trade mark "Leviathan."

We would request you to cause a correct statement to be published in your next issue. We, Joseph Levi & Co., 97, Hatton-garden, E.C., are the firm whose name should have been inserted.—We are, yours, &c.,  
JOSEPH LEVI & Co.

97, Hatton-garden, late 40, Fumival-street, Holborn, London,  
October 21, 1899.

#### CONVENTION BADGES.

To the Editors.

GENTLEMEN,—I shall be glad if you will allow me, through your columns, to inform members of the Photographic Convention who were unable to be present at the Gloucester meeting that I have a few badges remaining over, and, should any unwilling absentees desire to have them as a memento, I shall be pleased to gratify them as far as the limited supply will admit.

Thanking you in anticipation,—I am, yours, &c.,

F. A. BRIDGE, Hon. Secretary and Treasurer.  
East Lodge, Dalston-lane, London, N.E., October 23, 1899.

#### PHOTOGRAPHY AND THE WAR.

To the Editors.

GENTLEMEN,—I don't know whether you had received news of the storming of Impati Hill, near Glencoe, when your paragraph was written. If not, though we have no photographic representation of it, your reference to "another battle of Majuba Hill, with the defeat of our brother Boers" was a peculiarly happy one.—I am, yours, &c.,

SURGEON-LIEUT.-COLONEL.

#### THE PHOENIX HAND CAMERA.

To the Editors.

GENTLEMEN,—The short report of the showing of my new hand camera at the recent meeting of the Photographic Club would convey the impression that the method of using a reflector to throw the image on a full-sized ground glass is the distinctive feature of my camera.

Over thirty years ago Mr. Sutton invented and patented such a method, and I am very anxious that I should not be counted amongst the very numerous inventors of old photographic inventions. The special feature of the Phoenix is that the setting of the mirror into its  $45^\circ$  position, or the releasing of it from that position, changes the plate that has previously been exposed, and brings the next into the position for exposure, so that it is absolutely impossible to expose the same plate twice over, and thus also reduce the necessary movements to a minimum.—I am, yours, &c.,

S. D. McKELLEN.

Mill-street, Long Millgate, Manchester, October 24, 1899.

### Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPH REGISTERED:—

W. A. Crockett, The Market House, Taunton.—Photograph of employees of Taunton Manufacturing Co.

STAMPS; and many others.—In our next.

G. C. would like to know a good book on water and oil tinting.—A work on the subject is published by Messrs. Newman & Co., 2 Soho-square.

"A CONSTANT READER," who asks us some questions about development and lighting, is referred to our rule, printed in almost every number of the JOURNAL, against answering questions put by persons who withhold their names.

AMERICAN PLATES.—GEORGE OSBORNE. The brand of plates named is of American make, and there is no agent for them in London or elsewhere in England; consequently, if you want them, you will have to import them yourself.

ORTOL.—Mew writes: "I see that Mr. W. D. Welford is reported in last week's issue of the JOURNAL as mentioning the enormous latitude in exposure allowed by development with ortol. As one who has hitherto used only pyro, I shall be obliged if Mr. Welford will give the formula for ortol for both snap-shots and time exposures, giving the proportions of accelerator and restrainer."

**STAMP PORTRAITS.**—G. BRIMMEL asks: "Could you give me the address of a firm that does stamp portraits, as a customer of mine wants some, and I do not see any advertisements for such appearing now?"—Wells & Co., Southgate, N.

**LENS FOR INTERIORS.**—J. COX. Both the lenses are good, but we should recommend you to employ the one designated B for general work. But A would be better when a wide angle has to be included. Better buy both, as they are so cheap.

**FERRO-GALLATE PAPER.**—J. L. HODGSON says: "Can you give me instructions for preparing and use of ferro-gallate paper?"—A series of articles on the iron processes appeared in the JOURNAL a short time ago, commencing May 12 and continuing weekly. These give full instructions on the subject.

**PAPER FOR ENLARGEMENTS.**—S. BENNETT. The Velox and similar papers are too slow for enlarging upon with the lantern. Of course, they might be used with a very prolonged exposure, but we expect it would be a question of hours with paraffin as an illuminant, even for a small enlargement.

**PHOTOGRAPHIC FILMS.**—WEISE & Co., 1, Guildhall-chambers, Basinghall-street, E.C., ask: "Be kind enough to inform us of the manufacturers of photographic films."—In reply: If by "films" cut celluloid films are meant, then Messrs. Fitch, Fulwood's Rents; Austin Edwards, Warwick; and other firms manufacture them. But the question is somewhat vague.

**URANIUM TONING.**—H. A. AYLWARD says: "Will you kindly favour me with a good uranium toning bath for bromide prints? I used one some time ago (formula lost); got splendid tones, but, on immersing in water, the image and tone washed nearly out; is there anything to prevent this?"—Nitrate of uranium, 10 grains; ferricyanide of potassium, 10 grains; acetic acid, 5 drachms; water, 1 pint. Wash for a less time in order to avoid change.

**LANTERN SLIDES.**—C. A. S. The two lantern slides are far too dense to look well on the screen, also the lights are considerably veiled, which is fatal to a lantern slide. You would get far better results by using plates specially made for lantern slides than by using ordinary plates. Lantern plates are made that are quite rapid enough for reduction in the camera. Are you not aware of that fact? We imagine not from your letter.

**METALLIC SPOTS ON PRINTS.**—THOMAS BOWKER asks: "Can you tell me the cause of the small spots on the enclosed print. Some of them, you will notice, have quite a metallic appearance? The paper is a drawing-paper that I purchased at an artists' colourman's in this city. Some of the prints are, if anything, worse than the enclosed."—The spots are due to metallic particles in the paper. Paper may be excellent for drawing and yet be, like this, of no use for photographic purposes.

**IMPERFECT FIXATION.**—R. C. says: "Can you please tell me the reason for the appearance on this negative? It was not there at first, but came on after about a couple of dozen prints had been made from it. It is a publication picture, and I have several others that have gone in the same way; I am perfectly sure the negative was thoroughly washed."—The fault is that the negative was not properly fixed in the first instance. When that is the case, no amount of washing will prevent this trouble.

**UNEVEN TONING.**—N. J. BIGNOLD says: "Can you please account for the stains on the enclosed print? They could be seen before they were put into the hypo, but they became more pronounced while they were in it. They are on ———'s P.O.P. They were toned in the sulphocyanide bath of the usual strength. I have never had such an experience before with this paper."—Yes, we can account for it. The prints were not kept moving about while they were in the toning solution, and, consequently, they have toned unevenly. That's all; they are not stained.

**BAD TREATMENT.**—REMEDY writes: "In the spring I was engaged here as operator and retoucher at 38s. a week, for a year certain. Last week I received a fortnight's notice to leave, my employer telling me that he could not keep me on during the winter, as business then was always very bad. Cannot I hold him to his agreement?"—Yes, certainly, if you have a written agreement; but, we are sorry to say, you cannot unless you have. We regret to say that assistants are often served as you are by unscrupulous employers at the end of the season where there is no written agreement.

**REVERSING A FILM.**—G. G. says: "I shall be obliged if you will give me a reliable formula for reversing a film on to another glass that will not stretch and distort it in the manipulation? I might explain that I have copied several negatives containing four to eight views reverse way, for use with autocopyist, intending to make Christmas-card views of town. It is not a success, and I now wish to reverse the films the right way, and print them by photographic papers."—First, well harden the films in alum or formalin, then immerse them in very dilute hydrofluoric acid, six or eight drops to the ounce of water, the film will then leave the glass. If the film should expand, it may be brought to its original dimensions by immersing it in methylated spirit.

**VARIOUS.**—GWALLA asks: "1. Can you give me the address of some firm or firms that manufacture those cameras we often see in the fairs and at the seaside? The photograph is one and a half inches square on thin tin. They are taken and finished in about two minutes for about 6d. each. 2. Does it require some great skill in working the camera? Could an ordinary photographer work same with little practice? 3. I have exposed some half-plates outdoor (extra rapid). I get details well, but lacking in density. I think it is under-exposure. No softness, but rather hard printing."—1. Mr. Nievsky, Avenue-road, Shepherd's Bush, W.; or, Fallowfield, Charing Cross-road, W.C. 2. Yes, certainly. 3. Probably the plates are under-exposed, but without seeing the negatives we cannot give a definite opinion. Possibly it may be the fault of the development.

**BOOKS ON PHOTOGRAPHY.**—GUILD says: "About a fortnight ago I wrote asking information as to the best books to get on the history and development of photography, so that I could write a paper (entertaining and instructive) for our young people's guild. In your issue of the 13th you promised my answer in the next week's paper. I have looked through last week's issue, and cannot see any reference to my query. I presume it has slipped your memory. I shall be very glad if you can oblige me this week."—In reply: If our correspondent will consult page 656 of our issue for October 13, he will find his query duly answered.

**FORMULA WANTED.**—MRS. G. B. HARKNESS writes: "1. Would you kindly supply me with the formula for the ferro-prussiate or blue print process, as I cannot remember the proportions? 2. I should be glad to know when THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1900 will be out, as I desire to procure a copy at the earliest opportunity; and whether it is possible to still get a copy of the 1899 edition, as it has got very torn!"—In reply: 1. In the JOURNAL for May 12, 19, 26, June 2 and 9 last a series of articles on iron printing was published. These we recommend our correspondent to procure. 2. The ALMANAC for 1900 will be ready in December. The 1899 edition is out of print.

**VARIOUS.**—OPERATOR says: "1. Recently I have been troubled with plates frilling to a shocking degree, and have tried common alum, chrome alum, and formalin. The latter has failed to act at all, and the first two produce markings which are unaccountable to me, especially the former. These patches take considerably longer to fix than remainder of plate, and, if any further doctoring (such as reducing) is required, the reducer refuses to act on these parts. What is the cause of the patches, and why does formalin fail to act in my hands? 2. At this time of year I am much troubled by sitters coming when there is practically no light. Will you be good enough to acquaint me of an artificial light which would not run into a great expense to have fitted up, easy to manipulate, sufficiently rapid to take children in not more than a second, and not require a lot of attention like magnesium; in fact, a good, quick, steady light which would enable me to take many sitters in a short time, and give short exposures whenever necessary? I should like a very clear answer to this, and full information as to how and where I can gather full particulars as to prices, &c. 3. Please name a good, cheap, and simply written book on the photographic lens, and where obtained. I have unfortunately forgotten all the algebra I learnt, and therefore prefer simple, understandable reading. 4. I use the pyro-soda developer and am much annoyed with the unsightly stain on fingers. I have no faith in finger-stalls, as they are clumsy, and are useless when punctured. What acid or other treatment is best to use to keep a pair of respectable-looking hands? I have tried nearly everything with only partial success. 5. I make up my pyro thus: soda sulphite, 8 ounces; bromide of potassium, 80 grains; sulphurous acid, 30 drops; water, 80 ounces; and pyro, 1 ounce. Why should this rapidly deteriorate and get badly discoloured in a few days?"—In reply: 1. The alum is not sufficiently washed out of the film before the plates are fixed—that is the cause of the patches. We cannot say why formalin does not act in your hands. It answers well with others. 2. The only light that will answer the mentioned requirements is the electric light. Write Messrs. Gwynne & Co., Brook-street, Holborn, or Messrs. Adamson & Co., Dashwood House, 9, New Broad-street, E.C. 3. Taylor's *Optics of Photography* (Whittaker & Co.). 4. See page 972 of the ALMANAC. 5. The solution should keep well. Possibly the sulphite of soda is at fault, or the water impure.

C. K. T. asks the following sixteen queries: "1. Why does not some maker bring out a hand camera for roll for 100 or 200 exposures with tube and ball release, arranged so that the pressure of the ball makes exposure, and on rebound brings new film into place, these two motions both following from one pressure of the ball, the result being that, at an event, exposures could be made quickly following one another? 2. What are the conditions for the certain result in using cold gum dammar and benzole varnish? Although the solution is decanted quite clear, the result is occasionally right, and oftener matt, fatal to lantern slides. If varnish and plate are warmed, result is improved. 3. In the ALMANAC there are plenty of formulae on retouching varnishes and negative varnishes, but none for transparencies and lantern slides. 4. In the formula the proportion of hypo to water for fixing gelatine plates is not given. 5. There is no formula for amidol to develop bromide papers. 6. Proportion of dammar to benzole is not stated on pages 1054-5. 7. Page 1055, wet process; what is the pyroxyline best suited for? 8. Can you give a formula for collodion for black-and-white work, also pyroxyline for ditto, and developer for ditto? 9. Hypo fixing for wet plates? 10. Water varnish for wet plates used when plate is wet after fixing? 11. Is there anything new about Cowan & Iles's idea for borders to lantern pictures (see page 839)? 12. What is their address? 13. What is the highest-power arc light that can be used in projection under the most favourable conditions for the arc, say ten-inch condensers (triple) and large lantern? at present it appears only to be 20 amperes and 80 to 100 volts (see page 953). 14. Is there any arrangement for the lecturer to press the button and automatically change the slide? 15. If there are several plans, could you describe them? 16. Can you get up another limelight jet competition to find the jet giving most light with least gas?"—Reply: 1. This query had better be referred to the makers of the apparatus. 2. Make the film thoroughly dry before varnishing. 3. The same will do for both. 4. We thought every one knew that about four ounces to the pint was what is used. 5. One will be given in the next. 6. Try thirty grains to the ounce. 7. Collodion for the wet-plate process. 8. The wet-plate process as given. 9. Same as for dry plates. 10. Not so good as spirit varnish. 11. Yes. 12. Chase Side, Southgate, N. 13. We cannot say; it is almost unlimited with suitable arrangements. 14 and 15. Not that we are aware of. 16. We have no intention of doing so.

## EX CATHEDRÂ.

THE *Strand Magazine* for November should be of especial interest to all photographers, for it contains a readable paper by Sir Robert Ball on "Great Showers of Shooting Stars," suggested by the approaching meteoric flight timed to occur between the 14th and 16th of the present month. Sir Robert refers in a readable manner to the peculiar characteristics of these interesting phenomena. In another part of this week's JOURNAL we reprint a paper by Professor Pickering, of Harvard University, dealing with the photography of the subject, which we commend to the notice of those of our readers who intend pointing their cameras towards the sky at the time when the meteors are expected to appear.

\* \* \*

SIR ROBERT gives, in the *Strand*, a graphic account of his observations of the display of shooting stars in November, 1866, but it is to Professor Lewis Swift, of Lowe Observatory, California, that we are indebted for some impressions of the shower which took place in the year 1833. This shower, says the Professor, far surpassed the others, if not all that history

records, in the brightness and number of the meteors seen. Professor Swift adds: "I was a boy not yet fourteen years of age, but the memory of that, awful night clings tenaciously to me yet. I am not going to even attempt to describe the wondrous scene, for the most gifted pen would fall far short in describing it. They fell like flakes of fiery snow in a moderate snow storm. It is estimated that at least 200,000 were seen from any one point, and this all the way from Greenland to Patagonia. I noticed that they appeared all over the sky, bright and faint, with short and long train, but was too young to observe it scientifically, and failed to notice that the trails, if traced backward, would meet at a certain place like the spokes of a wheel. Not one was seen to reach the earth, though many were very bright. The sky was perfectly clear, and the moon absent. It was a rain storm without a cloud, lightning without thunder. What made the deepest impression on my youthful mind was the deathlike silence above and around me. Seeing such a display of energy going on, and hearing no noise, the silence was as depressing and solemn as in a room of the dead."

\* \* \*

WE are informed that some time ago an application was put in at the Trade Marks Office for the registration of the word "Pakko" as a general name for photographic papers. This has now been refused by the Registrar on account of its similarity to existing names. Kodak, Limited, opposed the application on the ground of the likeness of the word Pakko to the well-known Eastman papers, Nikko and Dekko, and because the word could very easily be transposed into "Kopak," and this opposition has been upheld. The application for the registration of the word "Pakko" was made in all the photographic classes, namely, Nos. 1, 8, 15, and 39, and was refused in all. Similarly the application to register the word "Simplicio" for a photographic paper has been withdrawn in view of the opposition on the part of Kodak, Limited, the word "Simplicio" being likely to cause confusion with the registered trade mark, "Solio."

\* \* \*

THAT the advisability of securing photographic records of matters of interest is now acknowledged was shown at the last

Council Meeting of the National Photographic Record Association, when it was announced that societies were now at work in Warwickshire, Somersetshire, Leicestershire, Rutland, Rotherham, Birkenhead, and that the work had been taken up at Croydon, Redhill, Herefordshire, and other districts. 100 prints were presented by the President, Sir J. Benjamin Stone, M.P., of matters of interest in Lincoln, Shrewsbury, the Rock dwellings in Staffordshire, &c.; by Mr. T. W. Sharp, of some valuable records of the excavations now being carried on near Glossop; by Mr. P. Rudge, of some of the old crosses at Iona; by Mr. E. Scamell, old houses in the Strand, &c.; and by the Hon. Secretary, Mr. George Scamell, of various old churches at South Mimms, Pinner, Aldenham, &c., and of a series of views of Christ's Hospital.

\* \* \*

At a recent meeting of one of the London photographic societies a member is reported to have expressed "surprise that photographic chemists had done so little to place methods of combined toning and fixing upon a scientific and definite basis. A perfect understanding of these methods was a thing to which he looked forward with a keen interest, and he hoped that some steps would soon be taken to compass the end he had in view." One would have thought that little remained to be said on that subject by chemists. It was duly investigated by Hardwich more than forty years ago, and again by modern photographic chemists, Bothamley and others, since the system of toning and fixing has been reintroduced, also many articles on it have from time to time appeared in our columns. Evidently the gentleman who made the above remarks is not a very diligent reader of photographic literature.

\* \* \*

We may say that all the investigations made by chemists ancient and modern, prove that the system of combined toning and fixing is a very undesirable proceeding, as regards the permanency of the prints, unless certain conditions are carefully carried out. These, unfortunately, are too often ignored by workers, either with the view to economy or saving of trouble. The latter appears to have been uppermost in the mind of the gentleman who brought the matter forward at the meeting just referred to. We are sorry to observe an increasing tendency at the present time to save trouble, often quite regardless of the after-consequences, particularly amongst amateurs, notwithstanding that everything is now supplied by the manufacturers ready for use. How different from the time when the users, whether professional or amateur, had to prepare everything for themselves! It would be interesting to know how many amateur photographers there would be at the present time if that condition of thing now existed. Not more than there were a quarter of a century ago, we trow.

\* \* \*

THE County Council has been stayed, for a time at least with regard to Rutty's House in the Bromley Recreation Ground. In the report of the Council's meeting last week, the Parks Committee recommended that the house should be cleared away. In the discussion on the subject, one of the Council pointed out that the house was an interesting specimen of the period of William and Mary, and said that the Council's register of historic buildings should be, if that house was demolished, a register of historic houses to be demolished (hear, hear), adding that, if they took away that house, they would take away the last building of interest in the district,

and leave nothing but the shoddy over it. This remark was again greeted with hear, hear. Finally he said the only use the Parks Committee seemed to think ground could be put to was either for a bandstand or a gymnasium. Another Councillor said that the real name of the house was Tudor House, and that it was in good condition till it came into the hands of the Parks Committee. In the result, by a vote of 60 to 41, the Parks Committee had their recommendation referred back for reconsideration. Hence Tudor House is not to be demolished just at present.

\* \* \*

VANDALISM seems to be a rather prevailing idea with the County Council as at present constituted, but it must be borne in mind that, in some crowded neighbourhoods, ancient buildings, though of high historical interest, "cumber the earth," and their removal becomes a necessity in order to make room for far more utilitarian edifices; but this certainly does not apply to Rutty's House in the Bromley Recreation Ground, as it only occupies a small space in it. Particularly is this the case when it is considered that the Vicar of Bromley has offered to rent the house for a branch of the University Settlement, an excellent purpose to put it to. Vandalism, as we have just said, seems to be rampant with a certain section of the County Council, and we all remember how it was proposed some little time back to despoil Hampstead Heath, the most beautiful spot within many miles of London, by laying it out with the Council's symmetrical, orthodox gravel paths until it was prevented by the opposition of the public generally.

\* \* \*

WITH reference to our paragraph on the work of the Photographic Record Association it seems a pity that, as the older and interesting portions of London are so fast disappearing, metropolitan photographers do not keep the thing more in mind than they do, and secure photographs while the places are intact. Often the buildings are in the course of demolition, or scaffolding is in course of erection preparatory to it, before they are aware of the fact. Hence many pictures are lost, or have to be taken with the condemned buildings disguised with posters and hoardings.

\* \* \*

At the Mansion House Police-court, one day last week, a man was summoned for carrying a notice by way of advertisement on a motor car. The car, it appeared, belonged to a firm of "tipsters," and contained a notice-board advertising —'s "finals." There was also a wreath of ivy with the word "Irish" round it, symbolical of the tip for a race that day, and it was employed to deliver the finals at the different offices of the company. The solicitor for the defence contended that the car was not an advertisement within the meaning of the Act, but was simply employed for business purposes, delivering the tips, and put in photographs of it to prove his contention. The photographs, however, did not help his case in this instance, for in the end Sir Horatio Davies, who presided, inflicted a fine of 5s. and costs. This is the first time that we remember photography being utilised in defence of a case of this kind. We strongly suspect that it would have told better if it had been employed as evidence for the prosecution. Possibly it may be in similar cases in the future.

\* \* \*

WE are glad to note that the Society for Checking Abuses of Public Advertising is having considerable success. The

Building Act Committee of the London County Council have recommended the prohibition of offensive signs, and in many places the Society has obtained the concessions it desired. The North Eastern Railway Company has commenced to remove some advertisements which were considered unsatisfactory.

### ATMOSPHERE

"PLAYS in its time many parts," many of them closely applicable to photography or photographic techniques; and just as we observe, when reading the meteorological forecasts in the daily papers, if photographers do read them, the varying conditions of the weather in different localities, usually wishing it different for our own district, so do we find the atmosphere more or less to our mind as it dwells upon photography either ethical or technical. Thus we have the moral atmosphere, the utter absence of which in some of the advertisements in the "Wanted" column was recently violently inveighed against by a correspondent who is justifiably severe on the "open scandal" of advertisements for "specimens for show-cases." Then there is the "atmosphere of doubt," which too often envelops us when the tyro, with only a month or two's experience, exhibits a magnificent enlargement "entirely my own." Then, again, there is the atmosphere of the Salon, of Egyptian Hall notoriety; but, as we always desire to preserve a healthy tone in our artistic perceptions, our tendency is usually to free ourselves of its influence as quickly as possible. Hence we would at once abandon the abstract, and apply ourselves to the concrete. In doing this we are reminded of a purely physical aspect of the atmosphere which was lately suggested to us.

A very mysterious discolouration of several batches of P.O.P. was recently brought to our notice. The first batch so discoloured, after being only a month on stock, was indignantly returned to the manufacturers, who, dealing with an old customer, exchanged it for a fresh supply. When, however, the same complaint was made against the substituted batch, they declined to recognise the justice of the complaint. Very angry, the photographer gave his custom to a rival firm, but, when his new supply exhibited the same objectionable tendency, our intervention was solicited. Not to make too long a story of the matter, we may narrate the sequel—not arrived at without considerable trouble. All these batches of paper had been kept in a dry, cool cupboard, which had been used for years for the same purpose, and so might be considered free from suspicion. Yet the evil arose from no other direction. The cupboard was situated in a recess in a wall that separated the room from another in which waste hypo was kept, and which was precipitated every few days by the usual liver of sulphur method. Careless printers had so slopped the hypo about that it had soaked into the wall, and disintegrated the mortar to such an extent that some of the bricks fell out, and this, happening behind the residue vats, remained unnoticed from the printer's side, and, being close to the floor, was invisible from the cupboard side. It will be readily seen that sulphuretted fumes would be given off whenever the oil liquid was drawn off, and would diffuse into the cupboard, pass into the P.O.P. store, and naturally discolour it.

We do not suppose that a similar accident is likely to occur elsewhere, but the whole affair is such a valuable object-lesson that the manufacturer of paper or plates should not be too readily blamed for supposed imperfections. No doubt they

could tell us many a similar story of injured innocence. It is not twelve months since we were witness of such a case where plates were returned owing to sulphuration of the surface. Here the case was simple enough—another cupboard for storage, but of such a size that, after long use otherwise, it was determined to light it up with gas. Being a cupboard, with little ventilation, the products of combustion remained a long time in the place, and it can easily be seen that the slight amount of sulphur compounds that are thrown into the atmosphere when some of even the best kinds of coal gas are burnt would inevitably diffuse through the box and coverings of the plates, and as inevitably produce the familiar iridescence upon developing.

Here we may note that it does not appear to be generally known how to get rid of this annoying defect. It can be done with perfect ease, and care being taken, without injury to the negative by flowing it over, when all the hypo is washed out, with a solution of ferridcyanide of potassium of about two per cent. strength. We may point out, too, that this remedy is equally efficacious for the removal of green fog. It must be understood that we are not referring to the Howard-Farmer reducer, though the principle of action is analogous in some respects, for no hypo whatever is to be used except in cases where the image is almost hidden by the iridescent or the green-fog stain.

We are arriving at a time of the year when the atmosphere exhibits another aspect of a troublesome nature. Mr. Cadett recently pointed out how many workers objected to thick films on account of the slowness of fixing in the hypo. There is, however, no doubt that some of the best plates in the market have thick films, and we know many first-rate photographers who will not look at a thinly coated plate. With such plates slow fixing is concurrent with slow drying, and at this season of the year, unless a good supply of artificial heat is available, the atmosphere is often, through cooler temperature and increased hygrometrical condition, incapable of taking up the moisture from the plates, with the effect that occasionally they may take almost a couple of days to dry. Where speedy drying is important, the plates should be wiped both on film and glass side to get rid of all the moisture possible to throw as little work on the atmosphere as possible. In this connexion we may say that a correspondent speaks most highly of an electric fan which he has had fitted up for drying purposes.

We had intended referring to the atmosphere from a pictorial standpoint; but, as already our article is unduly expanded, we must leave that aspect for treatment on some future occasion.

**X-Ray Notes.**—At a recent meeting of the Paris Academy of Sciences, MM. Abel Buquet and Victor Chabaud gave a description of a new vacuum tube they had devised for preventing the anticathode from getting heated, this being an effect which, as is well known, greatly interferes with radiographic work. Their method is to fuse the platinum tube forming the anticathode directly to the glass, and to keep it cool by surrounding it with cold water. This is very probably the tube advertised and illustrated by Messrs. Isenthal, Potzler, & Co., the water and the platinum being enclosed in a kind of secondary bulb fused to the main bulb. Such an instrument should be exceedingly useful when using the powerful currents rendered available by the Wehnelt electrolytic break, though it is rather singular to find, as we have done, two expert workers holding diametrically opposite views as to the heating of the anticathode. One informed us that he always worked with the platinum red hot, while the practice of the second was to keep it quite cool by making the contact-breaker work so slowly that its beats could almost be counted.

**A New Metal.**—We have already brought before our readers the discovery of two new metals, polonium and radium, which possess the most extraordinary radiating power, very many times more intense than the uranium ore from which they are extracted, and now we learn that, at the meeting above referred to, M. A. Debiérne described still another metal which he had isolated from pitchblende, and which possessed a radio-active intensity 100,000 times stronger than that of uranium. The new metal, which, by the bye, has not yet received a name, resembles titanium very closely, and is not spontaneously luminous. The rays are capable of acting upon dry plates, and exciting the platino-cyanide of barium screen.

**Tele-photography.**—The popularisation of any new scientific instrument is often signalised by the publication of an article upon it in one or other of the popular magazines of the day. This we note has been done with regard to the tele-photographic lens in *Scribner's Magazine*, a series of photographs by Mr. D. L. Elmendorf being reproduced. They exhibit a wide range of experience, from Jungfrau within a few hundred miles from us to Popocatepec at the other side of the globe. There is little doubt that when the instrument is better known it will become of far more common use; for though it is justly said that, in this country at any rate, the atmosphere is not often clear enough to take photographs of objects many miles away, the lens is most usefully available for comparatively near objects which it is required to photograph on a far larger scale than other existing lenses are capable of achieving.

**Photographing the November Meteor Shower.**—The Meteor Section of the British Astronomical Association asks its members who wish to take part in the photographic observation of the November meteors to send in, without delay, their names, with full particulars of their photographic equipment to the Director of the Section, Mr. R. Wilding, F.R.A.S., Swillbrook House, Burke, near Preston, Lancashire. We have no doubt he would welcome efficient aid from readers not members of the Association who would like to join in the work.

**Peculiarities of Indiarubber.**—*Engineering* recently had an interesting review of some of the properties of indiarubber which will appeal to some of our readers. Any one who has had occasion to use indiarubber gloves or mittens to preserve the fingers from the injurious action of chemicals—bichromate of potassium, &c.—and has laid them aside for a while, knows how frequently they have become “perished” and useless, while when kept in constant use they seem almost everlasting. Some clue to the cause of this is given in the article. The sulphur used for vulcanising absorbs oxygen from the air, becoming converted into sulphuric acid, and this is known to be injurious to rubber. Naturally, when the gloves are in use, any acid formed is taken up directly by the liquids the gloves are immersed in. A plan often recommended for storing such articles when not in use is to keep them immersed in ammonia water. We cannot yet speak from personal experience of the efficiency of the plan, but we do know something to effect the purpose in view is highly desirable, for, quite recently an accident having happened to a pair we had had in use for some years, we took from a drawer a second perfectly new pair, which we had kept by us ready for an emergency. The first glove we put on tore in two pieces in the mere act of drawing it on!

**Another Royal Picture from Photographs.**—The German Emperor William has commissioned a German artist, Professor Knockfuss, to paint a large picture of their Majesties' ceremonial entrance into Jerusalem last year. We read that all the members of their suites that were present on this occasion have been photographed in the large court of the Foreign Office at Berlin. The artist will therefore have photographs of all the persons to work from so that the likenesses may be preserved. It will be interesting to learn if he will also have photographs of the surroundings, the gates, &c., to help him in his work; also, if this is the case, whether

they were taken before the event or at the time, because we read that, before the visit, the gates were renovated and embellished and somewhat modernised, as has been done on other occasions on important visits to Jerusalem, so that the gates, we are told, are widely different from what they were originally, and more is the pity. If the picture is painted from photographs taken at the time of the visit, it will not depict the gates, &c., as they are shown in photographs of them as they originally were, and there are plenty of them in existence.

### JOTTINGS.

WAR on a scale as large as that now being waged against our Brother Boers makes busy other people besides steamship companies, army contractors, and the usual furnishers of those supplies which a great movement of troops always renders necessary. The photographic trade and professional photographers have had their share of the money that has been publicly and privately spent during the past weeks in connexion with the present campaign. I have heard in the trade that very large orders for apparatus and material have been executed for South Africa; and several London and country photographers have told me that they have been called upon to produce great numbers of portraits of officers and men going out to the war—and of the girls they are leaving behind them. No doubt a great deal of photography will be done on the battlefields and whilst General Buller is completing the work of subjugation, annexation, or whatever is to follow the victory of the British arms; and thus the home trade may be expected to be kept busy for a considerable time to come. It is an ill wind that blows nobody any good! I suppose the Crimean War was the last occasion when so many troops left this country; but in those days photography had barely emerged from the Daguerreotype stage into that of the wet collodion, and could not have been utilised to the extent which is possible to-day. There were no hand cameras, highly sensitive gelatine plates; rapid shutters, pocket Kodaks, or cinematographs in the “early fifties.”

Those readers of the JOURNAL who passed over the Society news published on October 13 missed an item of great curiosity and interest. On page 654 the President of the Cornish Camera Club is reported to have suggested that members should investigate in the coming year “the curious fact that, given the same material and circumstances, one man could get good results, while another man got only unsatisfactory results.” No more novel subject could be suggested for a Society discussion, and besides the element of novelty it also possesses that of fecundity, for you could include in the discussion such items as heredity, individuality, opportunity, application, and the many other influences which unite to make one man different from another; and then, when the matter had been thrashed out to its uttermost how much wiser should we be? We have the fact before us that in all the main walks of life, let alone the little side-walk of photography, equal opportunity and (as far as it can be defined) equal ability do not make one man as successful as another. You can discuss the fact for centuries, but you will never alter it. After all, if everybody got equally good results in photography, how very monotonous photography would be, to be sure.

A few weeks ago I drew attention to the fact that the editor of the *Photo-American* had published an attack on the qualities of British-made photographic apparatus, which he erroneously suggested was inferior to the American productions. Since then he has indulged in a further outbreak of Anglophobia, the nature of which can be seen by the following extract: “All, or nearly all, of the English photographic journals have announced that the owner of the *Shamrock* has taken a camera to this country to secure views of the yacht race, and, oh, delicious morsel! how it has been mouthed and tasted over and over, the plates are to be sent back to England, in order to obtain the best results. If the Britons can develop plates better than we (which, of course, I am perfectly willing to wager they cannot), they are not living up to their reputation for generous and fair dealing in crowing so over Sir Thomas Lipton's decision in the matter. If they

suspect that they cannot, why, that's another matter, and no one will blame them for their wild, boyish enthusiasm over the fact that they can say a whole lot about it, any how. I've heard it said that the English people make a very great many *reversed negatives*."

The tone of this extract is not in the best of taste; and the whole deliverance is quite uncalled for, the "crowing" to which the writer refers being merely a figment of a too active imagination. I have met scores of travellers from America in this country who have brought American-made plates with them, and have preferred to develop them on their return home, in the hope or the belief that, by working amidst their accustomed surroundings, and with the developers most suited for the make of plate used, they would secure the best results. Nothing in the world could be more natural; but no British writer would say stupid things on that account. I do not suppose that a war between the United States and Great Britain will break out because I have called attention to the fact that an American journalist is "down" on British apparatus, plates, and developing abilities; but I suggest to the writer that his remarks do no credit to the common sense or dignity of American photographic journalism. Great Britain has sent a deal of money to the United States for photographic material in the last fifteen years, and, if American photographic journalists are incapable of being grateful for this, they might at least be civil.

Crooke *versus* Guerin is the title that might be given to a little controversy which lately made its appearance in the American journals. It may be remembered that, in his Presidential address to the Convention, Mr. Crooke expressed the weighty opinion that there is at present a marked appreciation of high-class pictorial portraiture, and that the men who produce it will be sought after. Almost simultaneously with the utterance of this opinion, the President of the American Convention, Mr. Guerin, was singling out for praise and recognition "the photograph entirely deficient in art principles, if it is only perfect in chemical and mechanical manipulations." In other words, the nominal, if temporary, head of American professional photographers was advocating the production of the "usual thing," the machine-made photograph of the show-case, in preference to work which relies upon its artistic or pictorial qualities for acceptance at the hands of the public.

According to a book of *American Photographic Studies* in my possession, and in which some of Mr. Guerin's work is reproduced, that gentleman is one of the most successful photographers of children in America. But Mr. Guerin's work, though pleasing and pretty, and probably remunerative to him, does not rise above the level of the usual thing. Most likely he is a man whose ideas on the possibilities of photographic portraiture were long since fixed beyond qualification or modification, and this condition of things operates to place him out of touch of modern tendencies. Even so, this does not lessen the force of his views, although it may discount them. It is not far short of a calamity that in these days a defence, if not a laudation, of the "usual thing" in photographic portraiture should emanate from a man who is placed in the position of guide and teacher of his younger brethren. Surely the mechanically perfect portrait is a false, if not a low, ideal to pursue; and, besides, is not the educated public, all the world over, showing an inclination to reject this sort of thing for work which is the outcome of a "more subtly suggestive style of treatment?" to borrow a phrase from that mine of quaint and curious remarks, the *Salon Forewords*.

Of the two photographic leaders—Crooke and Guerin—my money goes on Crooke. That kind of portrait photography which takes advantage of the illimitable resources of lighting and posing, of simple composition, and of the utmost capacity of the lens and dry plate for translating the characteristics and beauties of the human face and figure, the most delicate gradations of light, shade, and texture, and

calls in the best obtainable aid of the discreet retoucher and the photographic paper-maker—pictorial portraiture, in fact, is only just commencing to receive public notice and appreciation. The productions of such workers as Mendelssohn, Crooke, Barnett, Hollyer, Harold Baker, Histed, Fellows, Wilson, Joseph Thomson, Alice Hughes, and others I could name, are nothing like so popular or appreciated as they deserve to be, for the reason that the public at large has had little or no opportunity of knowing the kind of work these photographers produce. The great middle class has still to realise that "egg-shell" or "billiard-ball" portraiture is not the best that photography can do for them, while, as for the masses, they never see anything of a higher grade than the show-case three for-two-and-sixpence kind, and cannot therefore be expected to reason out portrait possibilities for themselves.

I am writing these lines as the result of a study of portrait photography in all the large towns of Great Britain. Where the very best work is shown, it always secures appreciation and patronage, provided those who produce it are men of business. I refuse to believe that an educated, art-loving public will long continue to accept the machine-made portrait which Mr. Guerin exalts, and which is so prominent in this country as well as his own. The public taste is ripe for something higher and better. The days of the usual thing in portraiture, I am convinced are coming to an end, but photographers require to be educated up to the possibilities of pictorial portraiture. I wish, in place of the one or two verbose and shallow-minded persons who stump the country with pictorial—i.e., landscape photography—for a text, it were possible to substitute one or two cultured and willing men, who could travel about opening the eyes of photographers as to what can be and is being done by the best men. Illustrated periodicals and exhibitions are perhaps having a strong salutary influence in the matter; but the spoken word and the illustrative example are far more potent in effect.

However, to descend from dreamland to workaday actualities: there is no doubt that a growing tendency towards better things in portraiture is manifesting itself in this country more and more as time goes on. Against the Guerin deliverance I will set a piece of advice which I lately heard a distinguished portrait photographer give to a young aspirant, "Study good pictures and try to produce something like them." Yes, there's the pith and marrow of the whole thing—study! I was much struck by the spirit of a rising photographic friend who lives 500 miles from London, and who recently spent a few days in London—the first time for years. Every minute he could spare, amidst the distractions of this great and gay city, he was "studying good pictures" in the National Gallery and elsewhere. And he is at home now trying to produce something like them. I am quite confident he will. COSMOS.

#### PHOTOGRAPHING THE NOVEMBER METEORS.

PROFESSOR W. H. PICKERING, of Harvard College publishes in the current number of *Popular Astronomy*, the following hints on taking photographs of the approaching star showers on November 14th—16th next:

The meteors may be photographed either with or without clock-work, the stars appearing either as dots or lines. There are three reasons why a camera may be advantageously attached to an equatorial mounting and driven by clockwork. First, many more stars will be photographed than if they are allowed to trail. Secondly, if the image of the star in the finder is occasionally examined, and the telescope adjusted so that round stellar images may be obtained, greater accuracy in right ascension will be secured. Thirdly, if the meteor photographed is not observed visually, that fact is of little consequence as far as a determination of the location of the radiant is concerned, if the instrument is provided with clockwork.

Since the radiant is constantly, although slowly, changing, it is

desirable, even with clockwork, to know the approximate time at which a meteor appeared. It is therefore recommended that the plate be changed at least as often as once an hour. Since the moon is nearly full, it is possible that still shorter exposures will be necessary, in order to avoid fogging the plate in case a portrait lens is employed. Another but less satisfactory remedy would be to stop down the lens. It is well to carry on visual observations at the same time including drawing the path of all meteors of the second magnitude or brighter appearing in the region covered by the map.

The camera should be attached to the outer end of the telescope tube instead of to its middle, as might at first seem more convenient, as otherwise the edges of the slit in the dome are liable to interfere with the view. If the slit is wide enough or an outdoor equatorial stand is available, several cameras may be attached to it pointing to different portions of the heavens.

In every case, however, the radiant should fall upon the plate. With two cameras it is recommended that the radiant should fall near the middle of the northern edge of one plate and near the middle of the southern edge of the other. With three cameras, two should photograph the region preceding the radiant, and one that following it, since early in the evening more meteors, which are nearer and therefore brighter, precede the radiant than follow it.

Since the ordinary bellows camera is only intended to be used in a horizontal position, its joints should be thoroughly braced before it is attached to the telescope, otherwise we shall find that the distance from the lens to the plate will vary with the altitude, throwing the images out of focus. In order to test the matter thoroughly, photographs should be taken at various altitudes with slight changes of focus several nights before the shower. A few long exposures should then be given at different altitudes on some point having the same declination as the radiant, in order to determine if the axis of the photographic lens remains at a fixed angle with that of the telescopic finder. This is a matter of the highest importance, and is very liable to give trouble unless the camera is firmly lashed to the telescope, and the finder is fitted securely. The plates should all be numbered in the corner, on the film side, with a soft lead pencil, or, better still, in copying ink.

If only a few meteors are photographed, as will be the case upon the nights immediately preceding and following the shower, it will be very difficult for any single observer to secure a satisfactory determination of the location of the radiant. By combining his results, however, with those obtained at other observatories, much more satisfactory results may be obtained. For this reason it is desired that all original negatives showing meteors taken during the present shower may be forwarded to this Observatory at its expense. They will then be examined, measured, and returned to the senders, if desired. If it is not practicable to forward the original negative, a glass contact print from it would be the next most desirable record, or a print upon a flexible film, which may be sent by mail.

A single bright meteor, if photographed from two or more stations suitably located, would furnish all the material necessary for a determination of the radiant. These stations might be, in general, from ten to forty miles apart. For photographic observations of parallax the lesser distance would probably prove the more satisfactory, and one station should be nearly north of the other.

We will now discuss the best method of photographing the meteors when an equatorial mounting driven by clockwork is not available for the support of the camera. It is thought that, if the following suggestions are carefully carried out, the results obtained will be but slightly less accurate than those secured by means of clockwork. They will certainly be far more reliable than those secured by the most skilful astronomer who trusts solely to visual observations.

The best lens to use for this work is undoubtedly a large, old-fashioned portrait lens, but it may well be supplemented by a wide-angle lens, the radiant being central in the field of each. A very convenient and simple form of camera consists merely of two rectangular wooden tubes, one sliding inside of the other.

These should be blackened upon the inside. The lens is attached to the outer tube, and a suitable frame to hold the plate-holder fastened to the inner one. If these tubes are well fitted, once they are properly focussed, four screws may be driven into them, holding them firmly together, and they will remain immovable, regardless of the angle they make with the horizon. A simple form of equatorial mounting consists in attaching the camera so as to point upward from a base, at a fixed angle of  $22^\circ$ , equal to the declination of the radiant. The base is pivoted to turn upon a board placed parallel to the equator. A series of holes, in any one of which a peg may be inserted, serves to adjust the angle in right ascension to any desired hour angle. By this device considerable time is saved in shifting and pointing the camera or cameras (*Harvard Observatory Annals*, vol. xli. p. 147). If a bellows camera is used alone without any accessory mounting, it had best be firmly attached to a board, which can be inclined against a box at a suitable angle.

The quickest method of focussing the camera is as follows: Focus by daylight on some distant object, mark the focus on the camera, push the lens in about two millimetres, and point on some bright star at night by sighting along the edge of the camera. Expose the lens for thirty seconds, and then, without moving the camera, lengthen the focus one millimetre. Expose again, and so on for five exposures. Let the last exposure have one minute duration to distinguish it from the others. On developing the plate, it is probable that nothing will be seen until it is finally fixed, and can be examined in a good light. Then five short lines will appear, due to the motion of the star in the heavens. The best focus can be interpolated from among them. It is well to point in some region of the heavens containing several bright stars, such as the constellation of Orion, for, since the focus varies in different portions of the plate, a better selection can thus be made.

Each time before exposing the camera, on the night of the shower, it should be set by sighting along its edge, so as to point at  $\epsilon$  Leonis. Owing to the motion of the stars, this will bring the radiant near the centre of the plate at the middle of the exposure.

On account of the length of the star trails, it is better that the exposure should not exceed one half hour in duration. The exposures should be closed exactly on the hour and half hour, which, allowing for the time required to change the plates, will make the exposures a little short of thirty minutes. A brief exposure of two seconds should be given just before and after the long exposure. The time of these exposures should be taken with the greatest care in hours, minutes, and seconds, and also the time that any bright meteor crosses the field of view of the lens, as the difference between these times gives the right ascension of the radiant. The course of the meteor should then be drawn as carefully as possible upon the circular map, and finally a description of it given as previously described.

The chief error affecting this method of observation consists in noting the time that the meteor crosses the field of view. This error may, it is found, readily amount to many seconds. By the use of a chronograph or a stop watch the difficulty is largely avoided. In default of those instruments, the error may be greatly reduced if an assistant will keep his eye steadily fixed upon his watch, while the observer fixes his on the sky. The instant a bright meteor is seen crossing the field of view of the lens the observer calls "tip," and the assistant records the time. Being relieved of the necessity of looking at the watch, the observer can, moreover, make his other records with much greater accuracy.

If but few meteors are seen, it will not be necessary to change the plate at each exposure. In the case of the wooden equatorial mounting, any slight inaccuracies in fixing the board parallel to the plane of the earth's equator will cause successive trails of the same star to deviate from one another. If the various exposures differ among themselves by ten or twenty seconds, the corresponding differences in the lengths of the star trails will be quite marked. There will therefore be no difficulty in determining which set of star trails correspond to the trail of the meteor. It is recommended, however, that not more than three or four meteor trails be allowed to fall upon any one plate.

## THE HISTORY OF OPTICAL GLASS.

[Translated from "The Theory and History of the Photographic Objective" by Dr. M. Von Rohr.]

THE manufacture of optical glass could only attain importance when, in consequence of the development of optics, telescopic objectives of greater dimensions were found to be a necessity. The most important step in this direction was the achromatising of telescopic objectives in which John Dollond succeeded in the year 1757. The two kinds of glass, crown and flint, which were now to be made in larger discs, offered great and separate difficulties in the art of melting, in so far as, towards the end of the last century, pieces of somewhat greater dimensions were obtainable from crown, but not from flint, glass. We may observe that the melting of optical glass differed in no way from that of ordinary glass, the whole proceeding consisting essentially in selecting the pieces fit for optical instruments from among those prepared for other trade purposes. Thus does G. Bontemps describe—and, in this instance, free from prejudice—the attempts made by the glass-manufacturer, D'Artigues, who supplied material to the optician, R. Cauchois.

By this method, however, but very small discs, 8–11 cm. (3 to 4 inches), were produced, and even these could not be guaranteed. The difficulties to be overcome in the production of comparatively thicker pieces as, for instance, the Chevalier prisms, have already been treated of in a former chapter.

The first who directed his attention to the making of specially optical, or, more correctly, flint glass, and thus paved the way for the necessary differentiation in the melting industry, was the watch-maker, Pierre Louis Guinand (born, 1748; died, February 13, 1824), of les Brenets, a little place on the French frontier, in the present canton of Neuchâtel. How this man happened to hit upon the idea of glass-melting, which lay so far out of his own department, and who, according to G. Bontemps, carried it on as a clever amateur without any technical knowledge, it is impossible to say. His attempts, which extend back to the year 1775, did not, however, prove very successful, as may be inferred from the communication of the optician, Rochette, and the astronomer, J. de Lalande, contained in a letter of Aimé Guinand, the son of P. L. Guinand.

According to this same source, negotiations began in 1804 with the Bavarian national economist, J. Utzschneider, by whom P. L. Guinand was invited to send samples of glass to Munich for examination, J. Utzschneider being in want of a capable technologist for the proposed enlargement of the Liebherr works, which he intended developing into a mathematical mechanical institute. Whatever the result of the examination was has remained unknown. In any case, a meeting of the two parties was arranged, and took place in Aarau between J. Utzschneider and the two Guinands, the former giving an order in January 1805 for a sample melting of flint glass at his own expense. The result of the examination of this and other glass ended in the removal, in September 1805, of Guinand to Benediktbeuren. In the two accounts to hand we meet with a contradiction in so far as J. Utzschneider, in his obituary on J. Fraunhofer, represents P. L. Guinand as a melter of limited ability, on whose engagement he had not definitely decided at the time of the meeting in Aarau. According to A. Guinand's account, his father's removal to Benediktbeuren took place entirely at J. Utzschneider's personal solicitations. However this may be, it was only in February 1807 that a contract, for the space of ten years, was closed with P. L. Guinand, by which he was to receive a fixed salary of 1600 florins in gold,\* and to live free of rent.

The interval, from the autumn of 1805, was filled up in the building of a glass manufactory and the preparation of preliminary meltings. By the terms of his agreement, P. L. Guinand had bound himself over to disclose his secret to J. Utzschneider, and to any person named by the latter. This secret, no doubt, consisted in the stirring of the crucible with a rod composed of crucible clay, though on this point we can give no positive affirmation, this artifice being looked upon as a trade secret, and no account of P. L. Guinand's acquirements, or of the improvements introduced by J. Fraunhofer appearing ever to have been published separately. The meltings at first carried on in J. Utzschneider's presence presented two deficiencies; the glass was full of striae and the refractive indices of the different pieces varied according to their position in the pot. Only by using carefully selected crown and flint pieces was it possible to supply the necessary objectives to measuring instruments, which were ready-made as far as the brasswork was concerned. We are therefore not surprised that this result did not come up to J. Utzschneider's expectations.

Meanwhile (in 1807) J. Utzschneider being again called into the service

\* Notwithstanding all my endeavours, I have been unable to ascertain the value of the sum in modern money, the standard of coinage in South Germany at that time being apparently unknown.

of the State, and no longer able to devote his whole attention to the glass manufactory, initiated J. Fraunhofer into the secret, and even intrusted him, in September 1811, with the task of producing flint glass in conjunction with P. L. Guinand. At the second melting J. Fraunhofer obtained glass free from striae and homogeneous through the entire pot, without, however, securing complete certainty, for later meltings were again unsuccessful. It was only two years afterwards when he discovered that, in order to guarantee good quality, he must use larger pots—of four, instead of two, hundredweight capacity.

Some time later (on December 6, 1813), P. L. Guinand gave notice to leave, and in the beginning of the next year, after a sojourn of eight and a half years, left Benediktbeuren, under the stipulation of abstaining from any active part in glass manufacture on payment of an annual compensation of 800 florins.\*

According to concurring accounts, he undertook the management of a new glass manufactory in 1816, thereby losing his compensation, but making an offer, as we are informed by J. Utzschneider, to return to Benediktbeuren, an offer, however, which was not accepted. In his glass works he produced, according to his son's testimony, discs for objectives of 33 and 35 cm. (13 to 13½ inches) diameter, which were bought by N. J. Lerebours and R. Cauchois. Later on he entered into correspondence with the London Astronomical Society, and also with the French Government; the negotiations, however, fell through, and P. L. Guinand died on February 13, 1824.

In Benediktbeuren J. Fraunhofer continued to work at the production of optical glass, and, according to J. Utzschneider, obtained better glass, and with more certain results, than P. L. Guinand had been able to do in 1814.

The largest telescope completed under J. Fraunhofer's supervision had a diameter of lens of 24.4 cm. (9.6 inches). The objective for the Bogenhausen telescope, with a diameter of 28.4 cm. (11.2 inches), was taken in hand during his lifetime, and the Merz firm, working upon his tested methods, found it possible later on to produce discs for objectives with an aperture of from 38.0 cm. (15 inches) to 43.4 cm. (17.1 inches).

But it would scarcely be fair to speak only of these successes concerning ordinary glass manufacture, J. Fraunhofer taking a far broader view of his task. Not content with having mastered the purely technical difficulties of ordinary glass-making, he originated the important idea of examining the influence exerted by the different components on the qualities of the ready-made glass.

In the first place, he tried to find out the connexion between the composition of the glasses and their liability to tarnish; and, in the second, he undertook the far more important task of systematically ascertaining the connexion between composition and optical qualities.

J. FRAUNHOFER'S GLASSES.

Kinds of Glass.	Refractive index for D.	Medium Dispersion $\nu = \frac{n-1}{\Delta n}$	$n-1$	Partial Dispersion.		
				B to D.	D to F.	F to G.
Crown glass No. 13	1.5290	0.00904	58.4	0.00367 0.406	0.00636 0.703	0.00557 0.616
Crown glass No. 9	1.5296	0.00920	57.6	0.00376 0.409	0.00647 0.703	0.00561 0.610
Crown glass Lit. M. (probably containing kali).....	1.5591	0.01081	51.7	0.00430 0.398	0.00767 0.710	0.00679 0.628
Flint glass No. 3	1.6085	0.01624	37.5	0.00645 0.397	0.01155 0.711	0.01073 0.661
Flint glass No. 30	1.6306	1.01799	35.0	0.00702 0.390	0.01288 0.716	0.01194 0.664

Flint glass No. 13 (probably borosilicate flint).....	1.6350	0.01858	34.2	0.00729 0.392	0.01322 0.712	0.01203 0.648

In this aim, too, J. Fraunhofer was quite original, inasmuch as previously to him no one had ever been able to give the optical properties of the different glasses in exact figures. It was through his method of

\* The value of this sum was just as impossible to ascertain as that of the salary. Not even the proportion between the florin proper and the florin in gold—neither one nor the other then being a coin, but a simple unit for calculation—could be established.

using the dark lines on the spectrum that refractive index and dispersion could be correctly measured, and it was due to the same method that the disproportionate increase of the dispersion in crown and flint glasses became a certainty. Being himself a practical optician, he was fully conscious of the importance of glasses with proportionate increase, and, aware of this quality in combinations formed of a glass and a certain liquid, he cherished the hope of melting glass pairs superior in this respect to the old crown and flint. In order to give an idea of his results, I subjoin a table of his glasses in the form afterwards used by E. Abbe and O. Schott.\*

The pair best agreeing was Crown Lit. M. and Flint No. 13. The reason for giving up these promising meltings is very likely to be found in their fatal liability to tarnish.

To these promising attempts—the production of the new glasses in larger meltings not having, as it seems been arrived at—the death of J. Fraunhofer in 1826 was fatal; they fell into oblivion. Neither J. Utzschneider nor G. Merz and F. J. Mahler were capable as yet of developing the work of the gifted deceased, and the process of glass-making remained simply in the state to which Fraunhofer had brought it for regular manufacture.

Before we come to speak of the further development of the art of glass-making, it will be advisable to cast a look back on the merits of the two above-mentioned men, which seems all the more necessary as the accounts to hand evince a great spirit of partisanship, A. Guinand and G. Bontemps taking part for P. L. Guinand, and J. Utzschneider siding with J. Fraunhofer. Added to this is the objectionable habit, so often to be met with in men of different nationality, that he who can most detract from the merits of his foreign opponent is looked upon as the better patriot. In this A. Guinand, anxious to ascribe the world-wide fame of J. Fraunhofer's Optical Institution to the labours of his father, goes to the extreme. However human this may be, we must most distinctly declare that the results of the co-operation of several men can by no means be attributed to one alone. We shall be doing justice to P. L. Guinand when we ascribe to him the very happy idea of the suitable stirring rod, but the development of the process by which the success of the melting might be reckoned upon with some certainty appears essentially due to J. Fraunhofer; in any case, A. Guinand does not credit his father with this ability. Concerning, however, the plan of methodically improving glass in respect to the lessening of the oxidising influences and the removal of the secondary spectrum, this, in so far as it succeeded at all, must be ascribed to J. Fraunhofer alone.

Coming now to the further development of the manufacture of glass, the scientific treatment, as already mentioned, disappeared with J. Fraunhofer's death. The Optical Institution carried on the technical work as before, providing glass, however, for its own needs or those of the Merz firm only, and appears not to have remained behind the foreign productions. How great an importance we must attach to J. Utzschneider's personal influence may be inferred from the fact mentioned by E. Voit that a competitive manufactory was founded in the very year of J. Utzschneider's death.

The latter died on January 31, 1840, from the results of an accident, and in the same year the Munich banker, Ruedorfer, in Kohlgrub, near Murnau, founded an Optical Institute, with glass works, in which the meltings were carried on under the supervision of a workman formerly in J. Fraunhofer's employment. This Institute did not remain long in existence, owing to the want of scientific assistance required for the computation of the lenses to be ground from the ready-made glass. The glass produced there was made use of, up to the fifties, by the Munich optician, Baader.

Here we may still mention the attempts of the mechanic, Körner, in Jena, who, under the patronage of the Grand Duke of Saxe-Weimar, tried to melt flint glass between the years 1826–46; but his endeavours, which were directed towards the melting of ordinary flint glass only, remained without result.

Also C. A. Steinheil, as A. Safarik, on M. Perty's authority, reports, had set himself the problem of melting glasses with proportionate increase of the dispersion. For this purpose he himself had spectrometrically examined the different sorts of optical glass, and succeeded in interesting the celebrated J. Liebig to take in hand the chemical analysis of the samples. He was hoping by simple calculation to find out the proportion of the components in order to arrive, within certain limits, at the prescribed variation of the dispersive power; but, concerning these attempts, nothing has been published.

Georg Merz and, after his death in 1867, his son, Sigmund, continued to a certain extent J. Fraunhofer's attempts to melt glasses with proportionate increase of the dispersion. S. Merz's meltings of 1868 showed the influence of the percentage of lead on the optical properties, and in 1882 his published account gave notice of the result that proportionate dispersion could be obtained by infusing the right amount of lead.

This is all that is known concerning the art of glass-melting in Germany in earlier days. Nearly everything relates to J. Fraunhofer or to his successors or zealous imitators. Manufactories for the making of optical glass only, which had nothing to do with the grinding of the lenses, appear nowhere to have been in existence.

Far different was the fate of J. Fraunhofer's art in foreign countries, and first of all in the French-speaking domain. After the death of P. L. Guinand the secret remained in the possession of his two sons, one of whom, probably the elder, was the above-mentioned Aimé. The two separated, the elder becoming proprietor of a glass manufactory in the neighbourhood of Neuchâtel, which was carried on later by his successor, Theodore Daguet, in Solothurn.

The younger son entered into connexion with G. Bontemps (one of the Directors of the glass manufactory of Choisy-le-Roy), and the Parisian optician, N. J. Lerebours, working in conjunction with them according to his father's method of process; but, the information he imparted being found insufficient, the connexion was dissolved. Upon this, according to Sh. Muspratt's statement, the technical director of the glass works, Thibeau deau was drawn into consultation, and at last, in the year 1829, their joint efforts resulted in the production of glass discs free from defects, of from 32.5 to 38 cm. (13 to 15 inches) diameter. From this time forth, relying on G. Bontemps' account, we are able to speak of a regular manufacture of optical glass in France. This was taken up first by G. Bontemps and then by P. L. Guinand's youngest son, who, upon his death in 1851, was again succeeded first by his son-in-law, and afterwards by his grandson, Ed. Feil. The Guinand method of procedure was published in 1840, almost contemporarily by G. Bontemps and the younger Guinand. Very probably the information given by Ch. Fabre (1892), "Guinand had introduced boracic acid into the glass in 1842," refers to the latter. But the kind of glass thus obtained does not appear to have been durable.

Later on, in 1848, G. Bontemps, finding himself politically compromised, and being obliged to resign his position, accepted an invitation from the firm of Chance Brothers to go to Birmingham. His removal thence now carried the art of glass-making into England, and the firm acquired a great reputation for optical glass; as a matter of fact, the growth on foreign ground of the Guinand-Fraunhofer art was very favourable in respect to its technical excellence, and we may safely say that photographic objectives, up to the more modern times, were exclusively prepared from French or English material.

The great success which during the period mentioned had attended the technical manufacture of glass in Benediktbeuren and the brilliant achievements of J. Fraunhofer in telescopic optics, had become known to a very wide circle and excited general sensation. This was all the more natural, the production of flint glass having been looked upon as a trade secret. In 1824 the London Astronomical Society appointed a commission to conduct an inquiry into the manufacture of flint-glass. This commission, whose members included J. F. W. Herschel, M. Faraday, G. Dollond, and P. M. Roget, arrived at the conclusion that the improvements necessary were rather of a mechanical than chemical nature, and in particular that freedom from striae could only be brought about by constant agitation of the mixture.

The leading spirit of this commission, however, M. Faraday, did not confine himself to this simply theoretical discovery, but busied himself, both in his own laboratory and in the glass manufactory, with the practical solution of the question, and, by making some changes in the chemical composition, came upon glass easily fusible, which therefore offered greater facilities for the constant agitation operation. This substance, of remarkable limpidity, was known under the name of Faraday's heavy glass, and proved very important in experiments connected with the polarisation of light by magnetic action, and is composed, according to Muspratt, of the following ingredients:—

Protoxide of lead .....	104 parts.
Silicate of lead .....	24 "
Dry boracic acid .....	25 "

The next improvement, made independently of the Guinand-Fraunhofer school, took place in France by the manufacturer Maës in Clichy, and was the production of zinc crown. The exact date of the discovery

\* To readers desirous of further information, we beg to refer to Mr. T. B. Dallmeyer's able paper in THE BRITISH JOURNAL OF PHOTOGRAPHY, 1890, p. 293.

is unknown, its first appearance seems to have been at the London Exhibition in 1851, where it was distinguished by a Council medal. It contained oxide of zinc and a certain percentage of borax or boracic acid, being colourless and homogeneous in the mass. From Ch. Chevalier's communications, we learn that this material was used for his photographic objectives. At the Exhibition more weight had been laid on the applicability of the new materials to telescopic objectives, and two plates of 11.4 cm. ( $\frac{4}{5}$  in.) and 17.8 cm. (7 in.), colourless and free from striae, were exposed for show.

Very interesting is the abstract given by Sh. Maspratt from the report of the Council Jury on Optical Glasses. In this abstract great attention is drawn to the importance which the attempt of Maës for the removal of the secondary spectrum has when zinc crown is used in the place of flint-glass, whilst the place of the crown is taken by a hypothetical glass "in which fluorine enters as a distinguishing ingredient, in combination with silica, aluminium, or other materials." Such hypothetical glasses, colourless and homogeneous, had been made in small quantities. Since this report of the 1851 jury nothing further has been heard of the matter, and it does not appear that this initiative of trying to obtain objectives with diminished secondary spectrum has been followed up.

After the Maës procedure, which seems to have been carried out on a large scale, the regular production of this glass being mentioned even as recently as 1856, only one new kind of glass, of French origin, is known to me, and of which notice is made in the year 1867. This glass was melted by the Parisian glass manufacturer Lamy; it was a heavy thallium flint glass of specific gravity, 4.18, and a refractive index,  $n_D = 1.673$  ( $n_B = 1.661$ ;  $n_H = 1.710$ ), and was of a yellow colour. Whether the same was ever brought into use, I am not able to say.

Thus we see that at the time when the production of optical glasses was in a flourishing condition, both in France and in England, the consciousness of the importance of new glasses had not been lying dormant. In France some such did appear, but it does not seem that the attempts were carried on in any systematic manner.

Not long after the death of J. Fraunhofer, an English clergyman, William Venable Vernon Harcourt (b. June, 1789; d. April, 1871), began attempts in glass-making. At first he could make but few meltings, owing to the hindrances which always offer themselves to experimental laboratory meltings. A fresh impulse, however, was given to his efforts by G. G. Stokes, whose acquaintance he made on the occasion of the 1862 meeting of the British Association at Cambridge. This *savant* had busied himself with researches on fluorescence, and therefore evinced great interest in W. V. V. Harcourt's work. Inquiries on fluorescence, which appear to have been taken into consideration were, however, soon dismissed in consequence of the greater importance attached to the examination of the spectrum. From this time attempts were systematically carried on, and in 166 different meltings a series of very different components was put to the test, in order to ascertain their influence on the increase of the dispersion through the different regions of the spectrum. Doubtless, it was all the more difficult to determine this influence, as W. V. V. Harcourt had not been successful in producing the smaller samples homogeneous, and therefore the striae contained in the prisms ground from the samples made exact measurements impossible. Nevertheless, placing reliance on their measurements, W. V. V. Harcourt and G. G. Stokes were in a position to lay down certain rules, for instance, that titanio acid lengthens the blue, whereas boracic acid extends the red end of the spectrum. The principal aim of their researches was J. Fraunhofer's old object of melting glass suitable for removing the secondary spectrum; they considered they had nearly attained their aim and produced—according to A. Safarik—two discs of titanio glass and two of terborate of 7.6 cm. (3 in.) diameter which were destined for a telescopic objective free from secondary spectrum. In grinding the lenses it was found necessary to cast aside one of the titanio discs and to grind in its stead a lens of ordinary crown glass. The objective thus composed was not faultless, but proved that it was possible to get rid of the secondary spectrum.

W. V. Harcourt's death, in April 1871, appears to have put an end to these efforts for production of new glasses.

The results published by G. G. Stokes underwent a critique by S. Czapeki of which I take advantage in the following. The English *savants* had correctly recognised the specific influence of boracic acid, whereas they were in error respecting their statement concerning titanio acid. On account of the inconvenience of working with silicates, arising from the difficulty of fusion and the pasty character of the fused glasses, W. V. Harcourt's experiments were chiefly carried on with phosphates the influence of which were looked upon as that of titanio acid.

W. V. Harcourt's work was not taken up in England to any great

degree; one attempt of titanio glass made by J. Hopkinson in the glass works of Messrs. Chance Bros. was unsuccessful, because, as we have already remarked, the titanio acid does not possess the specific influence ascribed to it.

That similar experiments were not further carried on either by the English firm or the French Swiss manufacturers, notwithstanding the publications by G. G. Stokes lay—as E. Abbe has pointed out—apparently in the fact that on the one side the risk was very great, and, on the other hand, the production of optical glass had become, so to speak, almost a monopoly, and therefore no absolute necessity existed for these firms to put themselves to any extraordinary trouble.

The necessity of applying perfectly new glasses, of which the principal virtue was not the proportionate increase of dispersion in crown and flint glass, but a new relation between the medium refraction and the medium dispersion, was, as far as the photographic objective was concerned, pointed out by L. Seidel in 1856, and by J. Petzval in 1857, yet the remarks of these two men seem to have been passed over without attracting any attention. In 1878 E. Abbe laid great stress upon the importance of new glasses for microscopic objectives, further improvements with the old kinds having been found impossible. This necessity in microscopic, as well as the long-felt want in telescopic optics, became paramount, and turned the attention afresh of wider circles to this question. Later on, the attempts undertaken at a previous period by H. Schroeder and A. Safarik were also made public.

The first named had begun to melt magnesia crown glass in conjunction with Th. Daguet, of Solothurn, and, according to H. Schroeder, these attempts had taken place before the year 1870.

A. Safarik had worked with the aim of producing glasses with proportional increase of the dispersion, and especially after the method pointed out by the 1851 jury, in order to discover new glasses which could be used as crown glasses in combination with the old crowns, the latter to take the place of the flint components. But these attempts brought no results, owing to the insurmountable difficulties attached to the meltings of silicate in the laboratory.

An extensive change, however, took place when Otto Schott, a clever technical chemist, intimately acquainted, through serious study and family tradition, with the art of ordinary glass-making, and attracted by the report of E. Abbe on the necessity for new glasses, entered into connexion with the latter. The joint work of these two men began in 1881, in accordance with the plan agreed upon between them, to study minutely all the chemical elements which can be combined in any form as an amorphous flux, with regard to their influence, both on refractive index and dispersion. O. Schott undertook the experiments on a very small scale at Witten, in Westphalia, where he resided at the time, whilst the optical examination of the results by means of spectrometric measurements was made by E. Abbe, assisted by P. Riedel. In the course of the first year certain facts were elicited on the specific effect of different substances, and it was decided to continue the work on the chemico-optical principles already arrived at, and to systematically combine glass fluxes, the properties of which should satisfy the optical requirements as far as possible, and yet possess their usual physical characters, such as hardness, constancy of composition, and freedom from colour. To this intent O. Schott, in the spring of 1882, removed to Jena, where experimental meltings were made on the larger scale required in quantities of about 10 kilos (22½ pounds).

In these experiments two independent points were kept in view. The first concerned the problem prosecuted by J. Fraunhofer and his successors, of the proportional increase of the dispersion through all the regions of the spectrum, in order to gain a more perfect degree of achromatism, and thus lessen or destroy the secondary spectrum.

The second problem, of no less importance, was that of attaining greater variation in the two chief constants of optical glass, i.e., the refractive index and the medium dispersion.

The old silicate glasses could, in consequence of the uniformity of their chemical composition, as far as their optical qualities were concerned, all be represented by a single series. They exhibited, with some few and practically unimportant exceptions, a steady increase of the medium dispersion in the same proportion as the increase of the medium refractive index. The systematic use of a larger number of chemical elements made it possible to put at the optician's disposal glasses of the same refractive index but different in the value of the medium dispersion, or other glasses in which the medium dispersion was constant, whereas the refractive indices varied. The solution of this problem being successfully accomplished, the optician was in a position to satisfy L. Seidel's condition, and to use, for the purposes of photo-optics, crown glasses with a high refractive index.

The second stage of the work, which had begun in the spring of 1882, was the founding and setting up of a laboratory, in the year 1886, by O. Schott, E. Abbe, and C. and R. Zeiss, known as the Glass Manufactory for Optical Purposes of Schott & Gen., Jena, Germany. The building of these glass works was completed in 1884, and a liberal subvention on the part of the Prussian Government contributed in no small degree to the carrying out on a large scale of the first very expensive experiments for the fabrication of glass in large masses.

In quite recent times the example given in Jena has been effectively followed in Paris, where Ed. Mantois, the successor of Ed. Feil, apparently in the year 1893-4, took up the fabrication of the new glasses. Judging from reports by Ch. Fabre and E. Wallon, it appears as if attempts with new glasses had already been made towards the year 1880, but further particulars on the results obtained at that time have not been given in those references.

DR. M. VON ROHR.

### PHOTOGRAPHY AT THE PARIS EXPOSITION, 1900.

THE Secretary of the Department of Science and Art informs us that a representative collection of British photography is in process of organization for the Paris Exhibition in 1900.

The committee of the Royal British Commission who have this work in hand are being assisted in making a suitable selection by General Waterhouse in respect of Technical and Scientific Photography, and by Mr. R. Craigie in respect of Pictorial Photography.

### PHOTOGRAPHIC CANT.

(Paper read before the North Middlesex Photographic Society.)

I do not think I know any ordeal which would be more unnerving, more trying to a naturally modest man, than to appear before one's fellow-members and to attempt to address them upon some photographic subject. It is one thing to have ideas; it is quite another to be able to put them into words. Very often, indeed, the notion which appears quite cogent in its nebulous thought form ceases even to appeal forcefully when put to the test of more or less lucid exposition. I felt about this paper as many of us have felt when we have undertaken to exhibit at some important picture show. I had neither "a title" nor "a picture;" which to get first puzzled me. I saw this difference between a paper and a picture, viz., that in one case there necessarily was a connexion between the title and the thing. I could not talk about development and call it "A Chat on Mounting," as if, so to speak, it were a photograph of a "Path through the Wood" which had become "Sand dunes by Moonlight" owing to the accidental misuse of one's "Watkins." I could appreciate the probability of your seeing through so thin a disguise and criticising me adversely. I felt that even a limitation of this kind might adversely affect my efforts—that, indeed, I was between Scylla and Charybdis—for if I chose a title, a good title, I might not be able to write up to it; and, if I wrote a paper, I might find it difficult to find a suitable and descriptive title. I have little doubt but that I should have found it a severe stumbling-block if my difficulties had not been lightened for me by a lucky accident.

I saw in my programme that Mr. Mummery would read a paper here on "Doubtful Tendencies." I had never contemplated the possibility of there being two Mr. Mummerys, that he might be a kind of double star, nor could I think what trouble of mind or body he might have been passing through. I wondered whether he might have got religion, or disapproved the judging at Pall Mall, or whether he wanted to start a presidential crusade against the "adjourned meetings." Any way, I could see that he had got a good title for his paper, and in my then mood I wondered if he would write up to it. I could not, however, think about my paper that week. Poor fellow! I wondered what his tendencies had been, and how he had succeeded in overcoming them. I was sure he had "knocked" them, because, you know, a man never comes and tells us how to do a thing, or how not to do it, unless he has been through the mill himself and solved the point. Such a thing would be anomalous, and he would undoubtedly have to pay the penalty of never being permitted again to sacrifice the time and feelings of his fellow-members whilst he practised his oratory upon them. I had to get through that week as best I could, waiting to hear what those tendencies were; but I became convinced that a good title was a most desirable thing, and especially one which left one's audience in some doubt as to what you were intending to talk about. Seeing, then, the imperative importance of securing a good title, I decided to take one which left me with the freest hand to wander if necessary over the entire range of our art.

Such a title, I venture to hope, is that one which I have adopted for my paper to-night. But I have, indeed, been fortunate in being preceded by Mr. Mummery, because, not only has he convinced me of the importance of selecting a good title, but he has also taught me that it is easier to treat a subject from the ridiculous point of view (I mean from the standpoint of one casting ridicule, which is, of course, quite a different thing).

I feel that I might have talked to you to-night, and that I should have been properly within the scope of the title of my paper, and that is a complete justification of selecting a title which allows you the widest scope upon many technical subjects which might not have been interesting to you to listen to, but which would certainly have been interesting to me to discuss, because nothing helps one to clear one's ideas so much as the having to make them clear to other people. But I am obsessed with the desire to urge you to clear your minds of cant.

Now, of all cant, the cant of the artist is about the worst. It is the most arbitrary. An artist says that a work is not true, is unconvincing, is not sincere, or is not according to one of the cant phrases of his lingo. Gentlemen, I venture to suggest to you that the interference of the artist with photographic pictures and picture-makers is itself one of the most, if not the most, doubtful tendencies which we have to contend with.

The pseudo-artist has, indeed, taught one thing, namely, to flourish about with our thumb as if to indicate how easily we could demonstrate what we mean if we only had a brush or a palette knife at hand, an artistic trick, of course, of the second-rate order, and one for which, as photographers, we could more aptly substitute some imaginary putting of the head under a focussing cloth, or of making a view-meter of one's fingers. Gentlemen, the purpose of this paper will be fully accomplished if I can but start the idea that the intrusion of the cant of artist into photography is something which makes for the decadence of our method of appeal to the emotions.

I do not think it is an easy thing to decide whether photography is more injured by the cant of the exponents of the pictorial or artistic photography, or by the worse than execrable technique of some of our photographers; but it is tolerably certain that the former make it the more ridiculous. I cannot see any reason why photographers should not be free to produce their results without the trammels of a method which is not on all fours with ours, which has not the same limitations, nor has it the same excellencies and natural advantages.

For my part, I shall be content to see our method progress by the ordinary and natural means, viz., by the method of trial and error, by trying new modes of expression, by failure, and by the retention of the best. But I am bold enough to doubt whether the assistance of the artist (using this word in its accepted sense) conduces to the desired end. I do not think that it does assist, except by the painful process of teaching us what not to do a second time.

Again, let me digress a moment to refer to a useful function which the trained draughtsman may render the photographer. I refer to the criticisms upon exhibited works appearing in a periodical devoted to the pursuit of photography. I do not think that I know any more entertaining page than *Photography* "Criticism." They are delightful reading, lucidly composed, and tolerably free from the vague generalities which the average critic has taught us to expect. But I hardly remember an instance of usable constructive criticism. Defects are pointed out in inoffensive language, but the defects are the defects of our method of expression, of photography, in fact, and are inherent, and are impossible of alteration, or in most cases of improvement. They therefore serve no useful purpose, except that of providing readable and harmless "matter" for the edification of subscribers to the paper. If the critic (he has my whole-hearted admiration for the way in which he fills a page with simple observations more or less to the point) could give advice to the younger members of some society running a series of outings, he would undoubtedly raise the general standard of the average work of that society, but it would be by teaching the young ideas what not to shoot.

I venture to prophesy that so soon as he gave constructive advice it would be to produce a photographic impossibility. Gentlemen, not only do I boldly state my feeling of regret at the effects, the now apparent effects of the intrusion of the artistic cant into a hitherto guileless photographic method of expression of nature and beauty, but I notice in Mr. Mummery's paper a kind of "get-off-the-earth" feeling, which is disclosed in his complaint that photographers reproduce artists' effects without, as he says, "having found out what they mean by them." I confess that I have never troubled myself to find out what an artist, he of the brush or any other, means by his effect unless his picture told me the tale without the asking.

When I look at pictures, singly or at an exhibition, I look at the good ones—those that I think good, if you want the admission—and pass the bad and incomprehensible ones by, unless, indeed, a picture is ugly enough or incomprehensible enough to command a second look, just as one would look at a pig with five legs, or some other of Nature's slips. This cant phrase of "what the painter means" is only used as an excuse for some work which is asserted to be "tall" art. There may be art which wants explaining, but I don't think that photographers need worry about it. The art of the camera should always be clear, and on this point I seem to be in complete accord with Mr. Mummery, although, I fear, from a different view-point: mine because clearness is a characteristic photographic quality, Mr. Mummery's because painters' effects are the artist's frehold, off which the photographers must get.

It is very easy—at any rate, it is not difficult—to cast ridicule upon a young method of expression by appearing to disdain the materials used, and calling them "blacking" and sticky. Artists' slang, like the slang of the street, is but the use of meaningless catchy phrases, and it is all cant, the cant against which I am warning the members of this Society.

Photography is so essentially a method of appeal to the great mass of ordinary people—the large majority—that we shall do well to avoid anything and everything which appears to savour of the superior person, and a photographic cult is a thing to be most carefully, most assiduously avoided.

We have many media for the expression of our work. Let us use them all, without reference to the needs, or even the jealousies, of others, and certainly without any intention of being guided by the well-meant, but not well-informed, advice as to the direction in which photography should advance. It cannot be too clearly stated that there are essential limitations upon photography which render it almost impossible for artists to correctly gauge its value; indeed, it is to the fact that some of the defects of photography must nearly approximate to qualities which the artist sometimes sees as desirable that much of the worst photography may be attributed.

Then, gentlemen, I conclude with the admonition, Let us clear our minds of artistic cant. Let us keep clear of the tyranny of the idea that the experience of the artist in his world necessarily makes him an arbiter and judge of our work. Look at his erratic awards at Pall Mall; regard the essential differences in his method of treatment, his powers of modification of his subject and drawing, and his command of colour, and think whether the man who is so trained is necessarily a suitable mentor for the photographer. Study his works, listen to his words, but always with the reservation that its application to our method may be either impossible or unsuitable.

Look at the best works of the greatest artists and the finest photographers, and you will find them for the most part simple expositions of a great subject, treated with skill and technical accuracy, and free from incongruous defects. Our greatest art should be to know what can be done well, to do it as well as it can be done, and, above all, to do it simply. The artist of the brush will always be able to excel us in constructive skill, but the photographer should be able to run him closely in exactitude of drawing, in general technical accuracy, and in freedom from incongruous defects.

I believe that the advancement of photography is more likely to be attained by submitting our works to photographers of well-balanced and cultivated taste, and to the judgment of the general public (of the class interested in photography) on its own merits, than under the patronage of artists, however high their attainments or however well intentioned they may be towards photography itself.

S. HERBERT FRY.

### THE SCIENTIFIC (?) PHOTOGRAPHER.

PHOTOGRAPHY is, or rather should be, a scientific profession, but, judging from the photographic journals, its followers are far from being scientific. Undoubtedly the present-day system, whereby all the materials may be purchased ready for use, is largely responsible for this state of things, as, when photographers can buy plates, chemicals, printing-out, and enlarging papers ready-made, a large amount of chemical and scientific skill is not absolutely necessary, and, although it is undoubtedly a great advantage, and saves a good deal of wasted time and materials, when a fair knowledge of chemistry and the chemical reactions is combined with the technical skill necessary for the production of photographs, still it can be done without, and is by a large number of photographers, both amateur and professional, of the male persuasion; the lady devotees we do not expect to know much about the scientific side, but surely a man who takes up a scientific profession or recreation ought, at any rate, to have some elementary idea of what he is doing beyond merely taking the cap off the camera, and a professional who is constantly employing chemical reactions should have a slight idea of what those reactions are, or how is he to remedy the matter if anything goes wrong? He is simply working in the dark. The usual way with most of these photographers if anything goes wrong is to blame their materials and change to another make; if that does not work well with them, possibly they write to one of the photographic papers, very often to be told that it is their own fault; probably this disgusts them with this particular journal, and they discontinue patronising it, for the last thing the unscientific photographer likes to acknowledge or be told is that spoilt work is largely his own fault. These people are the bane of the manufacturers, who can only do business with them through a dealer, otherwise the manufacturers would be continually worried by constantly having stuff returned as bad, whereas the only bad part is the unskilful way in which it is handled, for the materials are thoroughly tested before leaving the manufacturer's works, and it is seldom that anything serious is the matter with them.

It is rather amusing when advising the average photographer to try a new brand of plates or papers; the reply very often is, "I get on very well with what I use, so why should I change?" or "I do not mind trying them if I can do it with the same developer or toning bath that I am using, but I shall not make up another." Although admitting that it is not a good or desirable thing for a photographer to be constantly changing his materials, surely any photographer who takes an interest in his profession should be willing and anxious to try innovations, and see how they compare with those already in use, or how can the trade progress? I dare say many of the old wet-plate photographers thought this way when the gelatine dry plate was first introduced; but, while we

must admit the excellence of the collodion method in some ways, more particularly in printing from a collodion negative, as those who have had experience with them must confess, what sort of profession would photography be now without the dry plate? How many could or would work the old process, and where would instantaneous photography be?

Many photographers seem to do little more than take the actual negative. I suppose they would not do that, only they cannot very well help it; possibly they may develop it, but the retouching of it, printing, toning, fixing, and mounting the positive is done by one of the firms who make a business of this sort of work. This kind of thing is bound to lower the standard of the profession, as so little skill is required that almost any one can become a photographer. Under these circumstances, all that is necessary, after getting the customer, is to take the negative; the rest is done outdoors, and the photographer whose name the finished portrait bears generally has not the slightest idea what quality of paper and mount is used, under what conditions the portrait is produced, or what chance it stands of permanency. If this class of photographer does his work himself, it is often done with dirty fingers, measures, and dishes, and it is really more by "good luck than management" that he is able to turn out work worth looking at.

Numbers of these photographers say they would like to use gelatino-chloride or collodio-chloride printing-out papers, but complain that they cannot get on with them, the reason being that they expect to work them under the same conditions as albumen, which cannot be done, and then they grumble because they cannot get the same results upon albumen as others do upon the emulsion papers. Apparently they are unable to understand that albumen is incapable of giving the fine results which the others give. Probably, when they work one of the emulsion, or, as they are pleased to call them, chloride papers, they ignore the makers' instructions; in fact, many do not trouble to read them at all; consequently their results are far from satisfactory. This they put down to the paper, which they say is no good, and really is no good to them, as they will not take the slightest extra trouble with it.

A glance through almost any of the photographic journals will convince any one how little many photographers know of their profession, or we should not read of professional, or would-be professional, photographers asking, "What toning bath should I use for a certain paper?" or "What developer shall I use for a certain plate or paper?" Novices we can understand asking such questions, but men whose living it is certainly ought to know something about the matter, for nearly all the plates and papers obtainable commercially give the necessary instructions for working them, and, if these scientific (?) gentlemen would only take the trouble to read those instructions, they would save themselves and the editors of the journals they patronise a large amount of trouble. But it is when one has personal business relations with this class of photographers that their ignorance of scientific matters comes out most forcibly, and the remarks of some photographers of several years' standing are very often surprising, and really make one wonder how they get on in business at all. Fortunately, this does not apply to the better-class photographers, many of whom are conscientious workers and thoroughly up in the details of their profession, men who know what to do and how to do it.

That photographers as a body are unscientific is proved by the fact that very few of the great improvements in photography have been introduced by professional photographers, a thing which can be said of few trades or professions; for, although it is not always the case, one naturally expects that a man who is constantly using an article will understand its defects, and where and how they might be improved.

C. T. SUTTON.

### LONG-FOCUS AND TELE-PHOTOGRAPHIC LENSES.

In looking through some negatives taken with a hand camera during recent years, and more particularly the earlier efforts, I could not help noticing the large percentage of views that would have been far better if taken with a long-focus lens. This more particularly applies to marine views, river scenery, and seaside work. On seeing a good picture, naturally one mentally expresses the opinion that such-and-such a part of it will make "a pretty bit;" and if the finder on the camera is not such as to give an exact counterpart of the image produced on the sensitive plate, as in ninety times out of one hundred is the case, the result will be disappointing. For instance, a pretty bay, with a harbour forming the mid-distance, and a large ship sailing majestically out to form a nice break to the amount of sea, bathing machines and people on the shore for a foreground. To the human vision nothing could well be more charming, but, when the photographic plate is exposed and developed, the result is disappointing to a degree—everything except what is quite close is liliputian, the ship that was such a prominent object is a mere toy boat, and the harbour projection is insignificant.

One remembers taking a trip down the river, and nearing Southend a large liner is aground, with several steam tugs making an effort to get the huge ship off. The eye sees it all thoroughly well, and the picture

is bold, but a snap-shot in passing gives a result such that even with a powerful magnifier the ship and tugs can only just be made out.

Again, going down the River Rance, in Brittany, from St. Malo to Dinan, the pretty scenes on either bank are most fascinating, and, notwithstanding the river is not by any means such as would be considered broad, yet the houses, special landmarks, and interesting spots on the banks or border of the river are shown in the photographs of a size that most people would consider unimportant.

In river work, at rowing or sailing matches, &c., unless one is like the venturesome Mr. West, and had a little boat of his own to "run up" so close that they take serious risks of being "run down," the results will fall short, by a large amount, of what was desired. Instances, in fact, can be multiplied to any extent, but the above will suffice to show what cannot be done with hand cameras with lenses as usually fitted.

Before me, as I write, are four examples taken with lenses of different foci from the same spot with a rapid rectilinear and tele-photo lens. The view comprises a church on one side of a street, with a chapel connected with some almshouses in the distance, which lies back from the main road running at right angles to the street. The distance of the chapel from the camera is about 100 yards. The first picture is that mentioned above, giving the chapel 12 mm. wide on the plate, and is taken by the rapid rectilinear lens of 5 inches equivalent focus; the second taken by one half of the combination and about double the focus of the whole lens produces an image on the plate of the chapel 20 mm. broad. With the tele-photo lens, with partial extension and moderate power, the chapel appears on the plate 48 mm. broad, and, with nearly full extension or greatest power, 78 millimetres broad.

These photographs, taken to test an apparatus designed for long-distance photography, such as a war correspondent may be called upon to use if he wishes to record battle scenes, or obtain mountainous or other views, show that, even in the month of October and within four miles of Charing Cross, a passable print can be obtained from a negative having an exposure of one second with the tele-photo lens, notwithstanding the day was hazy but sunshiny, while with the 5 and 10-inch focus lenses the exposure was half a second. The stops used for the 5-inch lens were  $f/8$ ; for the 10 inch,  $f/64$ ; and the equivalent of the tele-photo would be  $f/32$  and  $f/52$  (about) respectively.

Cameras with single lenses, having a focus of 20 inches and 32 inches, are very unwieldy; but, given suitable stands so that the camera will not vibrate, some excellent results can be obtained with uncorrected single lenses, such as meniscus spectacle lenses. Two examples of hilly scenery I have that were taken by a friend of mine, Mr. Fluske, at a place in Kent, and show the objects on the distant hills, over a mile away, most clearly, while the letters on the sign-post in the foreground can be distinctly read, notwithstanding they were at a position far enough off for a man to be almost out of shouting distance. The tele-photo lens gives the same valuable result with a moderate size apparatus and with very little extra extension of the camera—for instance, with the highest magnification, only three times the normal extension.

The American makers of cameras are paying special attention to long-focus combined hand and stand cameras, and one or two of our English makers are also making distinctive patterns of this order. With careful attention to detail and convenient stays to secure rigidity, it is quite possible to have a light and efficient camera for all-round instantaneous and time exposures.

G. R. BAKER.

#### THE PHOTOGRAPHIC CONVENTION—PRESENTATION TO THE MAYOR OF GLOUCESTER.

On Wednesday, Oct. 25, at the Guildhall, his Worship the Mayor of Gloucester (Alderman Braine) was the recipient of an interesting presentation as the memento of the National Photographic Convention which was recently held in Gloucester. The presentation took the form of a framed group of the members of the Convention, which was taken by Mr. Pitcher at the Spa.

Mr. H. Medland (President of the Gloucestershire Photographic Society), who was accompanied by Messrs. H. S. Crump, W. Hodges, and B. W. Dugdale (Hon. Secretary), made the presentation and read the following letter received from Mr. F. A. Bridge, Hon. Treasurer of the Photographic Convention of the United Kingdom: "My dear Mr. Mayor,—I am requested by the Council of the Photographic Convention of the United Kingdom to ask your kind acceptance of the accompanying memento of our Gloucester Meeting, a Convention which may justly be regarded as one of the most successful ever held—a result due, not only to the efforts and assistance rendered by the Gloucester citizens generally, but the great amount of personal interest evinced in it by yourself."

In acknowledging the present, the Mayor said the photograph would remind him of one of the very pleasantest functions which took place during his year of office. He thanked them exceedingly for the present, and expressed the opinion that, if ever the Convention decided to visit Gloucester again, they would be accorded a welcome quite equal to that received last summer.

Mr. R. W. Dugdale said that, as that would probably be the last occasion they would be able to do anything in connexion with the Gloucester Convention, no doubt the Mayor would be pleased to hear that the Council had expressed the greatest satisfaction with the manner in which the affair, socially and financially, had been managed. Mr. Bridge, in a letter to him, stated, with regard to his balance-sheet, he began the year with 1*l.* 8*s.* 4*d.*, and his balance in hand now was 63*l.* 6*s.* 8*d.*, so that was all right. Locally, Mr. Dugdale remarked 37*l.* was received in subscriptions, and, after paying all attendant expenses, they were enabled to hand over the sum of 17*l.* odd to the funds of the Gloucester Photographic Society.

Mr. Medland stated that it had been arranged by the local Photographic Society to give an exhibition of slides from photographs taken by the visiting members of the Convention, on Monday, November 6.—*Gloucester Journal*, October 28, 1899.

## Our Editorial Table.

### MOUNTS FOR CHRISTMAS CARDS.

George Houghton & Son, 89, High Holborn, W.C.

ONCE again Messrs. Houghton send us samples of the mounts for Christmas photographs, the supply of which they make a speciality. It would seem that, in delicacy and tastefulness of design and effect, some-

thing approaching to perfection had been reached, for we can hardly imagine card mounts of greater refinement than those before us. The blocks illustrate two of the designs. We can cordially recommend Houghton's Christmas mounts to the attention of photographers.

## News and Notes.

WE are glad to learn that Mr. F. O. Bynoe, of Messrs. R. & J. Beck, Limited, 68, Cornhill, E.C., has recovered from the seven weeks' illness from which he has recently suffered, and has returned to business.

AMONG those who left England recently for the front was Major W. C. Beavor, Royal Army Medical Corps, who took with him a Röntgen-ray outfit for the purpose of localising the bullets. He used the Röntgen rays with great success in the Tihrah campaign.

THE LONGTON EXHIBITION.—Entries for the forthcoming Exhibition of the Longton and District Photographic Society close on Monday, November 6. Communications to be addressed to the Hon. Secretary, Mr. Thomas Mottershead, 43, Stafford-street, Longton, Staff.

MR. WILLIAM HENRY BAILEY, clerk in charge of the bookstall on the Low Level Station at the Crystal Palace, died in the Norwood Cottage Hospital a fortnight ago. The deceased, an amateur photographer, mounted the roof of the station in order to take some snap-shots of the Palace. Missing his footing, he fell and broke his leg.

ENLARGEMENT COMPETITION ORGANIZED BY THE "REVUE SUISSE DE PHOTOGRAPHIE," GENEVA.—The *Revue suisse de Photographie* is organizing, for February 1900, an international competition of enlarged prints on paper, which will be open to amateurs and professionals. Further information may be obtained from the Secretary, 40, Rue du Marché, Genève.

On November 8, Mr. C. F. Townsend, F.R.P.S., will deliver a lecture before the Borough Polytechnic Photographic Society on "Elementary Chemistry for Photographers," illustrated by practical experiments and lantern slides. An open invitation is extended to all who are interested, and tickets of admission will be sent on application to the Hon. Secretary, Mr. P. C. Cornford, 103, Borough-road, S.E.

**A LONG PHOTOGRAPHIC TELESCOPE.**—Last spring a plan was proposed at the Harvard College Observatory for the construction of a telescope of unusual length for photographing the stars and planets. Anonymous donors have now furnished the means by which this experiment may be tried. The plan will therefore take definite shape, and it is expected that a telescope, having an aperture of twelve inches and a length of 100 feet or more, will be ready for trial at Cambridge in a few weeks.

**BELGIUM.**—The Lantern Night at the Royal Photographic Society at Pall Mall, on Saturday next, is to be devoted to Belgium, when some 200 slides from negatives taken during the Belgium Photographic Excursion, organized by Messrs. William F. Slater and Walter D. Welford, will be shown and described by the latter gentleman. Some twenty members of the party have contributed, and, as some good workers went the trip, the slides should be of excellent quality. The evening will also form a reunion, as several of the Provincial members of the excursion have signified their intention of being present to see the display and the Exhibition generally, and to meet again together.

**THE BOOTLE EXHIBITION.**—The following are the Judges' awards in the Open Classes.—Class VII.: Silver medal (No. 180), Mr. C. Court Cole, F.R.P.S., Oxford; bronze (No. 218), Mr. R. Eickemeyer, jun., New York. Class VIII.: Silver medal (No. 222), Mr. C. Court Cole, F.R.P.S., Oxford; bronze (No. 232), Mr. H. C. Leat, Bristol. Class IX.: Silver medal (Nos. 258-263), Mr. W. E. Inston, Liverpool; bronze (Nos. 252-257), Mr. W. Fisher Ward, Bantry. Class X.: Silver medal (No. 307), Dr. Saunders, Bootle; bronze (No. 295), Mr. W. F. Slater, London. Class XI.: Silver medal (Nos. 446-449), Mr. John Beeby, New York; bronze (Nos. 401-404), Mr. E. R. Bull, London. Class XII.: Silver medal (No. 471), Mr. R. Eickemeyer, jun., New York; bronze (No. 461), Mr. C. Skelton Tyrer, Earl's Caine. Class XIII.: Silver medal (No. 477), Mr. W. J. Brooke, Doncaster; bronze (No. 482), Mr. H. C. Leat, Bristol. Gold medal for best picture in above classes (No. 471), Mr. R. Eickemeyer, New York.

We regret to record the death, which occurred on Thursday last, of Mr. William Wiggins, of Ferndene, South Shore, Blackpool, at the age of sixty-four. Up to a few weeks ago Mr. Wiggins carried on the business of a photographer in Talbot-road, Blackpool, building premises for the purpose at the corner of Abingdon-street and Talbot-road. He went from Bolton (his native town) to Blackpool about thirty-seven years ago, and commenced as a photographer and drawing-master in Adelaide-place. He attended most of the schools in the Fylde District in the latter capacity, and also taught at Rossall College. When the premises he tenanted were taken over by the Palatine Company, Mr. Wiggins removed to Talbot-road, where his business is now carried on by his eldest son, Mr. C. Wiggins. Mr. Wiggins did not take any public part in the affairs of the town, but he occupied a position in connexion with St. John's Church, which he attended. For about two years the deceased gentleman had been suffering from a very painful internal ailment, and this was the cause of his death. He leaves a family of three sons and three daughters.

It is with the greatest regret that we record the death, which occurred on Friday morning last, of Mr. Samuel Wolstenholme, photographer, Wellington Studio, South Beach, Blackpool, at the age of sixty-one years. Mr. Wolstenholme was a very prominent figure in Blackpool, having resided there for the past thirty-two years. Born at Rhodes, near Manchester, for some years he carried on the business of a photographer, and went to Blackpool in 1867. After being in Church-street, Blackpool, for some time, he took a studio at North Shore, and occupied land on the cliffs, now occupied by the Lower Walk. As his business extended, Mr. Wolstenholme took a wooden shop on South Beach, and finally became the owner of the present establishments at Talbot-chambers (opposite the North Pier), and the Wellington Studio, where he resided with his family. The deceased gentleman at one time had photographic studios in Middleton and Morecambe. In connexion with photography it is interesting to note that Mr. Wolstenholme was the first to introduce the popular stamp photographs into Blackpool. In politics he was a Liberal, but, for some years past had taken no active part in local political affairs, and last year he refused to stand for Brunswick Ward on account of ill health. He was a prominent member of the Clifton Masonic Lodge, having been connected with the Lodge for the past twenty years.

## Patent News.

The following applications for Patents were made between October 16 and October 21, 1899:—

**COLOUR PHOTOGRAPHY.**—No. 20,813. "Improvements in Apparatus for Exhibiting Photographs in Natural Colours." Complete specification. R. KRAYN.

**SYPHON WASTE.** No. 20,977. "Syphon Waste for Photographic Dark-room Sinks." J. WILLIAMSON.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

November.	Name of Society.	Subject.
4.....	Oroydon Camera Club .....	Forty-eighth Public Lantern Show.
6.....	Bradford Photo. Society .....	The Woodlands. Percy Lund.
6.....	Camera Club .....	Concert.
6.....	Cripplegate Photo. Society .....	Photographic Cant. S. H. Fry.
6.....	Kingston-on-Thames .....	Annual General Meeting.
6.....	Royal Photographic Society ..	Some Beauty Spots of English Scenery. J. A. Hodges.
6.....	South London .....	Photographic Chemistry. J. Arthur Formoy, F.R.A.S.
7.....	Birmingham Photo. Society ..	Demonstration with the "Dusting on" Process. Walter Griffiths.
7.....	Bristol and West of England ..	Elementary Technical Instruction Meeting: The Camera.
7.....	Gospel Oak .....	Negative-making. Rev. F. C. Lambert.
7.....	Hackney .....	Portraiture. Harold Baker.
8.....	Borough Polytechnic .....	Elementary Chemistry for Photographers. C. F. Townsend, F.R.P.S.
8.....	Camera Club .....	Lantern Night.
8.....	G.E.R. Mechanics Institution...	Lenses and Photo Optics. H. W. Bennett, F.R.P.S.
8.....	Photographic Club .....	Members' Open Night.
8.....	Royal Photographic Society ..	Palestine. P. B. Salmon.
8.....	West Surrey .....	Jumble Sale.
9.....	Camera Club .....	Liquid Air. Dr. W. Thompson, M.A., assisted by T. C. Hepworth, F.O.S.
9.....	Liverpool Amateur .....	Lantern in Use.
9.....	London and Provincial .....	Lantern Night.
10.....	Bristol and West of England ..	Demonstration: Sandell Multiple Plate and Film. Sandell Plate and Film Company.
10.....	West London .....	Demonstration: Gravura Paper. A. C. Baldwin.
11.....	Royal Photographic Society ..	Lucerne and its Environs. John H. Gear.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 26,—Mr. T. E. Freshwater in the chair.

Mr. J. E. HODD sought an explanation of some strange appearances on a celluloid half-plate film. What looked like a partially sensitive spot, the size of half-a-crown, appeared in the centre, but Mr. Hodd was assured that no opaque body had been placed over this spot, and the rest allowed to fog. Other spots of a like character were visible. Nor was it like uneven development. The other films of the same batch behaved satisfactorily in every respect. Whatever the cause, a remark that the affected portions showed the negative at its best must certainly be upheld. It was also thought to be not unlike some failures shown some time ago, in which it was pretty certain that the defect was the result of emanation from the camera, as, where a brass plate appeared at the bottom of the camera, in the corresponding portion of the plate was its outline, the brass preventing the fumes given off from reaching the film. Another suggestion was that water, or some fluid, had reached the film before development.

### TRAILL TAYLOR MEMORIAL.

Mr. PHILIP EVERITT (Hon. Secretary of the Traill Taylor Memorial Committee) announced that the second lecture would be delivered on Tuesday, November 14, at 66, Russell-square, by permission of the Royal Photographic Society. Mr. A. Haddon will occupy the chair, and Major-General J. Waterhouse, I.S.C., will read a paper entitled "Teachings of the Daguerreotype." Mr. Everitt wished it to be known that no tickets will be issued, and that all are invited to attend.

### COLOUR PHOTOGRAPHY.

Mr. GOWENLOCK was present to describe the new "Kromaz" system of colour photography. This system is based upon the fact that all colours are equivalent to, or can be matched by mixtures of, the three primary colours—red, blue-violet, and green. In other words, it is based upon what is known as the trichromatic theory of colour vision, and involves Clerk-Maxwell's colour sensation curves. What is new in this system is that there are two pairs of stereoscopic images, instead of three, an end arrived at in this way: The right eye is made to see one colour, the left the second colour, and both eyes the third colour. There are thus four colour records. Two are due to the green, and form a stereoscopic pair, and two are due respectively to red and blue-violet, forming in themselves a second stereoscopic pair. The four records are secured upon one half-plate by two successive exposures. A Cadett Spectrum plate is used. The red and blue records are taken together simultaneously by the first exposure. The two green records are secured by the second exposure. In the first exposure it is necessary to equalise the exposures for the red and blue by slowing the action of the latter to the time required by the red. This is done by the insertion of an orthochromatic screen in front of the blue-recording portion of the plate, thus following Dr. Joly's process. The ratio of exposure with the Spectrum plate was given as—

Without any screen .....	1.
Green images .....	10.
Red image .....	30.

The blue image, as previously pointed out, is adjusted for the same exposure as the red in this system. A single-lens camera is used. The stereoscopic effect is secured by the use of Brown's stereoscopic mirrors, which are supported immediately in front of the lens and transmit two images to the plate. To the back of the camera is attached a repeating back, taking a half-plate slide in which are placed the red, blue, and green screens. Any ordinary front focussing camera may be used, and the adaptation required is by no means extensive. A plate sensitive to all the colours of the spectrum is

necessary. Such a plate is found in the Lumière Panchromatic and in Calett's Lightning Spectrum plate. The colour screens sent out with the apparatus are adjusted to these plates. Care, of course, is required in handling such plates. They should be put in the back in darkness, or in a "safe light"—Calett's to wit. A safe light may be obtained by facing the ordinary ruby lamp with red and green tissue paper. After exposure, the plate is developed as usual. Metol is specially recommended, but ortol, pyro soda, &c., may do as well. A positive, by contact, on a transparency or photo-mechanical plate, is then taken. There was no strict necessity for black tones in the transparency, but the density should be looked to. Mr. Gowenlock passed round a plate containing the four negatives, and a positive plate therefrom. The exposure for the negative was twenty seconds; stop,  $f/8.5$ , the speed of the plate being 256 H. & D. The Lightning Spectrum plate was used, the place being a well-lighted studio. Long exposures were found to result in flatter pictures than short exposures, by which brightness was best secured. For viewing the positives in the chromo-stereoscope, daylight is to be preferred. Failing this, the electric arc is the best artificial illuminant. Incandescent gaslight was the best that could be arranged for at the meeting. This is somewhat deficient in blue rays, consequently the whites are not purely shown. In conclusion, Mr. Gowenlock explained the apparatus, the operations, &c., and passed round negatives and positives for examination.

A number of questions were put to the speaker. The spectroscope, it was found, revealed certain discrepancies between the screens and the statement that they complied with Clerk-Maxwell's colour curves. They did not appear to cut off strictly according to the theory named.

Mr. GOWENLOCK replied that practically the screens did all that was required. It was their wish to place the process before photographers cheaply. Therefore to make every set of screens theoretically perfect (practically they were) was impossible. It would mean that one in ten alone would be passed. He wished to state that the screens brought up were chosen at random. Of course, it must also be remembered that the screens were adjusted to the Spectrum plate. The peculiarities of this might alone account for the screens in themselves appearing to diverge from Clerk-Maxwell's actual curves. There was a little, but not much, variation of colour sensitiveness between different batches of emulsion. With regard to the fact that two images of the green sensation were taken, the excess of that colour was reduced or subdued in the viewing instrument. The process could be worked with a quarter-plate camera, but stereoscopic effects would have to be abandoned. Four exposures would in this case be necessary, on two plates.

#### PHOTOGRAPHIC CLUB.

OCTOBER 25.—Mr. L. Medland in the chair.

The CHAIRMAN showed a negative and a print of a group in which the hat of one of the figures in front, was transparent to such an extent that a figure standing behind could be plainly seen through it. The perpetrator of the photo had assured him that this was no practical joke, and that during the exposure nothing had happened which would account for the phenomenon.

Mr. F. A. BRIDGE said that, although he did not doubt the *bona fides* of this statement, he was perfectly satisfied that it was substantially incorrect. The hat was evidently only on during part of the exposure, and—barring ghosts—this was the only explanation of the incident.

Mr. A. MACKIE was of the same opinion, and he pointed out that this was corroborated by the negative, which on closer examination revealed the fact that the hat in question had received a shorter exposure than the rest of the picture.

Mr. J. NESBIT after having examined the negative, finally disposed of the question by stating that the transparent hat was the only ghostly thing about the whole business.

The CHAIRMAN then introduced Mr. C. Dalgarno, who after having tramped through Europe during the last twenty years, lately took to cycling, and, having completed his outfit by buying a camera, rode to Trieste and back, taking snap-shots on the way. The tour as described by Mr. Dalgarno by the help of a number of slides proved an exceedingly interesting one. Through sleepy Moselle valleys he took his audience up to the more stately Rhine, and thence to Nuremberg, that Bavarian town so brimful of reminiscences of a glorious past. From here *via* Regensburg to Passau, where the Danube is first capable of carrying freight steamers and then over the Alps, past many a snow-clad mountain, down to where the blue waters of the Adriatic reflect an Italian scenery. Then back through Switzerland and over the Black Mountains, through Alsace Lorraine and the Ardennes to England, Home and Beauty.

A hearty vote of thanks was passed to Mr. Dalgarno for his very interesting and instructive lecture.

**Liverpool Amateur Photographic Association.**—A very good audience assembled on Tuesday night, October 19, at the rooms of the above Association, to hear Mr. G. E. THOMPSON lecture on

#### SOME DODGES OF LANTERN-SLIDE FINISHING.

Mr. Thompson, who is an expert in the art of slide-finishing, showed his audience the method of putting in clouds in lantern slides by means of stump and pencil, the drawing of diagrammatic slides, and the colouring of photographic slides. A large number of slides, made and finished by Mr. Thompson, were passed through the lantern, and were much admired by the audience. At the close of the lecture Mr. Thompson gave a practical demonstration of the dodges he had advocated in the lecture, the audience taking a great deal of interest in the various operations.

OCTOBER 28.—The attraction of the evening was a lecture given by the eminent local artist, Mr. R. TALBOT KELLY, R.B.A., whose beautiful portrayals of Eastern life and scenery are familiar to all visitors to the local galleries. A crowded audience had assembled to welcome Mr. Kelly, who had selected as his subject

#### SARACENIC ARCHITECTURE AND DECORATION.

The lecturer, by means of a number of lantern slides of his own manufacture,

pointed out the salient features of Saracenic art as seen in the mosques of Egypt, laying special stress on the beauty of the domes, the inlaid work of the interior, and the pointed arches. In dealing with the beautiful inlaid work of the interior Mr. Kelly had taken infinite pains in order to find the fundamental principle underlying the complex geometrical design, and by the aid of a series of slides made of sketches showed that a simple cross was the foundation. Mr. Kelly also showed a number of slides illustrating beautiful metal work, both ancient and modern, and Saracenic art in its relation to domestic architecture, as shown by the overhanging balconies so prominent a feature in Egyptian street scenes. In conclusion the lecturer drew a striking comparison between the Saracenic art and the Moorish as seen at the Alhambra.

#### FORTHCOMING EXHIBITIONS.

1899.  
November 3, 4 ..... Photographic Salon. Hon. Secretary, R. W. Craigie, The Camera Club, Charing Cross-road, W.C.  
" 3-11 ..... Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.  
" 3-19 ..... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.  
" 15-17 ..... Hackney Photographic Society. W. Selfe, 70, Paragon-road, Hackney, N.E.  
" 20-25 ..... Longton and District Photographic Society. Thomas Mottershead, 43, Stafford-street, Longton, Staffordshire.  
" 27-Dec. 18. American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.  
December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.  
" 11-Jan. 1900 Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.  
" 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.  
1900.  
January 29-31 ..... Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.  
April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE ECLIPSE PHOTOGRAPH AT THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

To the EDITORS.

GENTLEMEN,—Lieut.-General Tennant's two letters *re* the eclipse photograph at the Royal Photographic Society's Exhibition have just come under my notice, and I hope you will allow me to say a few words to save the photographic reputation of the exposé of photograph No. 357.

General Tennant's explanation in his second letter by "partial reversion" is the true one, and many of us are familiar with this phenomenon, which is by no means uncommon.

Fortunately, or unfortunately as it really was, a similar photograph of the (partially) eclipsed sun was obtained at our camp at Viziadrug, on the West Coast of India, during the last eclipse. It was intended to make, with a 5×4 folding Kodak, four exposures during totality of fifteen seconds each, and the instrument was put in charge of a blue-jacket, who received the necessary instructions. While the last exposure was in progress the sun appeared from behind the dark moon, and a positive from this negative appears as follows: The portion of the sun that is appearing is black; the moon, which in all the other three photographs secured is black, is in this one nearly white, but of sufficient density to

allow one to differentiate between the limb and the white (bright) corona. The photograph gives one the impression that a white disc is passing in front of a dark one.

Although I have not seen No. 357, I think there must be a considerable resemblance between these two photographs, but the cause of their peculiarity is undoubtedly a case of "reversal," due to the extreme brilliancy of the exposed portion of the sun.—I am, yours, &c.,

WILLIAM J. S. LOCKYER.

*Solar Physics Observatory, South Kensington, October 27, 1899.*

## THE COMBINED BATH AND GELATINO-CHLORIDE PAPER.

To the Editors.

GENTLEMEN,—For a long time past I have used a certain P.O.P., and found it to give me more uniform results in tone than most other papers I have tried. The tone I like is a warm purple-brown with pure whites, and these I have invariably succeeded in getting until recently with the combined bath, made according to the formula. I never could get uniform and satisfactory results with the separate toning bath of sulpho-cyanide the makers recommend, though they say that, if their formula is followed, a range of tone from sepia to purple-brown and black can always be secured by using a proportionate quantity of gold and sulpho-cyanide to a certain number of prints, the quantity of water being immaterial. Whatever the cause, I have not succeeded in getting anything like satisfaction or uniform tone by this method, and have therefore stuck to the combined bath; but the last packets of paper I have received from them have not given me the usual results with the combined bath, so that I begin to suspect there is something wrong with the paper, that it is falling off in quantity, or else they have sent me a very old or defective sample. I have always been satisfied with both their bromide and P.O.P. paper, which has invariably given me good results. But I wish to try other makers, and I shall feel greatly obliged if any reader will inform me the maker or makers whose paper he considers capable, with careful and proper manipulation, of producing the best and most reliable work.

As regards the question of permanency, I am aware that your views are in favour of separate toning, but the method I have adopted for some years in using the combined bath has given me prints which certainly keep as well, if not better, than those I have toned and fixed in separate baths. The size of the plates I work is 10×8, and in toning with the combined bath I simply float the prints on the solution just in the same way as you sensitise albumenised paper. The action of the bath is thus confined to the sensitive surface of the paper, and the solution does not penetrate the pores of the paper at the back, so that the amount of washing to get rid of the hypo is considerably reduced, the purity of the whites, I believe, is improved, and a greater chance of permanency assured. I generally float the prints from fifteen to twenty minutes, and if the desired tone is acquired in less time, I remove the print and float it on a plain solution of hypo for the remainder of the time, so as to ensure perfect fixation. I do not for a moment suppose that professionals, who tone and fix their prints in large batches, would take up this plan, but for amateurs, who work from 10×8 to 12×10 and larger plates, and desire the best results, I think it worth consideration.—I am, yours, &c.,

THOS. MITCHELL.

## CHEAP ENLARGEMENTS.

To the Editors.

GENTLEMEN,—I am sending you herewith a cutting from the *Sun* of to-day's date, and a copy of a letter I have addressed to the proprietors of that journal. May I ask you to give them both further publicity in your columns, in order that the profession generally may know of their latest competition and do what they can to meet it. I might suggest that each photographer should display the *Sun's* offer together with a specimen of what he himself can supply at the same price, when I venture to predict that the general average of the quality of the photographer's work would be found to be better than that supplied by the paper.—I am, yours, &c.,

DRINKWATER BUTT, F.R.P.S.

35 Keppel-street, Russell-square, W.C., October 26, 1899.

[COPY.]

To the Proprietor of the "*Sun*," Temple Avenue, E.C.

DEAR SIR,—I note that in your issue of to-day's date you are offering crayon portraits at 6s. 6d. each. You are, of course, quite within your rights in adding photographic work to your business of newspaper publishing (though photographers will not thank you for introducing further competition in an already overcrowded business), but you might at least refrain from adding the following, as you do in your statement that "these portraits would cost four or five times the amount if ordered through artists in the ordinary way," which is nothing more or less than an insinuation that such things are ordinarily much over-charged for. As a matter of fact (and as you will very quickly find out if you have courage enough to publish this letter), almost any photographer can supply work of the same size and quality as you are doing at the same price. Where a higher amount is charged, there will be found a corresponding increase in the quality of the work.

I am calling the attention of photographers to your offer in order that they may have an opportunity of expressing upon it the same kind of opinion that you would probably arrive at if you found a syndicate of photographic artists offering for a farthing an evening paper of a quality that would cost a half-penny if ordered of the *Sun* office in the ordinary way.—I am, yours faithfully,

DRINKWATER BUTT, F.R.P.S.

[The offer of the *Sun* is the not unfamiliar one of a bromide enlargement for 6s. 6d.—EDS.]

## ORTOL.

To the Editors.

GENTLEMEN,—In the *JOURNAL* for the week is a request from a correspondent ("Mew") for a formula for using ortol. Professor Bothamley wrote an excellent article upon it, which appeared in *Scraps* (November, 1898). It stands thus:

### ORTOL SOLUTION.

Ortol .....	140 grains.
Potassium metabisulphite .....	60 "
Water up to .....	20 ounces.

### SODA SOLUTION.

Soda crystals .....	2 ounces.
Sodium sulphite .....	2 "
Potassium bromide .....	20 grains.
Water up to .....	20 ounces.

For general purposes take ortol solution, 1 part; soda solution, 1 part; water, 2 parts. In cold weather use water, 1 part. I have used this with success.—I am, yours, &c.,

Stradbroke, Eye, October 28, 1899.

WM. GIRLING.

## THE TRAILL TAYLOR MEMORIAL LECTURE.

To the Editors.

GENTLEMEN,—I shall be much obliged if you will permit me to inform your readers that the Second Traill Taylor Memorial Lecture will be delivered by Major-General Waterhouse on November 14, at eight o'clock p.m., at 66, Russell-square, by kind permission of the Royal Photographic Society. The subject of the lecture is "Teachings of Daguerreotype," and Mr. A. Haddon has kindly consented to take the chair. Admission will be free, without ticket.—I am, yours, &c.,

P. EVERITT.

88, Evering-road, London, N., October 30, 1899.

## Answers to Correspondents.

- \* All matters intended for the text portion of this *JOURNAL*, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

J. Landon, 134, Queen's-road, Watford.—Photograph of Alfred Augustus Cooke.

W. Harvey, 132, Townhead, Kirkintilloch, Scotland.—Photograph of Free St. Andrew's Church, Kirkintilloch.

RECEIVED.—ANXIOUS; COPYRIGHT; PRINTER; DE LAWIS; PHOTOFAD; O. CLARK; AGREEMENT; VERAX; M. G. A.; and others. In our next.

VALUE OF NEGATIVES.—INQUIRER says: "Enclosed please find three prints for your inspection. I have had an offer to sell the negatives from which these prints were taken, and would like to know what, in your estimation, they are worth to sell outright."—In reply: The negatives are worth from 5s. to 10s. each, not more.

BUILDING ACT.—C. R. W. If the District Surveyor tells you the plans for the studio are not in conformity with the Building Act, you had better alter them. If you contest the matter, it will cause you a deal of trouble and delay, and, what is more, you will probably have to give in in the end. We may tell you that we do not think your reading of the Act is the correct one.

WHITE SPOTS ON PRINTS.—W. CARTWRIGHT says: "The white spots on this print are caused by the paper sticking to the plate through dampness. The deposit remains on the plate. Will you kindly tell me what would dissolve it from the plate?"—Possibly the deposit may be removed by soaking the negative in water and then carefully rubbing it off. If this fails, try King's solution, sold by Marion & Co. It is possible, however, that the negative is irretrievably ruined.

**PLASTER OF PARIS.**—B. WARNER says: "I have been attempting to make some plaster casts from gelatine reliefs. I can get the reliefs all right, but my trouble is that the plaster takes a long time to dry, and, when dry, crumbles all to pieces. It is not hard like the plaster casts one buys. Can you give me any enlightenment on the subject?"—If the plaster behaves in the way stated, it is bad. Get some freshly made from some of the plaster-image-makers in the neighbourhood of Leather-lane, Holborn. They have it specially for their purposes, and that will answer yours.

**CONTINUOUS PRINTING.**—H. MOREL says:—Can you inform me where to obtain a quarter, half, or whole-plate printing machine to make continuous exposures on any length strip of paper, or a machine for all sized negatives to do same work? If not now in use, have such machines ever been invented? who were the patentees, and at what date did they apply for the patent?—Urie's patent printing frame. It makes the exposures automatically on a strip of paper of any length. Marion & Co. are the agents for its sale. The patent was taken out early in the year 1885.

**INDIARUBBER SOLUTION.**—T. C. BIGGS writes: "Can you tell me how to make a thin solution of indiarubber for mounting? I have made several attempts, but failed, though I have used the best No. 1 benzole. The rubber I tried first was part of the tyre of a 'bike,' then some rubber tubing, but could get neither to dissolve."—The rubber tried was the vulcanised, which will not dissolve in benzole. The unvulcanised rubber must be used. The simplest thing to do is to purchase a tin of solution at any of the shops, and then dilute that with benzole to the consistence desired; it will save a lot of trouble.

**IRON DEVELOPER FOR WET PLATES.**—R. PHILLIPS says: "The iron developer I make according to the formula in the ALMANAC gets brown after it has been kept for a week or two. Is it of any use when in that condition?"—Yes, only it works a little slower. Some of the old workers prefer it in this condition, as they find it work cleaner and give greater vigour. For this reason they often use the common coppers of the shops, because the crystals are generally somewhat oxidised, and give the brown solution at once. When the crystals are much oxidised, a little more of the salt should be used in making the solution.

**MOUNTING BROMIDE ENLARGEMENTS.**—L. H. C. asks: "Would you kindly answer how bromide enlargements are mounted for painting in oils, and if the surface is prepared in any way; whether a coat of varnish first would be best; if they are permanent? and I should be glad of any other information on the subject."—Simply mount the prints with starch in the ordinary way. It will be, in many instances, advantageous to give the surface of the picture a thin coat of size, but with glossy papers this is not required. The permanence of bromide pictures depends very much upon the care bestowed upon them in their production.

**TONING FORMULA.**—H. N. B. asks: "ALMANAC, 1899, p. 944. 1. What is the toning formula with bromide of copper followed by ammonia? 2. What is Carey Lea's formula, referred to? 3. What is Schlippe's salt chemically? 4. Is the gold sulphocyanide process applicable to bromides and platintypes?"—1. Bleach the image with the bromide of copper and then darken with dilute ammonia. 2. Convert the image first into the iodide of silver, and then immerse in a five per cent. solution of Schlippe's salt. 3. Sulphantimoniate of sodium. 4. No; prints by neither process require toning if black tones are desired, and that is what gold toning gives.

**TONING AFTER FIXING; ADHESIVE SURFACE.**—VARNA says: "1. Is toning after fixing of P.O.P. and developing papers with gold or uranium permanent and satisfactory? 2. If so, do the same formulae as to strength, &c., hold good? 3. I employ Fol's formula, given in the ALMANAC. It is good for a time, but afterwards loses its tackiness, and no amount of warming, &c., will restore it permanently. Can you recommend any better adhesive mixture?"—1. Gold is reckoned the more permanent of the two. 2. No; the baths are quite different. 3. Kindly refer us to the volume and page of the ALMANAC in which is printed Fol's formula, and we will give an opinion upon it.

**RUBBER STAMPS.**—STAMPS says: "Would you kindly inform me how rubber stamps are made? Can I obtain any book of instructions? I am experimenting for the purpose of making relief stamps by a process of photography, and wish to make the stamps myself."—The method of making rubber stamps would take up too much space to describe in this column, and, moreover, the subject is not a photographic one—or one of interest to our readers. We know of no book on the subject. Messrs. Richford, Snow Hill, London, are makers of rubber stamps, and they will probably make what you require. If you were to make them yourself, you would require a vulcaniser and other appliances.

**MOUNTS.**—LUX says: "I should esteem it a great favour if you would kindly subject the enclosed card to an examination to see whether there is anything conducing to the fading or detriment of the photograph, for I have accidentally found, when mounting a picture and having occasion to remove the photograph immediately after, that a dark discolouration has left its impression on the photograph, this being evidently due to the mount. Your analysis of such matters having been so helpful to other correspondents, I trust that you will extend this favour to me. I should be glad to receive early information through your valuable paper."—We never undertake the analysis of mounts. You had better send some of them to an analytical chemist, and get him to make an analysis and report to you upon it. It does not follow that, because the back of the print was stained under the circumstances named, that the mounts would, of necessity, affect the stability of the photograph. The analyst would enlighten you on that point.

**WASHING PRINTS.**—WILLIAM PEAK says: "Will you kindly inform me what apparatus is used by professional photographers to wash large quantities of prints after toning and fixing? I have been given to understand that several stoneware sinks are used, each containing running water and a small number of prints. No apparatus made for the purpose seems to allow the water to act freely on each print without danger of tearing."—Many different forms of washing apparatus will be found in the catalogues of the dealers in photographic goods. Some prefer one form and others another. Many, perhaps the majority, of professionals prefer to wash the prints in running water, keeping them in motion by hand, and changing them from one vessel to another.

**VARIOUS.**—CONSTANT READER says: "1. Can you tell me if the following developer is correct strength for studio portraits. Of ten per cent. solutions, I take: pyro, 10 minims; bromide potass, 10 minims; soda (accelerator),  $\frac{1}{2}$  ounce; to each ounce of developer? 2. Where can I get the new show mounts with circular four-inch openings? 3. Kindly say if the enclosed portrait is properly lighted. Any information will greatly oblige."—In reply: 1. All depends upon the soda accelerator, the composition of which is not given. 2. Any of the houses that make a speciality of photographic mounts, such as Marion's, Houghton's, &c., supply them. 3. The portrait would have been better with less front and more side light, so as to have secured greater rotundity.

**THE HON. SECRETARY OF THE CARDIFF BOHEMIAN CAMERA CLUB** writes: "I have been requested by the Committee of above Club to inquire whether you have any prize lantern slides and prints that you loan to photographic societies. If so, we should esteem it a very great favour if you would loan us a few for December 14, upon which day we are holding our annual Exhibition. Many of the members have never had the opportunity of seeing really first-class work, so same would be doubly appreciated. The Club being young, anything of this description would prove doubly interesting, and such a kindness on your part be esteemed by every one."—In reply: Our correspondent should apply to the editors of our weekly contemporaries who send out sets of slides such as he describes.

**CONDENSERS.**—W. FINCH asks: "1. Is it practicable for me to make a condenser for enlarging lantern, for winter evenings indoors, with flat and hollow glasses filled with water? 2. If so, what size would be best for negatives whole-plate, and where could I get a suitable front glass? I could cut the plane side, and do remainder; if not advisable, perhaps you would kindly let me know the best or cheapest house where I could procure suitable glass for the object named and about price."—1. It is possible, but there is practically considerable difficulty in getting such lenses water-tight. 2. Eleven inches in diameter. A clock-maker would supply the glasses, such as are used for dials, but, unless you are content with very long-focus condensers, you will have to have the glasses specially bent to a greater curve than the commercial articles. The cost of these we cannot say.

**A MYSTERIOUS "NEGATIVE" PROCESS.**—TUFF says: "Will you kindly give me information in regards to enclosed negative on tin, which is done in a few seconds? I should like to know if I should require a special camera for working same, the method of working same, and the price of quarter-plate camera (if required); i.e., I have a quarter-plate now, and I am not sure if this will do. I should also like to know manufacturers if it is a special kind. Enclosed you will find addressed envelope for return of negative. I regret causing you this trouble, but I have tried in every way to obtain this information locally, but cannot."—The "negative" is an ordinary ferrotype such as is taken at fairs and such-like places. Any ordinary wet-plate camera will do for the work. Formulae for the process are given on p. 1056 of the ALMANAC. The ferrotype has been posted back to you.

**REDUCER FOR THE LIGHTS.**—COLONEL GUBBINS says: "Is there any reducer which will act on the high lights of a negative without attacking the half-tones and shadows? I was under the impression that persulphate of ammonia would act in that way, but by an advertisement in yesterday's BRITISH JOURNAL OF PHOTOGRAPHY it 'acts directly on the shadows.' I have a negative (of interior of St. Mark's, Venice) in which the detail in the high lights is smothered, whilst the dark shadows have none, or very little, and I want to reduce the density in the high lights only."—In reply: Messrs. Lumière state, in a paper published in this JOURNAL, July 22, 1898, that "persulphate of ammonia in aqueous solution has the property of reducing negatives by acting preferentially on the most opaque parts, preserving at the same time the half-tones and the shadows, which, as a rule, by the methods used at the present day, are the first to disappear."

**SALE OF NEGATIVES.**—NEGATIVE says: "Being a reader of your JOURNAL for some years, could you kindly advise me through your columns whether I am doing right? I, being a local photographer, attended a sale of a photographer a few weeks ago, and among other things I purchased about five thousand negatives with books of reference, &c.; they were bought in a separate lot, and of course I have advertised and added them to my business, but a local lawyer in the town has now sent me a County-court summons for 1*l.*; which he values four negatives of his people taken by the above firm which I have in my possession. I have looked through books and found he only paid about 10*s.* for sittings; I always thought the negative was the property of the photographer unless it were arranged otherwise at time of sitting, and there is no reference at time of sitting that he paid for negatives."—The negative is the property of the photographer. That has been decided over and over again, and any lawyer ought to know that if he keeps himself posted up in his profession. See appendix to a letter on the subject on p. 656 of our issue for October 13 last. Supposing there were any special agreement with regard to the negatives, the lawyer should know that his remedy was against the photographer who took them, and not against you. The thing looks very like a case of "bluff."

## EX CATHEDRA.

THE announcement which we published last week, that General Waterhouse and Mr. R. W. Craigie are assisting the Royal British Commission in organizing a representative collection of British photography for the Paris Exposition of 1900, may obviously be understood to mean that the Royal Photographic Society and the Camera Club no longer have the matter officially in hand. The original idea was that the selection should be made by a Committee jointly representative of both these institutions; but we have been informed that the very small amount of space allotted by the Exposition authorities to British photography rendered a thoroughly representative display impossible. It would therefore appear that the Camera Club and the R. P. S. have withdrawn from the work of selection. Upon what plan General Waterhouse and Mr. Craigie intend proceeding in their task of organizing a representative display of technical and pictorial photography we do not know; but, as very many of our readers have asked us to indicate what facilities will be given to would-be exhibitors to send work to the Exposition, perhaps these gentlemen may

consider it desirable to afford some enlightenment to those interested in the matter.

\* \* \*

THE winter programme of the Society of Arts, the 146th session of which commences on the 15th instant, includes several fixtures of interest to photographers. After Christmas, a paper by Professor R. W. Wood, on "The Diffraction Process of Colour Photography," will be given, and Mr. W. H. Ward is also down to read one on "The Orloff Process of Colour Printing." On March 5, 12, 19, and 26, 1900, a course of Cantor Lectures on "The Photography of Colour" will be delivered by Mr. E. Sanger Shepherd. Two lectures suitable for a juvenile audience will be delivered on Wednesday evenings, January 3 and 10, 1900, by Mr. Herbert Jackson, on "The Phenomena of Phosphorescence."

\* \* \*

A CATALOGUE of cinematograph film subjects that has been sent us by the Warwick Trading Company, Limited, of Warwick-court, High Holborn, W.C., is of very exceptional interest. In the course of over a hundred pages we find a list of some hundreds of animated photographs of popular and topical interest, ranging from the Derby to the *Dunottar Castle* leaving Southampton with General Buller on the bridge; from scenes at the London Zoo to golf at New Luffness; from pantomime subjects to panoramic views in South Africa. The length and variety of the list is a tribute to the enterprise of the Company, whose operators are at present in South Africa with the object of obtaining cinematographic films of the doings of the gallant Britons and their "brother" Boers. The Company state that they will furnish prints from their negatives "four weeks earlier than any other concern on earth."

\* \* \*

It will have been perceived, from some remarks recently published in this part of the JOURNAL, as well as the letter of a correspondent which we inserted last week, that the cheap enlargement scheme, in one of its objectionable forms, has been adopted by some of the London press. It has, of course, made its appearance before in London, and we have traced it all over the country, and now it has returned to town. The *Sun*, an

evening paper, has been offering its readers a bromide enlargement for 6s. 6d., with the assurance that the portraits "would cost four or five times the amount if ordered through artists in the ordinary way"—that is to say that, for a bromide picture which has to bear several profits at a gross cost of 6s. 6d., a professional photographer would obtain from 26s. to 17. 12s. ! We wonder how many readers of this paragraph will devoutly wish that such a golden state of things were possible !

\* \* \*

THE *Sun's* statement, to put it mildly, is inaccurate ; and we are sorry to learn that, when remonstrated with, the inaccuracy was persisted in. The bromide enlargements which this newspaper, and its many contemporaries, sells to its readers, are worth what is got for them and not a fraction more. We have no doubt that hundreds of photographers, in all parts of the country, would be only too willing to supply them at the price. If we are sorry for the intelligence of a reading public which swallows the statement that a halfpenny evening newspaper is philanthropic enough to sell for 6s. 6d. what other people charge four or five times that sum for, we still more sincerely deplore the fact that London journalism should indulge in this sort of thing. If the newspapers *must* enter into competition with photographers, let that competition be fairly conducted. It is not fair competition to say that photographers grossly overcharge their clients. We have for years objected to this feature of the cheap enlargement trade, and shall continue doing so. Meanwhile, we must congratulate our contemporary, *The Stoge*, on its very honourable conduct in regard to a similar matter. In the advertisement of an enlargement scheme which it is at present running, the statement was made that the 12s. 6d. pictures offered its readers were worth four or five guineas. The latter part of the announcement, however, appears to have been withdrawn, to the very great credit of our contemporary, who, we hope and believe, will not on that account sell one picture the less.

\* \* \*

*Nature* states that Dr. Janssen, Director of the Meudon Observatory, has issued a circular in which he announces that the success of last year's observations of the Leonid meteors from a balloon has led to arrangements being made to repeat the experiment during the forthcoming shower. Last year, a number of these meteors were observed from a balloon above Paris, though the city itself was at the time enveloped in a thick fog. It is important that numerous observations of the Leonid meteors should be made from as many places as possible ; and, as balloons render observers independent of cloudy skies, they are evidently of great advantage upon occasions such as that to which astronomers are looking forward. Two balloon ascents are to take place near St. Denis. The first ascent will be made on the night of November 14-15, with the "Aerostat," and the second, on the following night, with the "Centaur." Two seats in each balloon will be at the disposal of Dr. Janssen, who has nominated observers to occupy them.

#### MOUNTING WITHOUT THE MOUNTS BECOMING COCKLED.

In concluding the article on "Mountants and Mounting" in our issue for the 20th ult., we mentioned that the best mountant to use for the avoidance of cockling of the mounts when they are thin is a solution of gelatine, in which the

water, to a large extent, is replaced by alcohol. At the same time reference was made to the fact that success with a gelatine mountant containing a large proportion of spirit depends greatly upon conditions, as well as upon the character of the gelatine employed.

Gelatine, it may as well be explained at once, is quite insoluble in alcohol, but, if a solution of it be made in water, spirit may be added to it afterwards, the quantity depending entirely upon the character of the gelatine used and the way the alcohol is introduced. Certain conditions have to be observed, and these we shall here explain. We may first of all say that a low quality of gelatine—that is, a low quality from a gelatine-manufacturer's point of view—is, practically, more adhesive than a high-class one, and for this reason, the latter has very quick setting qualities, and before a large surface can be coated it becomes gelatinised, and in that state it is but slightly adhesive, whereas a poor gelatine sets slowly, and a large surface can be coated while it yet remains fluid and in its most adhesive state. Furthermore, with a poor gelatine a larger proportion of spirit may be added without bringing about precipitation than is possible with a high-class one.

Take for example Nelson's "opaque" or Colignet's "gold medal,"—and these are perhaps the best and strongest gelatines made—they set very well indeed, even when the solutions are applied very warm and very dilute. It will be found that, with either of them, the addition of a very little spirit to the solutions will bring about a precipitation of the gelatine. On the other hand, poorer qualities, such as are sold as soup gelatines, will admit of the introduction of a large proportion of spirit into their solutions without causing precipitation. Therefore it will be seen that what may be the worst gelatine for one purpose may be the very best for another—in this case the end in view.

In some experiments recently made we selected as a suitable gelatine for the present purpose Nelson's "No. 2 soluble," which is a very weak gelatine. It is a very pure one and free from acid or other matters injurious to photographs, for it goes without saying that this is an essential condition in any adhesive used as a mountant for silver pictures. Two ounces of this were swelled and dissolved in 4 ounces of water. Then 6 ounces of methylated spirit, free from the mineral spirit, were added very gradually and with vigorous stirring, the solution being kept hot the while. As the spirit was added, particularly towards the end, the gelatine showed a tendency to precipitate, but, by maintaining the heat and continuing the stirring, it again dissolved. This gave an excellent mountant, and with it we mounted a number of prints in a very common album, the leaves of which were thin wood-pulp boards, such as are used for the middles of cardboard, and there was no cockling whatever. Although the solution contained so much spirit, it did not separate when it became cold. It was then remelted and 2 ounces more spirit stirred in and more prints mounted with it, this time on ordinary letter paper, and even with this there was no cockling. With this solution, when cold, some of the spirit separated and floated on the top, but, with reheating and stirring, it was again taken up.

The solution now stands thus : 2 ounces of gelatine in 4 ounces of water, diluted with 8 ounces of alcohol. It should be mentioned that the spirit must be added very gradually and with constant stirring, and the solution kept at a tolerably

high temperature the while, otherwise the gelatine will be precipitated as a clot, which it will be difficult to redissolve. It would be better to warm the alcohol before it is added, as that will facilitate matters considerably. It will be seen, by comparing this mountant with the formula given in the ALMANAC, that there is a wide difference in the proportions of spirit and water, and that a different gelatine is employed. In the latter there is but one-third the spirit that there is of water, while in the former there is just twice the quantity of spirit there is of water. The advantage of this, when the causes of cockling, as explained in the previous article, are considered, will be manifest, as this mountant is almost a dry one.

The solution must be applied quickly to the dry print, as it soon sets, and for this reason, when large prints have to be dealt with, a large brush should be used; a flat hog's-hair varnish brush is a very suitable one for the purpose. Here is another point that requires attention, the print should be put, in the first instance, exactly on the place it is to occupy on the mount, as, by reason of the great adhesiveness of this mountant, it cannot easily be removed after it is once in contact with the mount. Glycerine would retard the setting of the gelatine and make the solution easier of application; but, owing to its hygroscopic properties, its use is not to be recommended for silver photographs.

This mountant, by reason of the small proportion of water it contains, renders it very suitable for prints that have been squeezed on to glass when it is desired to retain the gloss. This solution will keep good for a very long period, as the alcohol acts as an antiseptic, but it should be kept in well-corked bottles to prevent the evaporation of the spirit. It is a good plan, when a large quantity is prepared at a time, to put it into smaller bottles so as to avoid having to heat up the whole bulk every time mounting has to be done.

**Photography at Low Temperatures.**—Some time ago we gave a brief account of Professor Dewar's experiments with dry plates exposed at a low temperature, only twenty per cent. of the action shown at 60° on other plates taking place at 182° C. He has pursued the subject still further, and gave an account of his results in a lecture delivered before the Royal Institution a few months ago. Using a sixteen-candle power lamp, an ultra-violet magnesium and cadmium spark discharge, and a Crookes tube, he exposed plates, cooled by liquid air and uncooled, with the result that when the ultra-violet light was used, only about six per cent. of the action given at ordinary temperatures was brought about; when the other two lights were used, about seventeen per cent. of the light action was indicated in the developed plate. Professor Dewar said it was possible that the ultra-violet radiation is dissipated by the photographic film at low temperatures to a greater extent than at ordinary temperatures, through absorption and subsequent emission as a phosphorescent glow. He further thought it possible that the photographic action took place during the heating up after the low-temperature exposure, as the result of an internal phosphorescence. He considered that a more elaborate study of photographic and phosphorescent effects at low temperatures would add much to our knowledge of the chemical and physical actions of light.

**Photo-crystallisation.**—In the *School of Mines Quarterly* is a paper by Ferdinand G. Wieckman, Ph.D., describing some singular effects of light in inducing crystallisation. The substance employed was sucrose in solution, four parts to one of water, and partially inverted by dilute hydrochloric acid at a temperature of 80° C. A large number of solutions were made with the above solution, both in its condition as described, also with the acid accurately neutralised. The result was that, after exposure to direct

sunlight, the flasks containing the solutions were solid with crystals (after 135 days' exposure), while similar flasks kept in the dark were apparently unchanged, not one crystal being formed. A long list of results under various conditions is given, and the net result is that light has some especial action in bringing about a crystalline formation, a fact which it is evident may also help in forming an opinion as to the mode of its chemical and physical action.

#### ON THINGS IN GENERAL.

I SUPPOSE anybody who is anybody has been to the two so-called "photographic" exhibitions. Time was when I used to anticipate no small amount of pleasure from a visit to such an exhibition, or rather, I should say, to an exhibition of photographs. One liked to compare notes on lenses, on processes, on dry *versus* wet, and so on. Every now and then a new lens was put upon the market, and most of us were anxious to see results, and ascertain to the utmost the capabilities of the new instruments. But now all this has changed. An exhibition was started, in which the name of photograph was, indeed, invoked; but the views and studies therein shown were avowedly free from indebtedness to any amount of technical skill in photograph-taking, lenses were not necessary, good photographs were rejected, and the more extravagant the pictorial aim, and the more indefinite its execution, the greater the chance of the picture being hung. It was a new thing entirely. Some very good men took it up and, of course, it became a success, and its modes a fashion. Photographers generally have not stiff backs, and too many of them embraced the new style. They threw to the winds their laboriously acquired dexterity, and saw fame and glory awaiting them by embracing the novelty which, so lacking in a sense of proportion are some people, has actually been termed a school. And now we have it virtually admitted that indistinctness of outline makes a photograph all the nearer to fine art, nay, a branch of it, and the very essence of photography, truthfulness of outline and faithfulness to form, ignored and disgraced. Naturally a reaction will take place. It has, however, not yet begun, and the bastard production of photographic processes, degraded and abused, still attracts the photographic multitude, and that thing, apeing a painter's results, is most lauded when it least resembles a photograph and is most like a painting, but in its likeness how unlike! Let any one go to that other Exhibition and he will see yards of paper covered with various shades of various colours made to look as much like brushwork as the producers can bring about. But these imitators, with fatuous complacency, do not stop at this point. They copy the brush men in devising frames the very opposite of what they were wont to employ. We all know that the water-colourist paints now with such brilliancy and solidity that his pictures easily stand the immediate proximity of a gold mount, such as would ruin the effect if employed with the type of painting of the early part of the century, and so the new photographer has devised a new style of frame, and utterly abandoned a white margin. In some cases such a frame is capable of being a distinct gain to the effect of a photograph. But, alas! though it is so in only a few cases, the many have adopted it and clothed their pictures with sombre, heavy surroundings that kill the shadows and make the whole grey and flat, simply because of their following a fashion like a flock of geese, and without brains to devise or minds to originate. This is the cause of the woful depression that every one feels after half an hour at Pall Mall; the fatal legacy of the Salon appears to have crushed out all originality, and the inept blind followers of a mere fashion have rendered themselves a laughing-stock. I have no intention of bringing in names, or I could instance dozens of photographs that would appeal to the eye with ever so much more force if their present sombre, mournful, ill-suited mountings were removed and replaced by others more in keeping with their scale of shades. Photographers, be men, and think, and cast off this vain phantasy of imitation painting and absurd framing!

I feel very strongly on this question, and had better leave it ere I commit myself. I will turn to something refreshing and stimulating, and no anecdote, perhaps, could be more so than one which has recently again been brought forward after being, I thought, dead

and buried, though it was a pity, for I always liked that story. There was a fire at a laundry, a big blaze from fifty gallons of ignited gasoline. There was a good young man next door who kept an apothecary's shop; seizing a demijohn of ammonia, holding a gallon and a half, he hurled it in the blazing laundry. In spite of its wicker covering it smashed, liberated the ammonia, and in the twinkling of an eye the fire was put out. This is all easy reading, but listen to the sequel: "So completely was the fire extinguished that workmen were enabled to enter the room almost immediately." Now, if it had been sal ammoniac that had been thrown on to the fire, the result above described might have followed, but that workmen could enter a room almost immediately after a gallon and a half of ammonia had been thrown about is simply ridiculous. Let any one try, without a fire, and throw even a pint of ammonia on the floor, and see whether he could enter the room almost immediately; but a dozen pints! No! Let me advise photographers not to lay in a stock of demijohns of ammonia for putting out possible fires!

I want to know something about this new "photo-sculpture." Will not some kind reader of this JOURNAL give a few words of instruction? I have read the description many times over, but cannot make head or tail of it. I remember the old photo-sculpture method, run, if I recollect aright, by one of the great photographers of the day—Disderi—perhaps about a quarter of a century ago, but then he had cameras all round the room, with the sculpture in the middle; but in this new affair there appears to be but one camera. "The sitter is placed in front of a suitable background, and, by means of zonal masks and a series of arc lights, a shadow is cast upon the sitter from all sides." So I read it lately, and a similar wording has appeared in sundry other papers. What I want to know is, how can I cast a shadow from all sides?

Wellington films may be, and very likely are, destined to become a power in the land of photography, but it will do no good to them to bring forward hazardous statements about their merits. I read that they prevent halation; but there are various sorts of halation, and I see no reason for these films being any better than celluloid films in regard to, at any rate, the most important type, that from reflection at the back of the plate; and, as to celluloid films being free from it, I can say the idea is a pure fallacy. I have developed hundreds of rolls of films during the last twelve months, and have repeatedly met with examples of halation. Theoretically, of course, they should be free from the effect; but, unfortunately, they are not free.

There has been much talk lately of cloud pictures and isochromatic plates, and every one knows that, with the aid of a screen and such plates, clouds can be obtained along with the landscape, but one point in the matter is entirely lost sight of, some of the most beautiful cloud effects are obtained when the amount of sky visible is very slight, and the cloud forms are mainly indicated by light and shade on their own masses. Now, when it is remembered that the shadows in the landscape derive their illumination almost wholly from these clouds, that they are, in fact, the source of the illumination, the problem that is really presented is to take, on one plate, an object and its source of illumination; no amount of screen use or adoption of isochromatic plate will influence the relative intensities of illumination, and, though such "skies" may be included, they must of necessity be over-exposed.

I was greatly interested the other day in my perusal of Mr. Mummery's paper, "Doubtful Tendencies." It is full of sober common sense, and remarkable for its freedom from the usual art jargon about quality, tonality, values, &c. We can get plenty of value and truth in our work, and can put into it our personality and our feeling; we can exercise design and invention, we can, within a restricted area, cause it to ring with the true tones of fine art, but we get nauseated with the continuous stream of high falutin talk about the art aspects of our hobby. We want more about our processes and less about our high aims. "Damn your sentiment," said Charles Surface, and many of us would speak in a similar strain about photographic sentiment.

I have just written about Disderi, and this reminds me that, in tracing back the originator of dry mounting as applied to photographs, I can remember seeing at Disderi's place in Brompton, over thirty years ago, heaps of prints—*cartes-de-visite*—that had been

pasted on their backs, dried, and cut, ready for the dry mounting" which is commonly supposed to be quite a recent introduction.

Captain Abney's paper on "Thickness of Film," read at the Camera Club the other day, treated a topic of great importance, which he illuminated in his usual masterly fashion, bringing out considerations and points of view well calculated to make us think, and equally pregnant with food for discussion. In the remarks that followed, Mr. Cadett struck home when he alluded to the complaints of the amateur about slow fixing and drying when plates rich in silver were employed. The highest quality in dry plates cannot exist side by side with thinness of film and poorness of silver constituents. One of the most popular of dry plates owes its enormous sale, not to its innate excellence so much as to the fact that it is very regular and uniform, and fixes quickly.

The review in these pages of the Industrial Exhibition of Edinburgh, and the reference to an exhibitor who exhibited other persons' photographs in his own name without troubling to remove the actual producer's name from their surfaces, reminds me of a similar incident quite honestly brought about. Seeing that, after the fashion of dog shows, promoters of photographic exhibitions have introduced a "challenge class," so it is probable inexperienced exhibitors may lend photographs to photographic exhibitions in the same way they would send photographs of dogs to a dog show. Some little time ago a gentleman for whom I had made some dog photographs said to me, "Oh, Mr. Free Lance, I dare say you would like to know I have taken another prize, this making the third, for that photograph of my dog you made for me!" This sounded very cool till I remembered it was only at a dog show, where owners and not producers of the exhibit obtain the prizes.

FREE LANCE.

## SILVER SUB-BROMIDE.

[Translated from the Photographische Mittheilungen.]

NOTWITHSTANDING the extensive and thorough investigation of this subject, it has hitherto been impossible to demonstrate the existence of the argentous oxide combinations with certainty.

Ever since Scheele's time\* the substance produced by exposing silver chloride to the action of light has been studied, but no one has yet produced it in a pure state. Early investigators noticed that chlorine was liberated when chloride of silver was exposed to the action of light, and it was inferred, correctly, that some combination poorer in chlorine, that is to say a sub-chloride, must exist, for it was impossible to detect any pure silver in the exposed silver chloride.

The fact that the silver haloids only suffer a superficial change when exposed to light renders the chemical investigation of the resultant substance far more difficult.

It is not my purpose to consider here the products of decomposition due to the action of light upon the silver haloids, but rather the preparation of the silver sub-haloids by purely chemical means.

The method of preparation of silver sub-chloride generally given in text-books of chemistry is that first described by Wetzlar. (There are no directions as to silver sub-bromide and sub-iodide). Wetzlar's method consists in subjecting silver foil to the action of chloride of copper or iron. But I have found that this process yields principally silver chloride, and that only a small quantity of silver sub-chloride is formed at the initial stage.

I have also treated finely divided silver, prepared in several other ways, with chloride of copper and bromide of copper. In the early stage a greyish black substance is always formed, which afterwards gradually turns to white silver chloride or pale yellow silver bromide.

Investigations concerning the bromide of copper intensifier, which is extensively used in the wet-collodion process, led me to study the action of silver nitrate upon sub-bromide of copper.

By the action of bromide of copper upon nitrate of silver, bromide of silver is formed according to the following equation:—

But, if sub-bromide of copper be used instead, then sub-bromide of silver ( $\text{Ag}_3\text{Br}_2$ ),† must be formed according to the following equation:—

\* *über Licht und Feuer*, 1777.

† In conformity with the expression of  $\text{Ag}_2\text{O}$  for argentous oxide, I express silver sub-bromide by the formula  $\text{Ag}_3\text{Br}_2$ .

or, falling this, silver plus silver bromide according to the following equation:—

For the purpose of this experiment I first prepared some sub-bromide of copper by boiling copper shavings in a solution of bromide of copper, and pouring the green fluid into about ten times its quantity of boiled water mixed with acetic acid. In this way a nearly pure white powder is obtained, which is sub-bromide of copper. It must be used at once, otherwise it soon turns green, due to oxidation from exposure to air.

The sub-bromide of copper, after having been washed with water and acetic acid, was quickly dried and then treated with a ten per cent. solution of silver nitrate, care being taken to exclude the action of air as much as possible.

The white sub-bromide of copper quickly changed to a dark greyish-black substance. After washing and drying the fine granular substance was found to be quite free from copper.

An analysis was made, and the substance was found to correspond exactly with the formula of silver sub-bromide ( $\text{Ag}_2\text{Br}_2$ ).

Sub-bromide of copper prepared by other methods was also submitted to the action of a solution of nitrate of silver. The same grey-black substance corresponding to the formula of silver sub-bromide was obtained in each case.

I then treated sub-chloride of copper and sub-iodide of copper with an excess of silver nitrate solution, excluding the action of air. These sub-salts were prepared in the same way as the sub-bromide of copper, by reduction from chloride and iodide of copper solutions. Again the result was a grey-black compound, free from copper, which, upon analysis, was found to correspond with the formula of silver sub-chloride. The preparation of the chlorine compound, free from copper, was more difficult, owing to the crystalline nature of the sub-chloride of copper and its great affinity for oxygen. Moreover, the pure white sub-chloride of copper was found to be very highly sensitive to light. Placed in a well-corked bottle, and then immersed in water mixed with acetic or sulphurous acid, and exposed to sunlight, the substance soon turned black, and assumed a metallic lustre.

The properties of the three compounds—sub-bromide, sub-chloride, and sub-iodide of silver—were then investigated rather more closely. The substances were unaffected by air, and changed but little upon exposure to light. In order to ascertain the important fact, whether free silver and silver bromide were present or not, the substance was treated with mercury. Any free silver present would amalgamate with the mercury, and, as no trace was discoverable after the mercury had been allowed to act for a considerable time, the experiment was in favour of silver sub-bromide. Upon treating the three substances with nitric acid (1-3), silver was taken up, and silver bromide, chloride, and iodide remained. Upon separation of the silver haloids from the solution of silver nitrate, they were not found to differ from haloids prepared in the ordinary way.

Eder has instanced the reduction of silver sub-bromide to silver bromide and nitrate of silver by the action of nitric acid as a reaction that cannot be called in question. In accordance with it, this reaction cannot be taken as evidence against the possibility of the existence of the silver sub-haloids.

As the chloride and bromide of silver, discoloured by the action of light, are not decomposed by nitric acid, which should be the case with sub-haloids, it seems probable that very intimate combinations of chloride and sub-chloride, bromide and sub-bromide, are formed which are indifferent to nitric acid.

Hypsulphite of soda decomposes all three substances, dissolving the bromide, chloride, and iodide of silver, and leaving a residue of pure silver.

Liesegang has already referred to this property of the silver sub-haloids.

The three substances were found perfectly homogeneous under examination with the microscope, which is confirmatory of their being true chemical compounds.

Upon moistening a small particle of silver sub-bromide with strong nitric acid whilst under the microscope, the separation of pale yellow silver bromide could be distinctly observed.

Should it be proved, nevertheless, that these are not true chemical compounds, but mere admixtures, I think the closer examination of the properties of mixtures of this intimate nature will still be of some importance.

In the other case an easier and more certain method of preparing the silver sub-haloids will have been shown.

DR. OTTO VOGEL (Zurich).

## THE COMING METEOR SHOWER.

BEFORE the issue of our next number the whole civilised world will have been interested in, and, we may hope, have had an opportunity of witnessing one of the most astonishing and beautiful natural phenomena possible ever presented to human vision, and, we doubt not, many hundreds, perhaps thousands, of cameras will have attempted to record some of its phases, providing, that is, that we have a comparatively cloudless sky in the early morning of November 16 next. The odds, however, against a November night being cloudless are about three or four to one. In November every year we have on certain nights an unusual number of "falling stars," but about every thirty-three years the number visible is increased a thousand, nay, ten thousandfold—a veritable shower of stars. Those who, like ourselves, had the good fortune to witness the last display of celestial fireworks had before them a sight to be remembered to the end of their life. It was not a star here, then another, and a further one; the whole heavens were ablaze with brilliant shooting sparks, apparently diverging in all directions, but, to the expert eye, traceable in their origin to a particular quarter of the heavens as their starting point. The explanation of their presence is not difficult. A clump, so to speak, of myriads of dark bodies—disrupted portions of other heavenly bodies—of various sizes is perpetually going round in a particular orbit, the whole of the orbit being further sprinkled, as it were, with detached members of the main clump, which takes about thirty-three years to go once round. The earth, as we know, goes once round in its own orbit in one year. The two orbits almost touch at a certain point, and, when the main clump happens to pass just when the earth is at the touching point, some of these invisible flying fragments enter our atmosphere and quickly become white hot through friction with the air, and are dissipated into dust and vapour; sometimes they actually fall on the surface of the earth.

Picture an immense elliptical circus ring with horses going round once in thirty-three years, also another smaller ring separated by the slightest distance only from the larger, and with a single horse going round once a year. The single steed would know nothing of the others in a general way; but once every thirty-three years, as the group approached where the two rings touched, they would nearly come in contact, and the flying sawdust from the heels of the galloping group would plentifully bespatter the lonely steed. In this analogy we may take the sawdust to represent the stars we hope soon to see. They have the effect of radiating from a particular direction—the quarter of the heavens occupied by the constellation Leo, hence the term Leonids; but, as they are comparatively near to us, the effect of perspective gives a false impression of their direction, just as we can see the sunbeams shining in the distant landscape through a rift in the clouds, and, though really parallel apparently, radiating from a light some half dozen of miles or so away. Still Leo is the quarter to direct attention to—or, rather, the group of stars called the "sickle," or reaping hook, at one end of the constellation. At midnight this will be near the east, slightly to the north. As we do not doubt, some of our readers, who yet feel interest in the expected star shower, have not given much attention to astronomy, we may say Leo may be easily found in the following manner. Every one knows the Great Bear constellation, or Charles' Wain, and the pole star almost immediately overhead, in a line with the last two stars of the Wain; well, joining the leading horse of the Wain by an imaginary line to the pole star, and from the latter taking another line of equal length towards the east, down nearly to the horizon, just so as to make, with a third line starting from the leading horse, and running almost parallel to the horizon, an equilateral triangle, we shall find the point of the sickle at the remaining corner of the triangle; its shape is unmistakable.

To photograph the stars, the best plan would be, when they begin to "exhibit," to place on its tripod a camera, preferably one with an anastigmatic lens, at full aperture and focussed for distance. Insert a plate, and take off the cap for a few minutes, noting the exact time, and repeat this at intervals, with a fresh plate each time. The brighter fixed stars will show their position by a "trail," i.e., a short line, and any particularly bright meteor, taken by several observers at different parts of the country, could have its direction and distance accurately determined by an astronomical expert who had the plates to collate, the time of exposure being pencilled upon them.

As the presence of clouds would be a fatal bar to the visibility of the display, many earnest astronomers are intending to utilise balloons to take them above any probable cloud difficulties. Dr. Janssen, of the Meudon Observatory, announces that an experimental trip, successfully tried last year, to observe the Leonids, will be repeated on the present occasion, two ascents will take place from St. Denis on November 14-15 and 15-16, and seats will be reserved for astronomers of note, regardless of nationality.

### ORTOL, WHOLESALE DEVELOPMENT, REPEATED USE OF DEVELOPER, AND OTHER THINGS.

THE death of pyro has so often been foreshadowed, that it makes the experienced worker careful in committing himself to similar statements; and in this respect matters are worse now than ever, because the numerous attacks successfully withstood render the position of pyrogallic acid as a developer the more unassailable. In the early days we had but two reasonable developing agents for bromide dry plates, pyro and ferrous oxalate. The latter found but very few adherents in this country, the great mass of photographers turning to the former. During the following years all sorts of changes were made in the component parts, not only in relative proportions but in the accelerators also, and yet pyrogallic acid remained. It appears to me that the reason must rest between the two suppositions, either that pyro is really the very best reagent we have ever had, or that the more modern developers have not received the same amount of attention.

One can easily understand that, with only one good developer to deal with, it was thoroughly sifted and experimented upon. If any readers will turn up the back numbers of our periodicals and annuals, they will be quite surprised at the number of formulæ and suggestions. We have used ammonia, soda carbonate, potash carbonate, yellow prussiate of potash, and others. Pyro has had twenty or thirty years' experimenting, and for many years stood practically alone as a developer for dry plates. Before we could give any modern developer even elementary attention, another reagent would be put upon the market.

We must also remember the conservative feeling that exists very strongly amongst those, perhaps, whose interests are purely commercial. If they have got a good developer, why change it? Yes, why? Of course I am not prepared to say that, even with the experience and testing of a modern developer, it would be found equal to pyro. But what I wish to point out is, that probably the disinclination to change has as much to do with the position of pyro in public opinion as its supposed superiority.

As a user of and believer for many years in that reagent, far be it from me to cast even a shadow of suspicion upon its virtues, and I confess, that up to the present, not one of the developers introduced since pyro has been equal to it as an all-round first-class developing agent. Minor advantages have been gained, there can be no cavilling at this statement; skirmishes have been successful, but, when the main battle has come off, pyro has always won.

I make the assertion that, if any developer will shake pyro to its foundations, it is ortol. It is no use saying that it will take the place of the other, because there are many professionals *who will never change*; but I'll guarantee that, if ortol be given a three months' earnest trial, spread over all classes of work, the dear old pyro bottle will quickly find its way to Stevens'.

It was once rather humorously put, at a meeting where I was discussing ortol, that it was good because it was so like pyro. Well, there's something in this, as the working of ortol very much resembles the other, and the ultimate results closely approximate.

Having got so far, it is necessary that I at once make clear my position. In the old days, with hydroquinone, say, some one at once assumed the prophet's mantle, and foretold the doom of pyro; and as each new developer came out there was always some enthusiast to laud its praises up to the skies. Now this rôle I have not taken up at all. In 1892 (*vide* "The Hand Camera and How to Use it"), in contrasting hydroquinone with pyro, I said the former "had not come to stay," and of eikonogen, "I cannot deem it either good enough, or reliable enough, for every-day work." Readers must please excuse the reference to my own writings, for I want them to see that at no time have I been a jumper at new developers; nor have I in any sense jumped at ortol. I use the phrase, "jumping," as characteristic of statements made upon the spur of the moment and after very slight trial. And I can go further, and say that rodinal, metol, and others, as well as combinations of these, and other reagents, have received at my hands prolonged and painstaking investigation. And here let me add that my work with ortol, as with other developers, has been entirely of the commercial or practical nature, not the scientific or analytical tests. These latter I have always considered to be simply useless for every-day work, and oftentimes very misleading indeed. A developer to succeed must be able to be used by others than scientists with a laboratory behind them, and their opinions, from the every-day work point of view, are worthless.

As to my own credentials, my remarks are founded upon a three months' constant use of ortol, with plates, films, and papers, partly for work that had to be done, and partly for my own experiments. Let us

just look for a moment at what I have done solely with ortol during that period.

- 100 hand-camera films, Belgium Trip.
- 120 " " plates, " " up to 23 x 17.
- 20 bromide enlargements, " " "
- 400 bromide prints " " "
- 60 lantern slides " " "
- 6 Biokam films " " 25 feet long each.
- 350 lantern slides, various,
- 200 half-plate bromide prints, " chiefly half-plate.
- 150 bromide prints, 11 x 5.
- 90 transparencies, quarter, half, and whole-plate, on process plates.
- 45 cloud negatives on ordinary and isochromatic plates up to whole-plate.
- 2 gross cloud negatives, quarter, half, and whole-plate, on films.
- Several transparencies and enlarged negatives up to 12 x 10.
- About 200 hand-camera quarter-plates, various.
- " 60 half-plates, various, portraiture and landscape.
- " 12 rollable films, various sizes.
- " 50 bromide enlargements, 12 x 10 chiefly.

These are what I can remember; but, of course, there have been many little odd things. The whole of the above were developed with ortol, and, although the busy professional may laugh at the above as being work at all, yet I think it is enough to test ortol with, and, moreover, all the work up to the final washing has been my own, absolutely unaided.

In dealing with ortol I have approached the subject from three points of view—careful experimental, every-day work; and, lastly, the slapdash, or wholesale. This latter will explain the second part of the title of this article. The few experiments satisfied me, and thereupon I tackled the second and third ideas, as it was these I was aiming for. The experiments are not worth troubling the reader with, as they by themselves prove nothing of any value. It is the conclusions drawn from these and put into considerable practice that will interest. Perhaps the word "slapdash" is hardly a happy one, as I do not mean gross carelessness, but merely the power of rushing through a lot of work in a very short time and without much attention to each particular plate. I shall, however, deal with this subject more fully later on.

Now, what can be claimed for ortol? I will set them out as attractively as I can, but, mind you, truthfully as well.

1. Gives practically same results as pyro, in colour, gradation, and in the building up of the image, and in final result is, if anything, superior as regards fineness of delicate detail.
2. It allows of every modification that pyro does, and some more.
3. The use of a minute portion of hypo is a decided advantage.
4. Can be used over and over again without detriment, and keeps well even after use.
5. Cheaper than pyro.
6. Does not stain plate, paper, or fingers, even when old.
7. Is excellent alike for plates, films, lantern slides and transparencies, and bromide paper.
8. It has a very powerful continuing action.
9. Absolute absence of frilling.

Before dealing fully with these points in detail, it would be well to touch upon the actual formula. Those given by the makers are both very good, and the difference between them is merely a matter of soda and potash. There is not enough distinction between these to warrant comparison. If anything, with potash the development is just a little slower, and the result slightly softer, given equal quantities, but beyond that the matter is not worth our attention. I have generally used soda, but that has been only because I happened to have a quantity by me. I give the maker's formula and the quantities I have always made up, the idea being to utilise the whole ounce of ortol.

#### SOLUTION A.

Water (cold) .....	10 ounces.	60 ounces.
Metabisulphite of potash.....	35 grains.	210 grains.
Ortol .....	70 grains.	1 ounce.

#### SOLUTION B.

Water .....	10 ounces.	60 ounces.
Carbonate of soda (crystal) } 1½ " "	7½ " "	
or		
Carbonate of potash } ½ " "	3 " "	
Sulphite of soda (crystal) ... 1½ " "	10½ " "	
Bromide of potassium .....	5-10 grains.	30-60 grains.
Hypo solution (five per cent.)	50 minims.	6 drachms.

Equal parts give quick development and vigorous results; by adding one part of water development is slower and the result softer, given, of course, the same exposure to deal with.

The above developer works admirably in every way, and, although I experimented and decided upon another form, I did so, first, to make it simpler to mix up; and, second, to obtain greater modification. The purpose of the sulphite is merely as a colour preservative, and, as it somewhat slows the action and has a slight tendency to harden the result, I simply set about having it as a separate solution. The action of the hypo solution is rather curious, and led me to drop the idea of that being a separate bottle also. Half the quantity appears to act just as well, and a little more does no good, whilst too much merely gives fog. To save a fifth bottle I therefore put the hypo with the carbonate of soda, although, of course, I have the solution always in stock, and to work to the very best advantage the hypo should be separate; but, as in order to get greater modifying power I had to increase the number of bottles, whilst all the while trying to simplify so as to attract the busy professional to "have a try," I have left the hypo with the carbonate. Here, then, is my own formula, which, being stated in ounces, needs no calculations as to "parts."

## ORTOL.

Ortol .....	1 ounce.
Metabisulphite of potash .....	$\frac{1}{2}$ "
Water .....	60 ounces.

## SODA.

Carbonate of soda .....	8 ounces.
Hypo solution (five per cent.) .....	$\frac{1}{2}$ ounce.
Water .....	30 ounces.

## SULPHITE.

Sulphite of soda .....	10 ounces.
Water .....	40 "

(A saturated solution really.)

## BROMIDE.

Bromide of potassium ..... ten per cent. solution.

As I have before stated, the sulphite of soda is merely a colour-restrainer, and therefore the separation of it from the carbonate gives the power of altering the colour of the deposit. It also serves another purpose, viz., its omission quickens the developing action, as sulphite is a restrainer.

In actual work the only question to deal with is as to the colour of the negative. With some people, or at least with most of us in some cases, the colour does not matter. Well, then, for speed and comfort, with a resulting negative very much like pyro ammonia, use as follows:—

Normal exposure, vigorous negative: ortol, 1 part; soda,  $\frac{1}{2}$  part; sulphite,  $\frac{1}{2}$  part; bromide, 2 to 3 grains per ounce. Normal exposure, softer negative: add 1 or 2 parts of water to above. Over-exposure: ortol, 1 part; soda,  $\frac{1}{2}$  part; sulphite,  $\frac{1}{2}$  part; bromide, 5 to 10 grains per ounce. Under-exposure: ortol, 1 part; soda, 1 part; water, 3 parts.

For blacker images nearer to ferrous oxalate or hydroquinone, more sulphite must be used, and, as that is increased, bromide can be reduced. For browner deposits, omit the sulphite altogether and increase the bromide.

After the negative is fully developed, a good way to obtain the very finest detail is to flood the plate quickly with a weak solution of soda, say, 1 part of the solution to 5 or 6 parts water. It must not, however, be allowed to remain too long, and the plate must be quickly immersed in the fixing bath.

Ortol has a greater continuing action than any other developer, which means washing in water does not stop; in fact, with a fairly full-exposed plate, nothing short of the fixing bath will stop development. The advantage of this I shall show later, but it may not be desired, and therefore it is necessary to give the warning. If, after development, the negative be washed for any length of time before fixing, it will gain in density, and, if the gain is not wanted, the fact must be remembered. So great is this continuing action that a fully exposed plate may be removed from the developer as soon as the detail is fully out, and placed in plain water to finish. Indeed, I have frequently placed such negatives under the direct stream from a tap with the same result.

Another claim I have made for ortol is that it is cheaper than pyro. Yes, I know ortol is 2s. 6d. an ounce, and pyro 10d., but even then I should call ortol only about half the price. And what it will be later when the increased demand justifies a lower price, can only be surmised. It is cheaper because one solution will develop eight plates, one after the

other, very comfortably. I usually myself do more than this, but will put it mildly. For instance, with two ounces of solution I have developed twenty-two half-plate bromide prints (one only at a time), and could have gone on further, but there were no more prints. Now, neither pyro soda nor pyro ammonia will develop eight or ten consecutive plates without a marked difference in the results, to say nothing of stain.

I had some Biokam films, twenty-five feet long, to develop, and, although the frame goes into a 12×10 dish, I found it would require forty ounces of solution to properly cover the film. Now, you know I buy most of my chemicals, and forty ounces of solution rather made me scratch my head and cogitate a wee bit, so I went on developing plates and films at intervals, and as each solution was changed I put that used into a forty-ounce bottle. As soon as I got the forty ounces together, I tackled the films and got first-class negatives, as good as could be wished for. Later on, say a fortnight later, I used this old developer again as a starting solution for a big batch of transparencies and lantern plates. One got left in accidentally, and I found it as good as those finished in the new developer. I made a note of this, and about a month later purposely tested it in this way. I had a dozen whole-plate negatives to make from one transparency, and, being by contact with exposure to artificial light, it was perfectly feasible to give the whole dozen each the same exposure. I placed the frame far enough away from the gas to allow of sixty seconds, so that, if by any chance one of the exposures should vary half a second, it would not matter. Four of these films I developed in a freshly made developer, four started in the old solution and finished in fresh, and four left altogether in the old. I placed an old finished negative in the dark-room window, and, as soon as the development of a certain portion reached the density of another certain portion of the negative, it was at once plunged into the fixing bath. I purposely avoided washing, so as to eliminate any uncertainty in that direction. The result was, I could not detect one from the other in the whole twelve when dry.

Now that developing solution consisted of forty ounces of used solutions, nothing added to it, and the last-used solution put in the bottle was quite two months old. About half of it would be three months old at least; and a curious feature of used ortol is that it discolours very little with age. If we empty a used solution into a glass bottle, it will be found of a ruby tint, which in a few hours darkens somewhat. After this no further change takes place. The forty-ounce solution already referred to is no darker in tint with three months' bottled-up existence than when it had stood the first day, nor has the subsequent use of it as detailed made any alteration. Moreover, it is quite clear and bright, although of a rich ruby colour.

Readers will have already gathered from the foregoing that ortol fulfils another advantage I claim for it, viz., that it does not stain the film. If it had done so, four of those whole-plate negatives should have shown it at least, if not eight of them.

Nor does it stain the fingers. I have not taken the least trouble, but after weeks of using new and old solutions, rarely a day passing without some immersion of the fingers, and, upon some occasions, as much as three or four days in succession, from 9.0 a.m. till nearly supper-time constant immersion, there was only a faint slight yellow tinge on two nails and the first finger of the right hand, just those used most of all.

It is not quite allied to my subject, and yet it may be useful to relate my method of dealing with unknown exposures. I use four dishes, containing respectively old-used solution, freshly mixed solution, plain water with a lot of bromide in, and one nearly all carbonate of soda and very little ortol. I judge by the relative time of appearance of the image in the old solution. If exposure is right, it is finished off in the freshly mixed developer; if over-exposed, it is put into the plain water and bromide; if under, it gets a soaking in the strong carbonate solution, and possibly later returned to the new or old solutions to finish density. Very often, too, I have a large tray of plain water, into which to get rid of those developing right (continuating action again) whilst I get on with others.

Harking back for a moment to the keeping power of used ortol solutions, I ought to have said that throughout tap water was used, and even this has to pass through a large cistern on the roof before it honours my dark room. Whether distilled water would make a difference in the colour of the old solution or aid its keeping powers, I am therefore unable to say.

There was a discussion a short time ago at one of our societies as to the advisability of using a developing solution more than once. One member said it was the right thing to do provided the results were the same, but he afterwards added that they never were. This was a diplomatic utterance worthy of a Prime Minister or the editor of—well

never mind. It is open for any one to try for themselves with ortol. That is one point.

Another is as to the continuing action. Let me tell any reader desirous of testing this a very good way to do it. Take a transparency plate, expose fully under a negative, and cut the plate in half after exposure. Place the two halves in the tray and pour over the developer, and proceed with the operation until dense enough. Pour off the developer, and quickly remove one half direct to the fixing bath, putting the other under the tap for a few minutes, which in turn must also be fixed. You will soon prove that point.

The advantage claimed last for ortol, but by no means the least, is a complete absence of frilling. In the whole of the work enumerated earlier on there was not the slightest trace of a frill. But, in addition, I had the opportunity of putting this matter to a very severe test. It was upon one of those very hot days about the end of July or beginning of August, the day described in the newspapers as the hottest of the year, or the hottest for ten years, or something of that sort. Any way, it was hot enough for me with all the windows and doors open, and what it was in my small dark room, with gas burning inside a good deal of the time, I do not know. But I had to give up toning a batch of P.O.P. as the surface of the prints melted almost without being touched. The cistern on the roof had been carefully watched with mistaken zeal by the blazing sun all day, and the water was warm as it emerged from the tap. Now, I thought, is the time to try for frilling with ortol. I thereupon developed a dozen quarter-plates, and, after fixing in plain hypo, put them to wash side by side, and flat upon the grid in the sink. The water from the tap fell upon one negative, and, as all the edges were touching, of course spread all over the others. Now, with a strong stream of water, there is no better method of causing frilling than by this way of washing, there being always the tendency on the part of the water to catch the edge of each plate as it passes. But upon that occasion I had none; and, if ortol produces negatives that will stand that, then, in the words of the song, "it will stand anything."

WALTER D. WELFORD.

(To be continued.)

## CURRENT PHOTOGRAPHIC TOPICS.

[Abstract of President's Address to the West London Photographic Society.]

We wish to take up the science and practice of photography. Well and good. Now, shall we be content to remain as mere dilettante amateurs, or shall we strive each to become a master in some one or other of the many branches of the art? If the former, I beg that we may at once give up all idea of photography; far better that we should sell our apparatus for what it will fetch, and tell Mr. Brown that, having the welfare of the Society at heart, we will continue to pay our subscriptions, but that we are no longer to be counted as belonging to the elect. But, if the latter, then I say let us work away, and not be content until we know at least as much as any one else of that branch of photography which we have decided to take for our special study. The first thing needed is good technical knowledge. Let us therefore learn to know what is meant by correct exposure and correct development, and let us learn also to recognise these when we see them. A print, and consequently also a negative, which is but a means to obtain a print, should reproduce every gradation of the subject photographed, provided the gradations are within the range of the materials at our disposal; and, if they are not within that range, then our print should reproduce as many gradations as possible—that is to say, we should intentionally omit some of the gradations at either or both ends of the scale. We may sacrifice our high lights in order to obtain detail in the shadows, and *vice versa*, but all the gradations between the highest and lowest shown upon the print should be in their proper proportion to one another. Until we can produce such a print with almost certainty we have not a complete mastery over our apparatus.

To obtain this mastery we must also learn the possibilities of our lens, our plates, and our papers. The camera itself is merely a contrivance for holding the lens and plate. In its present form it is a very convenient contrivance, and when well made may be considered as without influence on the finished print. The quality of the lens is of the utmost importance, and it should, in my opinion, be the best that we can afford to buy. There is an infinite variety to choose from, but it is not for me to advise you which to obtain. We shall, however, doubtless find some form of rectilinear lens most useful at first, and can afterwards determine whether a portrait, landscape, or rectilinear, will best suit our requirements. My advice is, Go to a well-known English maker, who can be depended upon to sell you a lens as perfect as he advertises it to be; or, if you want to buy a second-hand one, get an expert to choose it, as only he can determine whether it be suitable and free from defect.

The question of plates comes next, and I say plates advisedly, because it is not to our advantage to commence with films, excellent as many of

these now are. Let our plates be slow in speed and rich in silver, in order that we may have the better chance of securing the correct scale of gradations, about which I spoke just now. Let us determine what maker's plates we are going to use, and keep to those plates. They are probably just as good as anybody else's; but don't let us buy a dozen of A's to-day and a dozen of Z's to-morrow, because each brand has its own little peculiarities, and we have not time to learn them all. We should determine also what developer suits our plates, and use no other. We must also learn a little of the chemistry of photography; get to understand how our plates are manufactured; what are the chemicals used in the manufacture; how these chemicals are affected by light, and by the developer after they have been exposed to light.

When we have mastered all these things, and are able to produce at will a print giving the result we desire, but not before, we may pat ourselves on the back and say, *Now* we are photographers.

Given a good negative, it is more or less easy to produce a good print from it. Care and a little judgment are required, nothing more. I would, however, strongly advise that we adopt one or other of the two really permanent processes now in vogue upon a commercial basis, namely, either platinotype or carbon. As a rule, beginners will not commence with these processes, being under the quite erroneous idea that they are costly, and, above all, difficult. I assure you that they are not difficult, I even doubt whether they are more expensive than silver or bromide, when the cost of chemicals is taken into consideration, and they certainly are more pleasing than either of the two last named, which in my opinion should be avoided as one would the plague. I don't mean to say that we should never make a print in silver or bromide, both are very useful for the purpose of obtaining proofs, but I do say that in all finished prints the image should rest upon an absolutely stable basis. Later on in the session, Mr. Brown will show you how easy it is to print in carbon, and I shall endeavour to do the same in platinotype. Personally, although I am accustomed to work the latter process, I incline to the opinion that the former is the more generally useful, owing to the greater range of tone which one has at command, as prints can thereby be made with almost equal facility in any colour one wishes. Again, with carbon or platinotype it is essential to have a good negative before one can get a good print, whereas with silver or bromide a passable print may sometimes be obtained from an inferior negative, and it is surely a distinct educational advantage to be obliged to produce a good negative for every print which one pastes in one's album to be handed round for the inspection of an admiring circle of lady friends.

And now, assuming that we have obtained a fair amount of technical skill, what particular branch of photography shall we take for our special study? There are many to choose from; shall we take up landscape work? This is the branch most usually selected by amateurs, and a very good one too, as it leads us out into the country and teaches us to study nature's ever-varying moods, besides giving us fresh air, at any rate, when our heads are not under the focussing cloth; moreover, it enables us to fill our albums with records of our holidays and journeys to countries beyond our own, where, owing to the novelty of our surroundings, buildings, costumes, manners, almost all things in fact, are pleasing in our eyes, if not to our noses. We can afterwards sit quietly by our firesides in the long winter evenings, and, with pipe in mouth and album on knee, enjoy our holidays over and over again.

Shall we take up *genre* work, and give pictorial representation to the scenes of every-day life? I can imagine nothing more fascinating, provided one has the necessary taste, time, and patience. Perhaps the greatest obstacle with the majority of us will be that it is almost indispensable to have the use of a studio, though it is wonderful how much may be done without one. Or shall we take up portraiture? We can become proficient in this with no more trouble than is required for landscape work or *genre*. Here, of course, some sort of a studio is a *sine qua non*. We must study lighting and pose, and, above all, the peculiar characteristics of our model, so as to be able to accentuate the important features, minimise the unimportant ones, and produce a likeness which is both artistic and natural.

Then, again, we may make photography an adjunct to other work; we may be writing a book, and wish to supply the illustrations. In such a case etching on copper plate or photogravure will be found most useful and suitable. We may be fond of working with the microscope, and wish, by means of photo-micrography, to represent the objects seen. We may be in a position to copy good pictures. Here an immense field is open to the earnest worker, and almost perfect representations of the various colour luminosities may be obtained by using the orthochromatic plates and mixed colour screens now on the market. I have heard a well-known Royal Academician state that "good photographs of pictures are superior to any mezzotints unless the etching is done by a man whose skill is equal to that of the artist who produced the picture. But pictures must be understood by the photographer, and intelligently copied, otherwise he might be at pains to render the detail of some unimportant object, and so lose the proper rendering of the subtle gradations in the colouring of some object forming the essential feature of the picture."

Photography may be made to play an important part in the study of almost any one of the many branches of physiography. Take, for instance, clouds. Here the various stratiforms and cumuliforms may be shown; also the forms indicative of various attitudes. What could

be more fascinating than the pictorial history of some mighty river from its source, say in the form of snow falling high up in some lofty range of mountains, thence passing gradually, first in the form of a glacier, then as a torrent, then as a broader stream, sometimes through lakes, sometimes past cities, until, at last, it is lost in the all-absorbing ocean.

Those who are fond of zoology will take delight in the representation of birds, beasts, and reptiles. The photography of flowers, too, will claim many votaries, and this is a branch which should especially appeal to ladies, who, as a rule, show more taste in their arrangement and display than does a mere man.

The subject may be enlarged upon enormously, but I fear that I must have wearied you long since with all this advice, so will only add that, if we wish to succeed, we must specialise, specialise; fix upon the branch of photography for which we have the greatest inclination and aptitude—the one will show you the other—and adhere to that branch until we have mastered it. To take a portrait to-day, a landscape to-morrow, and something else the day after, is not the way to find success.

Turning to other subjects, perhaps the most important matter which is now engaging the attention of photographers is the question of copyright. This is a question which probably does not appeal very forcibly to us as amateurs, but it should have our consideration and assistance as a society, as it is our duty to help by any means within our power to settle the question, once and for all, in a manner which would be satisfactory to the large and important body of men to whom photography is a means of livelihood. A Committee of the House of Lords is now sitting to consider the copyright laws in all their bearings, and it is to be hoped that they will be able to arrive at a decision agreeable to all concerned. As you are aware, a photograph has to be registered, after which it is copyright for the remainder of the author's life and seven years beyond. This is an uncertain period, and some have suggested that it should be altered to thirty years, irrespective of the life of the author; others wish that it should be made the same as for books, viz., forty-two years; whilst others, again, think that the same period should be given to photographs as artists are seeking to obtain for their own works, namely the author's life plus thirty years. Now, as a rule, a photograph quickly becomes of commercial value, if at all; whereas an artist's works are rarely in request for purposes of reproduction till after the author's death; and, this being so, it seems to me that, if a definite period of thirty years from the date of registration can be secured, it will be wise for photographers to accept such term as a satisfactory settlement of the question. But should it be necessary to register a photograph, or indeed any work of art, in order to obtain the protection of copyright? I think not. It is unnecessary to register in England a foreign work of art in order to obtain protection here; why, then, should it be necessary to register in England an English work of art? Surely it should be sufficient if every photograph bore on it a notice that it is copyright, together with the author's name and date of first publication.

Another matter which does not interest many of us, I fear, but which certainly should do so, is the National Photographic Record Association. This Association collects and tabulates photographs of all objects of interest throughout the United Kingdom, and particularly of such objects as have already disappeared, or are likely to be destroyed. The photographs are afterwards sent to the British Museum, there to be preserved as a lasting record of many things which would otherwise be forgotten. Those of you who have suitable photographs owe it as a duty to posterity to send such photographs to the Association. The only condition made is that prints must be in carbon or platinum, plain and unmounted, and not larger than whole-plate size.

There has been no very startling discovery or invention during the past year, nothing to revolutionise our existing methods of working, nothing to very much simplify the processes which we are accustomed to adopt; hypo is still indispensable, so that we yet have to waste much valuable time in washing our negatives for an hour or more in running water. Whosoever enables us to get rid of this troublesome necessity will deserve well of his country and the water companies.

Nevertheless much progress has been made in matters of minor importance. Following up the introduction of the Velox papers, we have had others, such as the Dekko and Gravura, which may be developed by ordinary gas or lamp light in a similar manner. This is a convenience, doubtless, to some, but is not a matter of paramount importance. The practical working of the Gravura paper will be demonstrated to you at our next meeting; and for it the makers claim that tones ranging through black and brown to red may be obtained by varying the length of exposure and the constituents of the developer. We have had new intensifiers and new reducers which are said to act well, and, doubtless, do so more or less, but whether or not they will do all that we have been informed they will has yet to be proved. A new form of carbon printing, called ozotype, has been invented, and examples shown by Mr. Manley; the tissue is not yet on the market, but it appears to be sensitised with bichromate of potassium and sulphite of manganese. The image is said to be visible during the process of development. No double transfer or reversed negative is required, and the bichromate is not present in quantities sufficient to injure the skin.

The Britannia Works Company has introduced a new platinum paper which they call Platona, and for which they deserve the best thanks

of all workers in this process. The Britannia Company will, no doubt, effect further improvements, and eventually give us a rough, as well as a smooth, surface to work on. Any how, a little healthy competition in the production of this particular form of paper cannot fail to be an advantage to the consumer, who has hitherto been practically in the hands of one firm only.

Of new developers there are, as usual, many; perhaps kaolin is the most important. I have not tried it, but am informed that it is very good, and more like pyro, which is still the photographer's mainstay for all-round work, than any other form of developer, with this advantage, that its keeping qualities are more durable, and that it does not stain the plates or fingers or injure the skin.

The introduction of papers which may be developed by gaslight has induced lantern-plate makers to do the same, and Edwards's kristal lantern plates are probably but the forerunners of many others of a similar character.

The popularity of the cinematograph has led to the introduction of the instrument in forms more or less adapted to the wants of amateurs, and in the biokam we have at our disposal a cinematographic view-taker, printer, projector, and snap-shot camera combined.

Then the new stripping film introduced by Messrs. Wellington & Ward should prove of great service to those of us who wish to make enlarged negatives, and do not care to go to the expense of using plates for the purpose.

Specimens that I have seen were all that one could desire. The film is mounted on paper in the usual way, and, after the negative has been developed, fixed, washed, and dried, the point of a knife is inserted between the film and the paper, the blade is run round all four edges, and the film stripped from the paper. It can then be laid upon a piece of glass, and printed through from either side at will, thus doing away with the necessity of making a reversed negative or using the double transfer process for carbon work. The film, when still attached to the paper support, can, of course, be pinned to an easel, or placed behind a sheet of glass, and an enlargement made as on ordinary bromide paper.

I cannot conclude this address without alluding to the ever-popular question of colour photography. We seek after it as the alchemists of old did the philosopher's stone or the elixir of life, and I am bound to say that I consider it to be nearly, if not quite, as illusory, at any rate to this generation; but who will dare to prophesy that a thing is impossible after realising the marvellous discoveries of the present century, and, if the progress made in the next is as great as has been the case in this, our children may yet live to reach the promised land, which to our eyes is still so very far off. And, if they do reach that land, will they be happier? Just think it out, and try to realise how things will be when the headquarters of the Royal Academy are transferred to Russell-square, and Burlington House has become a home for waifs and strays. Will a certain Council then be qualified to select the pictures to be shown at the greatest Art Exhibition of the year? Surely not.

No practical advance has yet been made towards the discovery of colour photography as the majority of us understand the expression—that is to say, in the production of an apparatus whereby we can take a negative direct from nature, and obtain, by printing direct from that negative on to paper or some other substance, a photograph which shall correctly reproduce all the varying colours of nature; but great improvements have been made in apparatus to enable us to see representations of things more or less in their natural colours, as in kromskop so cleverly contrived by Mr. Ives.

Quite recently a great advance has been made upon this invention of Mr. Ives's by Mr. E. Sanger Shepherd, who has devised a method whereby lantern slides, coloured solely by photographic means, may be thrown upon the screen from a single lantern and viewed by all, whereas formerly either a triple lantern was necessary, or else the picture could only be seen in a special instrument and by a single observer at a time.

Mr. Shepherd is one of our most clever workers in this branch of colour photography. I will therefore ask you to let me describe, in as few words as possible, the recent advances which he has made. You all know, of course, the principle of three-colour photography, that all the natural colours can be reproduced by the proper admixture of three different colours, a certain red, a certain green, and a certain blue-violet, and that white light, which is really the absence of colour, is obtained by a mixture of all these three colours in proper proportions.

Now, what Mr. Sanger Shepherd does is this: he takes negatives of his subject upon three different plates, one through a red filter, one through a green filter, and one through a blue-violet filter, the plates, of course, being properly orthochromatised. From these three negatives he makes positives in colourless gelatine, mounted on transparent celluloid, and each positive is afterwards stained, not in the colour of the filter through which the negative was taken, but in the colour complementary thereto, the reason for this being that we are now dealing with a positive of the negative taken through the screen, and not with the negative itself. The positives are then placed in exact register between two lantern glasses, and are ready for exhibition.

Gentlemen, I am very much indebted to Mr. Sanger Shepherd, who has been good enough to lend me some of his slides, prepared in the

manner just described, and these I will show to you so soon as the lantern is ready. They are most admirable slides, and I am sure that you will all, whether you have seen them before or not, join with me in thanking Mr. Shepherd for so kindly letting me bring them here to-night.

A. O. BEARD.

### A SILVER PHOSPHATE PRINTING PROCESS.

DR. JOHANNES MEYER, of New York, the patentee of this process, says it is based upon the discovery of the valuable properties of the silver phosphates when combined with organic acids, such as acetic, tartaric, citric, and succinic acids. The silver phosphates have so far not been employed for photographic or other purposes, and the only mention of any application made of them is to be found in Hardwich's *Manual of Photographic Chemistry*. He writes: "Other insoluble salts, such as the phosphate and citrate, render the paper more sensitive than when it has been treated with a soluble salt of silver only." The great value of the silver phosphates consists in their property of forming emulsions with suitable organic acids, which behave in all respects like the well-known emulsions of the silver haloid salts with albumen, gelatine, or collodion. Dr. Meyer proceeds: "I have discovered that the silver phosphates, aside from being soluble in ammonia, phosphoric acid, and nitric acid solutions, as was well known, form solutions with a number of organic acids, as, for instance, acetic, tartaric, citric, and succinic acid; but, under certain conditions, silver phosphates will form, in conjunction with an organic acid, a true emulsion."

I have studied the behaviour of silver phosphate towards tartaric acid in this direction most carefully, and, as the tartaric acid-silver phosphate emulsion is chiefly employed, I will now proceed to give directions how to prepare and how to use it.

To an aqueous solution of one drachm of silver nitrate a well-diluted solution of sodium phosphate is added. The resulting silver phosphate is well washed, by decantation, and brought to the volume of one fluid ounce. To this silver phosphate held in suspension we add five drachms of tartaric acid dissolved in five drachms of water, at the same time imparting to the containing vessel a quick rotary motion. In this way is obtained a white jelly-like mass of a volume of two ounces, containing a quantity of silver phosphate equivalent to the drachm of nitrate we started from. It is essential that all the chemicals, including the water, be chemically pure.

To render this emulsion more fluid, it is either slightly heated, or agitated with a glass rod, or by shaking the bottle. In this state it is used for coating the paper or other surfaces on which it is desired to print.

The proportions given above are the best for practical use. The preparation of the emulsion is, however, easier, for one not experienced in this special line of work, by mixing a fluid ounce of silver phosphate with a smaller quantity of tartaric acid; for instance, two drachms of acid in two drachms of water, when the emulsion will set more readily. When the emulsion is left in its jelly-like state, crystallisation will set in, after some time, while a portion of the silver is retained in the solution.

Citric acid seems to have the greatest affinity for silver phosphate. Twelve drachms of citric acid mixed with one fluid ounce of silver phosphate will produce a clear transparent solution which has remarkable sensitiveness and qualities.

The emulsion, or solution of silver phosphate in organic acid thus obtained is then applied in any suitable manner to the surface to be sensitised. It may be applied by means of a soft, flat camel's-hair brush to paper, after which it is permitted to dry. When this sensitised photographic paper is exposed under a negative to direct or shaded sunlight, a positive picture of great accuracy and agreeable tone is obtained. When the paper is first coated with albumen or gelatine, or any similar substance, a photographic print can be produced in less time than by the silver haloids heretofore employed, and not only sunlight, but also artificial light, can be used for producing a direct print. The photographic print thus obtained can be toned by any of the well-known toning solutions, and finally fixed by means of sodium hyposulphite. The print is then washed until no trace of the hyposulphite is left in the same. In place of paper, any other material, such as wood, celluloid, lithographic stone, silk, cotton, or other textile fabric, and other materials, can be coated with the photographic film, and pictures of great delicacy and beauty, not inferior to prints on paper, be produced thereon.

The advantages of my improved process of producing photographic films are that silver phosphates can be employed without the aid of a viscous substance like albumen or gelatine; that the silver phosphate emulsion, or solution, can be spread over almost any surface, like a paint or dye; and that only a very weak solution of sodium hyposulphite, and a short immersion of the prints, is required to remove the unchanged silver and render the prints permanent.

When the prints are left in the fixing bath for a longer time than a minute, the sulphuration of the prints will commence, which is induced by the organic acid, and which will be completed to blackness of the picture in a few minutes more. Though sulphur toning is believed to have many objectionable features, the prints made by the process described do not suffer in appearance if the sulphuration is not too long continued. The use of albumen will prevent the prints which have been toned by sulphur from becoming yellow and faded by atmospheric oxidation. These results were obtained by a number of tests, continued

through a considerable period of time. The dominant colour of the prints made by the silver phosphate emulsion or solution is a brown or auburn shade, which darkens considerably with the drying of the prints. Toning may therefore be dispensed with in many applications in the arts. When the prints are made on textile fabrics they are generally brown in tone, but this can be changed, in the case of cotton, to black, by passing a hot flat iron over the same, while prints on silk will not undergo this change. Though the predominating colour of the silver phosphate prints is brown, many of them show various other tones, and it must be assumed that certain negatives act as a media for the transferring of colour qualities and influence the production of the tone to a certain degree under conditions not yet known. When a silver bromide emulsion is added to a silver phosphate emulsion, the sensitiveness of the solution is so increased that even the light of a common petroleum lamp is sufficient to produce a direct print. The sensitiveness of the emulsion is also increased by the addition of a small quantity of citric acid. The solution of silver phosphate in citric acid, when applied to a plain piece of paper and exposed under the negative to direct sunlight, produces a print of very agreeable bluish tone, which will compare favourably with other prints in accuracy, in the high lights, and in the depths of the shadows.

Paper coated with albumen and sensitised with a silver phosphate emulsion or solution has great durability, and will not deteriorate under climatic influences. It can be used therefore at any time for printing, without impairing the quality of the print. . . . The print is removed from the printing frame directly to the fixing bath, to which sodium bicarbonate is added when the original colour of the print is to be preserved. The print remains in the fixing bath for a short time, and is then freed from any adhering traces of sodium hyposulphite by washing it in hot or cold water for about five minutes.

### GREAT TELESCOPES OF THE PRESENT DAY.

In his Presidential address to the British Astronomical Association, Mr. W. H. Maw remarked that the great telescopes of the present day are of a very different class to the giant instruments of the past. The great reflectors of Herschel, of Lassell, and of Rosse were all instruments made and used by amateur astronomers, and, although they possessed great light-grasp and did some admirable work, they were, owing largely to the nature of their mountings, utterly unfitted for the class of observations on which the large telescopes of the present day are chiefly employed. The thirty-six inch and sixty-inch reflectors of Dr. Common may, perhaps, be regarded as the latest of this older class of large telescopes, although it would probably be more just to consider Dr. Common's instruments as forming a connecting link between the giants of the past and present. In the case of such large refractors as those at Pulkowa, at Washington, at Vienna, at Mount Hamilton, at Nice, at the Yerkes Observatory, and at Greenwich, the cost of the telescope itself is but a small portion of the total outlay incurred. Not only must such an instrument be thoroughly well mounted to fit it for modern research work, but it must be protected by a well-constructed dome, and, in order that every moment of good seeing may be utilised, provision should be made for effecting all movements of both telescope and dome with the least possible amount of labour to the observer using the instrument. How perfectly this can be done is well shown by the great Yerkes refractor, which, notwithstanding its enormous size and weight, can, with its dome, be so readily handled by the electric motors with which it is provided, that it can be, and is, efficiently used by a single observer through a whole night without any assistance whatever. It is satisfactory to know that two of our own members, Messrs. Warner and Swasey, were responsible for both the design and construction of this admirably perfect mounting, while the rising floor, which forms such an important feature in the equipment of both the Yerkes and Lick Observatories, and contributes so much to the convenient use of these large telescopes, was the invention of another of our members, Sir Howard Grubb. But, by the time a refractor of this kind has been erected and equipped, the outlay upon it will have become so large that it would be utter folly to use the instrument for work other than that for which its great power renders it specially fitted. The result of this is that our modern giant telescopes are, with few exceptions, employed not in doing work which was formerly done by smaller instruments, but in doing work which formerly could not be done at all. Such, for instance, is the bulk of stellar spectroscopic work, including determinations of velocity in the line of sight, the measurement of close double stars, the spectroscopic examination of nebulae, the discovery of new planetary satellites, and similar matters. We see, therefore, that the establishment of these powerful telescopes has been accompanied by the development of new fields of research, and that the work which was formerly done, and can still be well done, by instruments of moderate size, has not been reduced. On the other hand, many professional astronomers have withdrawn from the work which they formerly did with the instruments then available, and they have thus left to amateur observers the continuance of their former labours. We thus see that there is ample work for the members forming our observing sections, and that such work, if faithfully carried out and recorded with judgment and discrimination, is calculated to be of great and permanent value.

## STEREOSCOPIC PHOTOGRAPHY FORTY YEARS AGO.

SENEX writes: "I have just been looking through a book, published in 1857, written by J. M. Jephson, entitled *A Walking Tour in Brittany*. The book appears to have been issued with an accompanying portfolio of stereoscopic pictures, referred to in the enclosed extract. A silver print from one of the negatives, mounted so as to be seen stereoscopically by placing a stereoscope over the page, appears as a frontispiece. The photographer who was engaged by the author to travel over the same ground and make the necessary illustrations is a Mr. Lovell Reeve, who writes an interesting note, printed in the work, of his outfit and manner of working, which I extract. It brings back vividly to those of us who were wrestling with the art in those far-off days the labour that was involved in making photographs. I wonder whether Mr. Lovell Reeve is yet alive, and also whether any of your readers have preserved a set of the stereoscopic pictures then produced."

Extract from Jephson's *Walking Tour in Brittany*, published 1857:—

"Our apparatus consisted of a small double-lens landscape camera by Ross, a black tent about four feet square and seven feet high, fitted with a table and sink, the whole folding up into a moderate-sized portmanteau, and two boxes of chemicals, one for use and the other for store, with a third box containing in a small compass a gross of glasses, comprised in six inner boxes of two dozen each. It was decided to confine our operations to the wet-collodion process, and to defer varnishing the plates until our return home. Great care was necessary so to economise our hours of travelling as to have the fairest weather and the best description of light at our disposal while at work with the camera."

"The first thing to be observed on entering a town or village was the position the sun would be in, with respect to the objects selected, at the time we should be prepared to photograph them, the points of view to be taken, and the most effective arrangement of the foreground. The next consideration was to select a place for our tent in the nearest proximity to two or more views together. The result was that we visited thirty towns and villages within the space of thirty days, pitching our tent about a hundred times, during which my active photographer, Mr. Taylor, could not have taken less than two hundred pictures, from which the present ninety have been selected for publication. Our evenings were fully occupied in looking over the day's harvest, clearing away the day's disorder, and preparing plates and chemicals for the next day's work."

## X RAYS ON THE BATTLEFIELD.

THERE can hardly be in the world of surgery a fitter sphere than the battlefield for the operation of X rays. The humane are, doubtless, consoling themselves with the thought that, while military science is doing its utmost in the way of human mutilation, surgical science is efficiently, and to the minimum of pain and inconvenience, effecting repairs. Experience unhappily hardly justifies this assumption. The surgeons are skilful and courageous enough; but they are often badly equipped in respect to ambulance appliances (says the *Birmingham Daily Argus*), and the most important of our late wars in the Soudan and elsewhere have been followed by grave expressions of dissatisfaction in Parliament on the treatment of the wounded. The replies of the War Office to critical queries undoubtedly showed that the ambulance arrangements were faulty. One such expression only need be quoted. After the battle of Atbara, the Under-Secretary of State for War stated that "there had been no case of a wounded man at the Atbara to whom the absence of the Röntgen apparatus had made any difference." The important circumstance to be noted is that the Röntgen apparatus was absent. The fact that important institutions like our own General Hospital have established a permanent radiographic department in connexion with the hospital tells its own story, and will enable the average reader to place the true value on the official reply above quoted. With the view of obtaining an expert expression of opinion on the subject, our representative waited upon Mr. Hall-Edwards, the surgical radiographer to the General Hospital, Birmingham, and found that the expert had himself been taking a special interest in this matter. He declared most emphatically that until Saturday last he had seen no notice of an X-ray expert having left this country for the seat of war. Since then several have departed, but the number is still very inadequate, and the War Department do not seem to realise the great value of the Röntgen discovery in the treatment of the wounded. Said the expert: "The proper and complete application of the X rays to military surgery must prove one of the greatest, if not the greatest, advance of the century. Yet it is a remarkable fact that in the Nile Expedition there was no apparatus, the excuse of the Department being alleged serious transport difficulties. When these were got over, said the War Office, the apparatus would form a part of the field equipment. The same statement was made two years before, and apparently no steps had been taken in the meantime to overcome the difficulty." Mr. Hall-Edwards, we may remind our readers, has devised a coil which he has himself repeatedly used in field practice on the occasion of Volunteer Ambulance demonstrations, and he is satisfied that the transport difficulties about which so much is made are imaginary. The apparatus worked perfectly, and the iron-bound case weighing thirty pounds was readily carried by a couple of men. Other requisites are a portable developing tent with stand, and a box of tubes,

photographic film, and chemicals. Although taken in an ambulance wagon, and jolted over several fields, the apparatus suffered in no way from the shaking, and worked to perfection. At the base hospital a somewhat larger apparatus, but otherwise in no way different, would amply meet all surgical requirements, and would be invaluable in the location of bullets.

Arrangements could also be made for the recharging of accumulators. Far too much, Mr. Hall-Edwards thinks, has been made of the difficulties in the recharging of accumulators; but, on the occasion above referred to, a small dynamo driven by a couple of men on a tandem bicycle admirably served the purpose, and other contrivances might be devised. Such renewals, however, would be seldom necessary, as a store of electricity carried in three such accumulators would, if used several times every day, last for some weeks. As a matter of fact, the difficulty in the application of the rays can easily be overcome.

The impossibility of securing absolute cleanliness in the treatment of wounds on the battle-fields renders any help obtainable in this direction of the greatest importance. A most important circumstance is that the rays can be applied painlessly, and without the necessity of removing dressings and splints.

An injured limb can be examined and a diagnosis made, the presence, shape, and position of a bullet or a portion of a shell can be ascertained, and the exact line, the amount of comminution, and displacement of a fracture be discovered without giving the patient the slightest pain or even discomfort, and all this without, in many instances, removing the dressings. The greatest dangers in military surgery arise from the undue exposure of the wounds to a bacteria-laden atmosphere, and to prolonged, dangerous, and (now) unnecessary manipulation. Prior to the discovery of the rays, the only method of discovering or locating bullets was by the use of a probe—a piece of blunt-pointed silver wire—which was pushed into the wound in all directions until the presence of a piece of metal was discovered. Every time the probe was introduced it carried with it a number of germs, and thus the wound was rendered exceedingly liable to infection. As a death-dealing instrument a dirty and unskilfully used probe has few equals, whilst, even in the hands of the experienced surgeon, its inherent propensity for travelling in the wrong direction has rendered diagnosis by its means a difficult and dangerous operation. To quote a recent example of surgical difficulties, Colonel Whitehead's report on the Tirah campaign related how near the heights of Dargai the box of surgical dressings was covered with dust, and the only water available was the village pond, extremely putrid through the large accumulation of sewage. The dressings were applied by a man whose hands were dirty, and there was no sterilised water carried in the equipment. The X rays, under those circumstances, would have been simply invaluable. By their means the bullet can be exactly localised, painlessly and antiseptically, and the certain diagnosis enables the surgeon to at once, and with confidence, decide as to whether its removal is necessary or not. A suggestion has been made that Birmingham should send out an ambulance corps, and the inclusion therein of a complete X-rays equipment would be a priceless boon to the brave fellows who have the misfortune to be injured on the field.

## CRYSTOLEUM.

At a meeting of the Leeds Camera Club on Wednesday, November 1, Mr. J. Skilbeck gave a lecture and demonstration, entitled "More about Crystoleum."

Mr. Skilbeck, in his remarks, pointed out that, as this lecture was practically a continuation of the one he gave last session, he would, for the benefit of any who might not have been present at that time, recapitulate the points then dwelt upon. Having dealt with the print, the selection of the glasses, and the process of clearing it by what was termed the "medium" method, he went very fully into an alternative process, known as the wax method. This process is to place the glass with its print, when properly squeezed on, into a bath of paraffin wax, and allow it to remain some two or three hours, or until the wax had thoroughly entered the pores of the paper. On taking it out, the chief obstacle to the wax method became manifest, by grey spots appearing on the face of the print in very large quantities. To this he had given a great amount of attention, and he explained to the members and visitors present the cause and its remedy. He advocated the wax method, when done properly, as being better than that of the medium, as giving finer and softer results, whilst for the thinning down of the paint in the after-process of colouring only poppy oil need be used; but he strongly cautioned them against using this oil if their prints had been cleared by the first-named "medium" method, as, with it, a preservative sold along with the medium must only be used. He said that, in washing out their brushes with turpentine, care must also be taken never by any possibility to allow any to come in contact with the surface of their work or in the paint used, for, if they did so, disappointment would surely result. In conclusion, the lecturer pointed out the advantages and beauty of the work. It enables any one having a taste for colour to produce most pleasing results, besides being a most interesting occupation, and, if they would carefully attend to those little details which he had enumerated, they would succeed.

## THE PRINCIPLES OF DEVELOPMENT.

On October 30 Mr. Watkins, at the Camera Club, gave a lecture upon the principles of photographic development, in which he endeavoured to combat some popular beliefs, which he proved had no foundation in fact. His remarks were illustrated by a number of slides, which consisted mostly of strips of developed plates, which were brought into contrast in order to show both the effect of time of exposure and nature of developer, and it was evident that these strips were the result of laborious and painstaking experiments. As he mentioned that the paper will shortly be published in *extenso*, we shall at present confine ourselves to a very general review of the ground which it covered.

Mr. Watkins commenced his discourse by pointing out that there was, for every plate, a minimum exposure below which there is no developable impression made upon its sensitive coating, while at the other end of the scale was a maximum beyond which no effort could induce further effect. It was a common belief that over-exposure led to thinness of result, but this was a mistake, for full development would ensure enough density to meet all needs. Another common belief was that metol had the power of bringing out the upper tones of the negative more quickly than any other developer. His experiments showed that all developers act in much the same ratio. Longer development, as a general rule, gives greater contrasts, but there are exceptions in particular plates, in which the rule is not followed. Each make of plate on the market has its limitations. A few years ago he took the trouble to examine with great care the directions for development issued by the different plate-makers, and he found, to his astonishment, that most of them altogether ignored the question of time of development, and not one of them pointed out that length of development led to increased contrast.

The lecturer next dealt with the subject of fog, and said that it was full of difficulty, and had not yet been thoroughly investigated. Even Messrs. Hurter & Driffield, with all their splendid labours in the cause of photography, had not got to the bottom of the question, and he could not pretend that he himself had been more successful. He had found that, using hydroquinone as a developer, fog presented itself in five minutes, and that when once it starts it continues to grow apace.

Next he dealt with the variations of different developers under three heads, namely, energy, multiplying factor, and speed, giving various tables to show the action in these respects of pyro, metol, ortol, adurol, kachin, quinol, glycin, and metol-quinol mixed. The most lazy density producing developer was rodinal, which may, under certain circumstances, take more than an hour to produce its full effect. All developers give the same amount of density provided sufficient time be given with each to produce its full effect. We must remember that it is the action of light which confers density upon a plate, not the agent by which the image is revealed. It is true that certain plates work better with certain developers, and some work much better if bromide be absent. This remark applies to Cadett's "Spectrum" plate, to Lumière's and others. At an early stage bromide lessens speed of development, and it induces a steeper gradation, but as the action is carried further, the addition of bromide is found to make no difference in the result. Bromide is useful under certain conditions, but he himself prefers not to use it. The time of appearance of the image is, in his opinion, the only guide to correct period of development.

Mr. Watkins concluded an admirable lecture by showing some beautiful pictures on the screen including several snapshots. The negatives of these he had never looked at during development, simply removing them from the dish when the period, calculated from the first appearance of the image, had elapsed. Many of the pictures had been exposed behind a Cadett screen.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, November 15, at eight o'clock "Lantern Luminosities," by Mr. R. R. Beard.

LECTURE ON ARCHITECTURAL PHOTOGRAPHY.—Mr. H. W. Bennett, F.R.P.S., will deliver a lecture on this subject before the Borough Polytechnic Photographic Society on Wednesday next, the 15th instant, at 8.30 p.m. Tickets of admission can be obtained of the Hon. Secretary, 103, Borough-road, S.E.

THE Process and Engineering Company, of 60, Gravel-lane, Southwark, S.E., inform us that they have purchased the business of the late Surrey Manufacturing Company, at 60, Gravel-lane, together with all rights, patents, and registered designs in the manufacture of dark rooms, studios, sinks, process cameras, and process-workers' machines, &c.

TRAILL TAYLOR MEMORIAL LECTURE.—The second lecture in memory of the late J. Traill Taylor will be delivered at the rooms of the Royal Photographic Society, 66, Russell-square, W.C., on Tuesday evening next, November 14, 1899, at eight p.m., by Major-General Waterhouse, I.S.C. The subject is "The Teachings of the Daguerreotype." Mr. A. Haddon will take the chair and admission will be free.

MESSRS. FURST BROTHERS, 17, Philpot-lane, E.C., inform us that they have added the following cinematograph subjects to their stock of pictures: 1st Battalion Rifle Brigade embarking on a.s. German; H.R.H. the Duke of Connaught and party (Sir Russell Baker and officers of the general staff) coming aboard to bid farewell; soldiers waving "Good-bye" as ship leaves; Union liner German departing (close view, showing soldiers).

## Patent News.

THE following applications for Patents were made between October 23 and October 28, 1899:—

CAMERAS.—No. 21,096. "Improvements in Magazine Photographic Cameras." F. H. ALSTON and THE BIRMINGHAM PHOTOGRAPHIC COMPANY (Limited).

LAMPS.—No. 21,097. "Improvements in Lamps for Photographic Purposes." F. H. ALSTON and THE BIRMINGHAM PHOTOGRAPHIC COMPANY (Limited).

HAND CAMERAS.—No. 21,098. "Improvements in Hand and other Magazine Photographic Cameras." F. H. ALSTON and THE BIRMINGHAM PHOTOGRAPHIC COMPANY (Limited).

ANIMATED PHOTOGRAPHY.—No. 21,127. "An Improved Method of Taking and Reproducing Animated Photographic Effects." H. DICKINSON.

DARK SLIDES.—No. 21,206. "Improvements in and connected with Photographic Cameras, Dark Slides, Film-carriers, Focussing Screens, and Adapters." H. MAJOR.

FILMS.—No. 21,241. "Improvements in Photographic Films and Cartridges." Communicated by A. W. McCurdy. Complete specification. W. P. THOMPSON.

CAMERAS.—No. 21,242. "Improvements in Photographic Cameras." Communicated by A. W. McCurdy. Complete specification. W. P. THOMPSON.

DEVELOPING, &c.—No. 21,243. "Improved Process of and Apparatus for Developing and Fixing Photographic Films." Communicated by A. W. McCurdy. Complete specification. W. P. THOMPSON.

SHUTTERS.—No. 21,246. "Improvements in Shutters for Photographic Cameras." P. WALLIS and E. F. WALLIS.

APPARATUS.—No. 21,251. "Improvements in and connected with Photographic Apparatus." P. BONNAMY.

X-RAY APPARATUS.—No. 21,267. "Apparatus for Enabling the Positions of Foreign Bodies Visible by the X Rays to be Located, and for Guiding the Operator in Searching for and Extracting the same." C. REMY.

APPARATUS.—No. 21,310. "Improvements in or relating to Apparatus for Taking and Exposing Photographic Pictures." Communicated by P. A. J. Gasse. A. J. BOULT.

REVERSED NEGATIVES.—No. 21,405. "A Means of Making a Reversed Negative by Direct Contact with a Negative." D. K. WHITOME.

APPARATUS.—No. 21,431. "Improvements in Photographic Apparatus." J. P. LEA.

PHOTOGRAPHS ON METALLIC SURFACES.—No. 21,414. "Improvements in and relating to the Reproduction of Photographic Pictures on Metallic Plates or Surfaces." G. S. BETTISON.

CAMERAS.—No. 21,510. "Improvements in Photographic Cameras and Changing Bags." M. NIELL.

CHANGING BOX (?)—No. 21,515. "A New or Improved Box for the Treatment of Photographic Plates, Films, and the like." R. E. FRASER.

REPRODUCTION OF PHOTOGRAPHS.—No. 21,597. "Improvements in and relating to the Reproduction of Photographs." O. FULTON and M. GILLARD.

ARTIFICIAL LIGHT.—No. 21,598. "Improved Means for Facilitating the Taking of Photographs by Artificial Light." Complete specification. C. BERNHOEFT.

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

November.	Name of Society.	Subject.
13.....	Bradford Photo. Society .....	A Night among the Flowers. W. H. Atkinson.
13 .....	Kingston-on-Thames .....	Demonstration: Gravura Paper. A. C. Baldwin.
13.....	Oxford Camera Club .....	Practical Hints on Mounting. H. Minn. —Some Points on Development. C. Rippon.
14.....	Ashton-under-Lyne.....	Mountaineering within the Arctic Circle. Mrs. Main.
14.....	Birmingham Photo. Society ..	Under the Sunny Skies of Greece. R. L. Impey, J.P.
14.....	Leeds Photo. Society .....	Lantern-slide Making. Godfrey Bingley.
14.....	Royal Photographic Society ..	Teachings of the Daguerreotype. Major-General J. Waterhouse, I.S.C.
15.....	Oroydon Camera Club .....	A New Method of Artificial Lighting for Portraits. W. H. Smith.
15.....	Hackney .....	Opening of Annual Exhibition.
15.....	Photographic Club .....	Lantern Luminosities. R. R. Beard.
15.....	Southsea .....	Exhibition of Animated Photographs with the Birtac and Biokam. L. Dyer.
15.....	West Surrey .....	Sensitising Paper. J. Bulbeck.
16.....	Darwen .....	Great Eastern Railway Slides: A Trip on a Norfolk River.
16.....	Leigh .....	Various Reducers. W. Hampson.
16.....	Liverpool Amateur.....	Mountaineering within the Arctic Circle. Mrs. E. Main.
16.....	London and Provincial .....	An Easy Method of Stripping Negative Films from Glass. F. Kellow.
17.....	Ashton-under-Lyne.....	Elementary Photography Class.
17.....	Croydon Microscopical .....	A Holiday Ramble in Italy. Philip Crowley.

## ROYAL PHOTOGRAPHIC SOCIETY.

NOVEMBER 7.—Lantern Evening.—Mr. Snowden Ward in the chair.

The inauguration by the Council of a series of lantern evenings received ample justification on Tuesday evening, when a large audience, which included many ladies, assembled to hear a lecture by Mr. J. J. Vezey (the Chairman of the Lantern Committee), with lantern slides from photographs by Commander C. E. Gladstone, R.N. The lecture itself was chiefly a description of the slides, but the latter were not only of great interest in themselves, as depicting quaint and beautiful features of old-world cities, but also displayed a high degree of technical excellence, and were received with appreciation and frequent applause.

Mr. VEZEY, before commencing his lecture, alluded to the formation a few years ago of the Lantern Society, in which he had taken a prominent part, but whose existence was not very prolonged. Since its demise, however, there had been a desire in many quarters that the exposition of lantern work should receive attention at the hands of some existing institution, and he had accordingly brought the subject before the Council of the Royal Photographic Society, who had readily agreed to the proposition that a meeting on the first Tuesday in each month should be devoted to this purpose. If the members of the Society and their friends supported the movement by their attendance and appreciation, no effort would be spared by the Committee to provide interesting and attractive subjects, and it was hoped that this new departure would tend to increase the already considerable inflow of new members to the Society, who would find a convenient and suitable scientific home at the new premises in Russell-square.

The subject of Mr. Vezey's lecture was

## SOME MEDIEVAL TOWNS OF GERMANY.

the places dealt with including Rothenburg, Nuremberg, Bamberg, Ratisbon, and Ulm. Rothenburg, described as a charming medieval town, with walls and towers, its houses being principally red-tiled and gabled, with Gothic churches and Renaissance secular buildings, was illustrated by views of its quaint *thors*, or gates, the Rathaus, the Hegerester's Haus (house of the gamekeeper), the Baumeister's, or architect's, house, the fountain of St. George and the Dragon, the church of St. James, with an altar of beautifully carved limewood dating from 1478, typical street scenes, and others. Nuremberg, one of the most remarkable and interesting cities of Germany, and full of remains of medieval architecture and quaint streets, afforded many fine subjects for the photographer, including the old palace or castle, founded in 1024, enlarged in 1158, and restored in the Gothic style, and fitted up as a royal residence in 1854-6, the churches of St. Lorenz and St. Sebald, the Rathaus, Peller's Haus and Court, views in the streets and squares and on the river, and the house of Albert Durer, who was born at Nuremberg in 1471. Several fine interior views of Bamberg Cathedral were shown, with many other interesting buildings in this ancient city, which enjoyed municipal privileges as early as 973, and all the choice bits of Ratisbon and Ulm were admirably reproduced, and described in a style calculated to make every archaeologist long to spend a holiday in rambling among scenes so crowded with historical and artistic interest.

A hearty vote of thanks was given to Mr. Vezey and Commander Gladstone for the excellent entertainment they had afforded.

## COMING EVENTS.

The next Ordinary Meeting of the Society will be held, at 66, Russell-square, on Tuesday next at eight o'clock, and at 8.30 Major-General Waterhouse, I.S.C., will deliver the second Traill Taylor Memorial Lecture, the subject being "Teachings of the Daguerreotype." At the next Lantern Evening (December 5, at Russell-square), Mr. Frederick H. Evans will lecture on "Lincoln Cathedral," and exhibit slides from his own negatives.

## LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 2.—Mr. P. R. Salmon in the chair.

Mr. R. P. DRAGE said that he observed that his remarks at a previous meeting regarding combined toning and fixing baths had been the subject of adverse criticism in this JOURNAL. We were informed that Hardwich had investigated the matter some forty years ago, but he thought that, in the light of present-day discoveries and advances, these should by now have been supplemented. He still thought there was much to be done by chemists in putting upon a definite foundation the use of combined toning and fixing baths, and laying down the essentials for permanent results. He also desired to see the preliminary washing of P.O.P. done away. It was not merely a question of saving oneself trouble. We had processes like bromide printing, platinotype, &c., where the prints are taken from the frame and put straight into the developer or other bath, and why not an analogous treatment for P.O.P.?

Mr. S. H. FRY agreed so far with Mr. Drage's desire to simplify toning and fixing processes as to say that it was the tendency and desire to improve upon photographic methods, which had made photography what it was at the present time.

The CHAIRMAN said he had tried, he believed, all combined toning and fixing baths, but had gone back to the use of the separate solutions.

Mr. Walter D. Welford showed a series of slides of Belgium, its chief cities and historical features. The pictures were taken during a visit made under the auspices of the South London Photographic Society, and under the leadership of Messrs. Welford and Slater, in the summer of the present year. The places visited included Antwerp, Malines, Brussels, Waterloo, Namur, Dinant, Ghent, &c., and the photographs, taken as they were by some twenty or thirty different people, with their different styles, showed a pleasing variety of subjects. There were some very good interiors of cathedrals and churches, snapshots of street scenes, figure studies and landscapes, and, on the whole, the display was of good quality and attractive.

## PHOTOGRAPHIC CLUB.

NOVEMBER 1.—Mr. Frank Haes in the chair.

## ANNUAL MEETING.

The minutes of the last Annual Meeting were read and confirmed.

Mr. H. P. Radcliffe and Mr. J. W. Wade were unanimously elected members of the Club.

The HON. SECRETARY read the Committee's report and balance-sheet for the past year.

The CHAIRMAN remarked that the members could be well pleased with the state of the Club, both financially and otherwise, and moved the adoption of the report and balance-sheet.

Mr. BRIDGE seconded the motion, which was put to the meeting and declared carried unanimously.

Mr. FOXLEW proposed the hearty thanks of the meeting to the officers of the Club for their labours during the past year.

Mr. HASTINGS seconded the motion.

Mr. BRIDGE supported the same, adding that, the special thanks of the Club being due to the Hon. Secretary, he wished to couple the proposed vote of thanks with the name of Mr. Stretton.

The motion was carried unanimously, and

Mr. STRETTON returned thanks.

## ELECTION OF OFFICERS.

Messrs. R. Child Bayley and E. W. Parfitt were appointed scrutineers, and the gentlemen named were declared duly elected:—*Trustees*: Messrs. F. A. Bridge and Frank Haes.—*Committee*: Messrs. E. W. Foxlee, H. Vivian Hyde, A. Mackie, Hans Müller, E. A. Newell, Hutton P. Smith, H. Snowden Ward, and Walter D. Welford.—*Curator and Librarian*: Mr. Chas. Wallis.—*Secretary and Treasurer*: Mr. W. R. Stretton.

**Croydon Camera Club.**—The weekly meetings, which have been somewhat interrupted by the Exhibition, were resumed on Wednesday, the 1st inst., with all their usual power of attraction, a very satisfactory attendance ensuing to hear Mr. HARRY WADE descend upon

## STRIPPING FILMS.

That the lecture was worth attention is, in a way, evidenced by the fact that the lecturer travelled all the way from Manchester to Croydon on purpose to deliver it, returning after it was over to the metropolis of cotton land. In the first place, a number of large and attractive prints, which stood all the tests of specialist criticism as regards technicality, were handed round just to show what the film is capable of. Next Mr. Wade dwelt upon the manifold advantages of this acceptable addition to the materials at the disposal of the amateur. To put them shortly, the new film is in every respect as reliable and easy to control as the glass plate. Unlike celluloid films, the stripping film has great keeping power and latitude, and is not liable to pinhole defects, nor insensitive patches, nor "electric" fog. As an indication of their portability, eight dozen quarter-plates may be posted for one penny. Impatient amateurs will be glad to know that they can, at one time and in one dish, develop a dozen or more negatives, one on top of another. Moreover, if the picture is not all that it should be, instead of stripping the film from its paper support, nothing is easier than to sketch upon the paper backing lights which the negative lacks, and thus produce a picture which, *perhaps*, beggars nature.

**North Middlesex Photographic Society.**—October 30, Technical Night, Mr. T. E. Cox in the chair.—Mr. J. MACINTOSH said a good way of making a full-size copy of an engraving, if a reversed copy was immaterial, was to expose through the print in contact with a sheet of bromide paper, giving about two and a half times the normal exposure required, and developing up until the image was nearly buried, and reduce the developed image with persulphate of ammonia, subsequently redeveloping in daylight, when a reversed positive print resulted. He found the fine lines reproduced much better by this method than by means of dry plates, although not equal to wet plates. He also mentioned the method of Mr. J. Holt Player of exposing bromide or Alpha paper to green or yellow light in contact with engraving, &c., the light falling on the back of sensitive paper, which was placed in close contact upon the engravings. Examples were to be seen at the Pall Mall Exhibition. Mr. F. W. Cox showed prints on Venus paper, Velox, and by Moss's process; half of each had been exposed for months to light and damp in a window, which was undoubtedly a severe test, as some of the prints showed signs of water having been upon them. They all showed more or less signs of fading except Velox, which might be expected to stand a severer test, being a development paper. Mr. Lawson, jun., showed a negative taken after a hailstorm, with some black wood railings in the foreground. A curious effect was noticed, in that the upright bars distinctly showed through the horizontal rail along the top. Mr. MUMFERY suggested it might be caused by a condensation of moisture upon them, greater where the rail was not in contact with the uprights, the greater thickness of which made a better non-conductor of heat. Several other curious experiences were related, and, after the prints of the "Foreground Foliage" Competition had been viewed, the meeting terminated.

**Leeds Camera Club.**—October 31, Special Meeting, the President (Mr. W. J. Warren) in the chair.—The object of the meeting was to settle the question of providing exclusive premises for the Club, which were to comprise lecture-room, reading and smoking-room, with a dark room, properly equipped with enlarging apparatus and conveniences for better photographic work. The rooms were to be open on other than the ordinary meeting nights. To enable the rooms to be properly fitted and comfortably furnished, a limited company was to be formed, with shares of 10s. each, of which 4s. per share was considered sufficient to successfully float the scheme, on an issue of 400. The Committee of Management and their friends were prepared to find the money, but it was deemed inadvisable for them to do so entirely, for, in order that the members should have some interest in the scheme, they were expected to contribute at least one-third. The subscription was to be raised to 10s. per

annum, and, as this was about 2½d. per week, with the advantages offered, it was thought little enough. It was thought also that a sufficient number would be ready to take up the matter, and, together with a large increase of membership as the result of the movement, it was thought the required outlay would be fully met. A circular was sent to each member, asking for his opinion on the matter, but nearly ninety of the members sent no reply. Of the replies received, seventy-five per cent. were in favour of the rooms and the increased subscription, but only a very small number of shares were taken up. As the effect was to throw the whole cost on the Committee, who themselves might next year be out of office, the officers could not proceed with the scheme. The apathy and indifference of the members was further manifested at the general meeting, when only twelve per cent. of the members, other than the Committee, were present. For some time the aim and work of the management have been to elevate the standard of the Club, both in itself and in its work. A syllabus second to none in the kingdom was brought out, and a great amount of unseen work and energy put into the Club, but it would now appear that what has been done has not the sympathy of a large proportion of the members, and this has manifested itself in many ways during the past few months, whilst the absolute failure of the scheme is felt to be a censure on the management. The President, two Vice-Presidents, Treasurer, Secretary, and certain members of the Committee have therefore resigned their positions; but, in order not to impede the work of the Club, or injure it in any degree, such resignations need not, if the members wish, take effect till the close of the Club's financial year ending December 31 next, leaving the new management four months' working programme arranged for.

**Edinburgh Photographic Society.**—November 1, Mr. A. Eddington, F.S.I. (President), in the chair.—Mr. J. LAWTON WINGATE, R.S.A., read a paper on PHOTOGRAPHY IN RELATION TO ART.

At the outset he dealt with the limitations of photography, while admitting its great power to reach millions and give information to millions on all sorts of subjects who would otherwise be uninformed. The lecture was listened to with much interest by a crowded audience. Messrs. PATRICK, HAY, and WANACK afterwards dealt with the salient features of the paper, and in doing so referred to the excellence of Mr. Wingate's work as a painter. Dr. H. SCOTT LAUDER, R.N., afterwards gave a demonstration of persulphate of ammonia as a new reducer. By skilful illustrations on the blackboard, and by specimens which were handed round the audience, Dr. Lauder showed it to be a most powerful agent for improving and correcting under-exposed and over-developed negatives. Messrs. BURNS, J. B. JOHNSTON, and the PRESIDENT took part in an interesting discussion which followed. Thirty new members were elected in the course of the evening.

#### FORTHCOMING EXHIBITIONS.

1899.		
November 10, 11.....	Royal Photographic Society. Hon. Secretary, Major-General Waterhouse, 66, Russell-square, W.C.	
" 10-19 .....	Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.	
" 15-17 .....	Hackney Photographic Society. W. Selfe, 70, Paragon-road, Hackney, N.E.	
" 20-25 .....	Longton and District Photographic Society. Thomas Mottershead, 43, Stafford-street, Longton, Staffordshire.	
" 27-Dec. 18	American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.	
December 7-9 .....	Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.	
" 11-Jan.1900	Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.	
" 27-30 .....	Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.	
1900.		
January 29-31.....	Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.	
April 3-7 .....	Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.	

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

### Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

#### LOAN SET OF BELGIAN SLIDES.

To the Editors.

GENTLEMEN,—On behalf of myself and Mr. William F. Slater as leaders of the Belgian Excursion, will you kindly announce that, in response to

several inquiries, the set of slides shown at the Royal Society on Saturday night last will be loaned out to any society desirous of borrowing them? The set consists of 200 slides, contributed by about twenty-three members of the party, and form not only a very varied evening's entertainment, but give a splendid idea of the scenes visited. Almost every class of subject is represented—cathedral interiors, monuments and sculpture, canal views, street characters, the great Van Dyck procession, native dog carts, and excellent landscapes. The slides will be accompanied by a full descriptive lecture. To cover various incidentals there will be a booking fee of 2s. 6d., and each Hon. Secretary will have to bear cost of carriage one way. They will be circulated in the same fashion as prize slides and other collections—going on from town to town, and endeavours will be made to ensure short journeys. Applications with fee must be sent to me, and a list of desired dates or days should be given. A full list will then be made out. My own services as lecturer may be secured if desired. Of course, those who apply early, subject to route or town, will stand the best chance of getting their own dates.—I am, yours, &c.,

WALTER D. WELFORD.

19, Southampton-buildings, Chancery-lane, W.C.

#### THE ECLIPSE PHOTOGRAPH AT THE R. P. S. EXHIBITION.

To the Editors.

GENTLEMEN,—It were much to be desired that Dr. Lockyer should not have neglected to have seen the picture, No. 357, in the R. P. S. Exhibition before writing to you. I have not seen his photograph, but I have seen a similar one, or rather a copy of one, taken by Mrs. Maunier and published in her husband's book. In both these cases the exposure is made when only a very small crescent of the sun had reappeared from behind the moon after the total eclipse at a place where it had been total. The Exhibition picture, on the contrary, is a picture at a place where there was only a partial obscuration of the solar disc—as a matter of fact, not more than a third of the sun's diameter is hidden in it—moreover, at every station on the line of totality in that eclipse the sky was clear, whereas in the picture in question the eclipse shows through a mass of heavy cumuli, which are well lighted.

If the reversion of the solar disc had stood alone, the cause would have been evident at once, though even then we could hardly have believed in the existence of an educated man who could believe that he had got a true representation, especially as he must presumably have seen the phenomenon he was depicting, and the slightest observation must have shown him the falsehood of his result.

If a photographer were to exhibit the portrait of a very fair lady, in which, while the background and accessories were well depicted, the face was a black silhouette, we should not accept such a picture as a representation of the original; that, however, is the nearest approach to a parallel to what has been done in this case, and I can only repeat that the picture in question is not a representation of an eclipse of the Sun, either at Quetta or at any other place whatever. I am quite certain that no competent observer will differ from me. The explanation as to how it came to be shown as such a picture is one I have no particular concern with; it is a glaring case of untruthful photography.—I am, yours, &c.,

J. F. TENNANT, Lieut.-Gen. R.E.

11, Clifton-gardens, Maida Hill, W., November 4, 1899.

#### THE COMBINED BATH.

To the Editors.

GENTLEMEN,—As the member (to whom you refer in your leaderette of November 3) who, at a recent meeting of the London and Provincial Photographic Association, "expressed surprise that photographic chemists had done so little to place methods of combined toning and fixing of P.O.P. upon a satisfactory basis," may I say that I have been a diligent student of photographic literature for many years, and also that, as executive officer for various photographic bodies for several years, I have been instrumental (to an extent) in the contribution of a very large amount of matter to the photographic press. Therefore I feel that your rebuke in my case is undeserved. But, gentlemen, as you know, at the L. and P. we have the reputation of having, for the last twenty years or so, materially assisted photographic progress—in fact, the Association may fairly claim to have been of more practical utility to photographers than any other existing photographic society in the country; and therefore, in bringing this combined toning and fixing question forward, I considered we could do some good.

On investigating the matter, I found the combined bath is largely used by professionals, although more expensive than the separate bath, while the big quantities of it that can be seen in ready-made-up solutions at the photographic dealers would almost lead one to believe that the vast army of amateurs never used anything else. In fact, at our last meeting, the manager of a large photographic stock warehouse stated that, in his opinion, if it were not for the combined bath, very few amateurs would use P.O.P. at all.

Many manufacturers give the formula for a combined bath with their papers, but they invariably add that they do not recommend the same for permanency.

Photography has progressed very rapidly of late years, and are we not justified in asking the Ilford Company or the Eastman Company, or our good friend Mr. J. B. B. Wellington, to investigate the matter and give us an up-to-date combined bath that we can safely use with the magnificent printing-out papers that they issue now.

With all deference to your remarks as to "saving of trouble," I would suggest that "labour-saving" is a question of the age; and, if we can dispense with those preliminary washings, and put our P.O.P. prints straight from the printing frame into the combined bath, without fear of deterioration, thus having no more operations than with the bromide or platinotype processes, a very great saving of labour and time will result, and a great boon will be conferred upon professional and amateur photographers.—I am, yours, &c.,

THE MEMBER OF THE L. AND P. REFERRED TO.

## "COSMOS" AND THE CORNISH CAMERA CLUB.

To the Editors.

GENTLEMEN,—Your correspondent, "Cosmos," under Jottings, referred to some remarks made by the President of the Cornish Camera Club at their annual meeting. The President is reported to have said "that, given the same material and circumstances, one man could get good results while another man got only unsatisfactory results."

The person who reported the meeting should have stated that the President was speaking about various makes of plates, and one make in particular which a member of the Society is very successful with, but the President was never able to get satisfactory results with them, although with another make he was very successful. On reading the sentence as reported, I quite agree with your correspondent "that you can discuss the fact for centuries, but you will never alter it."—I am, yours, &c.,

H. TONKIN, Hon. Sec. Cornish Camera Club.

22, Market-place, Penzance, November 4.

## CHEAP ENLARGEMENTS.

To the Editors.

GENTLEMEN,—Apropos of Mr. Drinkwater Butt's letter in your last issue, what is the status of our profession (!) generally, and photographers themselves in particular, coming to? What with the dealers' "ring" round their necks, and the philanthropic newspaper "cutters" at their throats trying to choke the very life out of them, I have wondered how long shall we wait before we wake to a sense of our exclusively servile position amongst the trades of our land. Is there one other that could be coolly and quietly subjected to such barefaced and barbarous boycotting (I say "barbarous" because of its "keen" and "cutting" nature)? I venture to think not. And what's the remedy? What can we do to prevent such impudent slaps in the face? Nothing at all individually. An occasional protesting letter in your columns (much as I admire and welcome it) is of little or no use unless it be to inspire photographers to act unitedly in a body, and with one accord, and not stand aloof from each other on egotistical ground—a quicksand that has sadly injured and is daily destroying our professional vitality. Is it not so? Haven't we evidence of it on every hand and side of us? And individually we are helpless. Only by amalgamation, and that of the most strenuous and energetic character, can we hope to stem the tide of these debasing forms of opposition and oppression, which are most assuredly dragging us and our beloved art down into the lowest strata of commerce. I repeat again, we can do nothing individually in the matter. Let us therefore be united, and even now, at the eleventh hour, endeavour to organize such plans and arrangements as shall at least modify or neutralise, if not entirely quash, all such unwarrantable and unfair forms of dealing and opposition.—I am, yours, &c.,

November 6, 1899.

A PHOTOGRAPHER OF FORTY YEARS' STANDING.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

E. Smith, 170, High-street, Lewes.—Photograph of Southdown House, Lewes.

H. B. Collis, Westgate Studio, Canterbury.—Photograph of group entitled "Members of the Royal East Kent Yeomanry on active service in the Transvaal, October, 1899."

LENSES.—The address of the agent is H. F. Purser, 33, Hatton-garden, E.C.

T. A. FALCON.—We are obliged for your letter, but we do not publish lists of photographs that have not been registered by our publishers.

STAMP PHOTOGRAPHS.—D. L. asks: "Will you kindly tell me whether special paper is used in the printing of stamp photographs; if so, where can I get it?"—No special paper is necessary. Any paper that will do for ordinary prints will do equally well for stamp portraits.

FORMULA WANTED.—C. CLARK says: "I want a good formula for making a gelatino-chloride P.O.P. that will keep white. I should be much obliged if you could tell me of one."—In reply: Barker's formula, given at p. 1040 of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1899.

COPYRIGHT.—ANXIOUS asks (1) if it is necessary to put the word "copyright" on the work you have registered before publishing? (2) "Could I claim damages against any persons who pirated my picture if the word 'copyright' was not on?"—In reply: 1. Not necessary. 2. Yes; decidedly.

VERY RAPID PRINTING PAPER.—W. G. H. asks: "Can you inform me if there is a paper that will print black in the course of two minutes by the rays from magnesium wire?"—Any of the bromide papers will do what is desired, but the prints will have to be developed. There is no printing-out paper that will fulfil the requirements, unless, indeed, a very large quantity of magnesium be consumed.

MAKING ALBUMEN PAPER.—PRINTER says: "Kindly inform me of the best method of making ready-sensitised albumen paper, that will keep good for a few weeks or months, that will give good prints and not spoil the toning bath."—By making albumenised paper, we presume you mean sensitising it only. If that is so, you will find a formula for that on p. 1048 of the ALMANAC for the current year.

PHOTOGRAPHING THE LEONIDS.—THE MAJOR says: "I should be much obliged if you would kindly let me know if it is possible to obtain a photograph of the (meteors) shooting stars that will take place this month. If I use an eight-inch focus stigmatic at  $f/6$  on whole-plate, to what extent is it necessary to expose to obtain an image on an instantaneous plate?"—In reply: Quite possible. See the article on the subject in another part of the JOURNAL.

FORMULA WANTED.—DEVELOPER says: "I have the same trouble as other of your correspondents at this time of year, viz., late sitters, most often young children and family groups, and I have great trouble in getting printable negatives. Can you oblige me with the formula of the best developer for getting the most detail in the plate?"—It is claimed for some of the newer developers, such as kachin, ortol, metol, &c., that they will bring out more detail than some of the older ones. But it is obvious that, if the negatives are so much under-exposed that the light has not impressed the shadows at all, no developer can bring out detail in them. Try the above.

RUBBER STAMPS.—STAMPS says: "Would you kindly inform me how rubber stamps are made? Can I obtain any book of instructions? I am experimenting for the purpose of making relief stamps by a process of photography, and wish to make the stamps myself."—The method of making rubber stamps would take up too much space to describe in this column, and, moreover, the subject is not a photographic one—or one of interest to our readers. We know of no book on the subject. Messrs. Richford, Snow Hill, London, are makers of rubber stamps, and they will probably make what you require. If you were to make them yourself, you would require a vulcaniser and other appliances.

TONING TROUBLES.—J. S. says: "I wonder whether any one can explain why my last batch of prints are in two colours: the sea is pale blue, and rocks on each side are dark brown, the effect being much admired by all who see them. Paper is Eastman's Solio, whilst the combined toning and fixing bath was made by myself from *Barnet's Book of Photography*, p. 184 (the first of his list) only I left out table salt, and the gold was solution of chloride of gold; as prints were slow in toning, I added more solution of gold to bath, and was greatly surprised to find two colours in all of them."—This is a case of double tones. The formula, as given in the book, should have been adhered to, and the gold not added while the prints were toning. The gold should have been added some time before the bath was taken into use.

LANTERN QUERIES.—A. GREGSON says: "I have often seen it mentioned in LANTERN articles that the focus of a condenser should suit the focus of the objective, but I do not remember seeing it stated what particular focus of condenser should be used for any particular lens, therefore I should be glad to have an answer to the following:—1. How and by what method is the focus of a condenser to be found to suit any particular lens? 2. What condensers are best suited for a lens of six-inch focus, and one of ten? 3. Is there any work dealing with this part of the subject, i.e., the optical part? 4. How often should a lime be turned when used with a blow-through jet? 5. How much oxygen gas will a good blow-through jet use in two hours?"—1. 2. 3. Taylor's *Optics of Photography*, published by Whittaker & Co., will give the information desired. 4. As often as it is found necessary. Some limes require more attention than others. They should be watched and not allowed to burn into holes. 5. That all depends upon the orifice of the jet—from four to eight, or more, according to size and pressure.

**NEGATIVE FROM A PRINT.**—A. C. R. says: "I wish to make a negative from a print, will you kindly tell me how I can copy same size? I have a Lancaster's half-plate camera, also a Lancaster's enlarging camera, enlarging up to  $10 \times 8$ ."—If the camera will extend to double the focal length of the lens, the negative can be made direct, the print being placed at the same distance from the lens as that is from the ground glass. If the half-plate camera is not long enough for that, the best way will be to make a small negative and enlarge it in the enlarging camera.

**COPYRIGHT; INTENSIFICATION.**—COPYRIGHT asks: "1. If a photographer takes a view for which he does not receive payment, but which he does not register at Stationers' Hall, and finds that the photograph has been copied, if he then registers it, can the copier be proceeded against (a) for selling the copy of photograph before registration; (b) for selling copy after registration? 2. When intensifying negatives, I sometimes find a brown patch resulting after the negative is washed and dried and ready to print. This occurred on a negative which was intensified in feeble daylight, and the intensifier was acidified with HCl, and previous to intensification the negative was soaked in a weak solution of HCl. What is the cause of the brown patch?"—In reply: 1. It is doubtful if damages could be recovered in the case of (a), but, as regards (b), an action would undoubtedly lie. 2. Probably the hypo was not thoroughly removed from the film.

**VARIOUS.**—"ONE WHO WANTS TO KNOW" asks: "1. What are the duties of a studio and dark-room assistant? 2. In developing with pyro ammonia, I get a lot of green fog. Can this be avoided? I use Ilford plates. 3. Are there any books published on the following subjects, where are they obtained, and the price: Lighting and posing; the uses of swing back and rising front in cameras; working up plates, and printing and developing them; and one on lenses, explaining which to use for various subjects, and also explaining the use of stops?"—1. To develop negatives and to assist generally. 2. You ought not to get green fog with these plates. Try pyro soda, or some of the newer developers. 3. A work on lighting and posing is published by Dawbarn & Ward, Farringdon-avenue; *Platinotype*, by Abney (Piper & Carter, Farnival-street). Working up the prints. No special work on the subject. Taylor's *Optics of Photography*, published by Whittaker & Co., will give the other information.

**DISPUTED AGREEMENT.**—AGREEMENT says: "I contemplate opening a small first-class business in Prestwick, a few miles from Ayr, N.B., but in the county of Ayr. Now, three years ago I was employed by a firm at Ayr, and signed an agreement for three years, and in it was a clause not to work for any other photographer in the county, or start a business for a period of seven years from the natural termination of agreement. Well, before the first year had elapsed things were very unpleasant, and I wished to get back to London; so we both agreed to acknowledge the agreement void, and leave amicably, which I did. I might also state that there was another clause in which it stated, should either party break the agreement before the three years were up, we were both liable to a sum not exceeding 70*l*. Do you think that, after stating these facts, there is anything to fear from that agreement?"—The agreement should have been cancelled at the time you arranged to leave. If it was not, it is still in force, though, under the circumstances, we do not think it would have much weight in a court of law. However, we should recommend you to take the advice of a solicitor on the matter before you do anything further.

**DISPUTE WITH SITTERS.**—VERAX says: "Will you kindly inform me what is the legal position of photographers in such cases as the following:—A lady comes to my place and makes an appointment; on the day appointed she sends two of her daughters to be photographed together and separately. I take a number of photos in cabinet and *carte-de-visite* sizes, and send proofs (ten), mounted and finished. They are good photos. The lady brings them back in a day or two, and says she doesn't like any of them; they are 'caricatures.' I ask her to send the young ladies again for another sitting. She replies, 'I don't know, it is too much trouble.' Nothing was asked as to my charge or prices of photos. Am I entitled to charge for making the ten negatives? And in making out a bill would you advise that I should simply charge for making ten negatives, and say nothing about proofs (as they were all returned), or charge as, 'For work done to order,' so much?"—Evidently the portraits were not good, or the lady was very difficult to please. We should say your best plan would be to send back, say, two or three of the portraits and make your regular charge for them. If you charge for taking ten negatives, they will become the lady's property. If you, as some photographers do, put on your price list "satisfaction guaranteed," we suspect you can make no charge at all, as the portraits are not satisfactory to the sitter.

**BACK NUMBERS OF THE JOURNAL.**—H. B. writes: "Will you kindly tell me how I can best procure the back numbers of your JOURNAL which treat of the making of emulsions (the experimental work). Nothing is now said about it, and when I first took in your paper the subject was dying out. Will you kindly say what years would be best, whether I can get them on hire from your office; if not, whether on sale, and at what price? I would rather have them on hire, as I only want to read them and return. If not procurable through your favour, I must advertise in your list. I have read all Abney, &c., but there are many points which are either only assumed or not touched, and I might gather what I want from the multitude of councillors." In reply: The numbers and volumes in question are long since out of print. We should recommend our correspondent to advertise for the volumes for the years 1879-1885 inclusive. These will give him practically all the information available on the subject.

**STAINS ON PRINT.**—COLLODION says: "I should esteem it a great favour if you would kindly inform me the cause of the yellow stains showing in matt surface print I now herewith send you. It is printed, and toned with platinum and gold baths and fixed according to instructions given, it is a matt surface collodio paper print. We hand-wash the prints for fully forty-five minutes and then about thirty to sixty minutes in running water to finish up. This print was returned to me yesterday, only being a fortnight sent home to my client, it is one out of a dozen supplied, and he is wondering if the rest I supplied will go the same way. I have never been troubled until now with these spots, but our branch studio at Strathpeffer has been troubled with yellowish marks like what I now show, but they do not appear for some days after mounting. Every care has been taken in keeping baths clean and pure and up to strength; of the mount I do not think there is any fear, but I shall be glad if you can find out cause or give me any indication as to what might be probably the fault, if any, on our part. There have been a few small reddish spots also like size of pinhole on some of prints done lately."—The stain appears to be due to imperfect fixation, i.e., the prints being allowed to stick together while in the fixing bath, so that the hyposulphite of soda did not have free action at those parts where the stains appear. More care in the fixing operation will avoid them in future, we have little doubt.

**A BUSINESS MATTER.**—DIFFICILIS says: "Last year I purchased a business, a clause in the agreement of the purchase being, 'Mr. — will sell and Mr. (W.) — will purchase at the price of — the goodwill and business of Mr. — as photographer as carried on by Mr. — at —, and all the cameras, lenses, negatives, photographic apparatus, accessories, appliances, and materials, and such of the other contents of the studio, changing room, reception room, and dark room at — aforesaid as appertain to the said business, but exclusive of any private, household, or domestic furniture or other articles which may not have been used by Mr. — for business purposes only.' The purchase was completed, and I entered into possession. I had been told that everything was in order, but soon discovered, on repeat orders coming in, that some of the negatives, at any rate, were out of place, and several times I had to ask the assistance of my predecessor in finding them. Later, I discovered signs that many were missing altogether, and for several months past I have been devoting all my spare time and that of an assistant to putting them in order and checking them. I have just completed the work, and find by the books and negatives as follows:—

Number of negatives in books (approximately)	2984
Number of negatives missing:—	
1/2 plates (approximately)	61
2/3 " "	100
1/4 " "	3
1/8 " "	20
1/16 " "	12
Uncertain sizes	148
Total missing	344
Number of negatives on shelves	2640

\* I have classed these 'uncertain sizes' because, for some time after the business commenced, cabinet, *cartes-de-visite*, and midgets, appear all to have been taken on half-plates, and in some later instances sizes are not given in book. Will you kindly give me your opinion (a) as to whether I have or have not a claim against my predecessor for the missing negatives, a very large proportion as you will see? (b) As to the valuation of the missing negatives. I ought to say: (a) That I do not wish to make any exorbitant claim; (b) That I have actually been unable to execute orders in one or two cases already for copies from negatives that are on the books but not on the shelves; (c) That the business was commenced by my predecessors themselves about four and a half years ago; (d) That the figures on previous page only include negatives up to the time of my succession. I shall further be glad of your opinion on another point: My predecessors took several negatives of one another (i.e. husband and wife), and of their children. Some of these were certainly used for business purposes, e.g., an enlargement from one of them was made and hung in the reception room, where it still remains. To whom do these negatives belong, to myself or my predecessor? (See copy of clause in agreement on p. 1.) I forgot to say that the negative specially instanced above, and others as well, were also used for preparing prints for the show-cases, in which some of them were still at the time of my incoming. My predecessor begged some of these prints (i.e., from the cases) from me when I changed the cases—*begged*, not *claimed*.—We are a little doubtful if you could sustain any claim, unless you can show that your predecessors removed these negatives, and are now making use of them for business purposes. There does not appear to be any definite number of negatives mentioned in the agreement. Some may have been broken, and others lost, or many other things—sold to the sitters, for example. The number of missing does not appear to be, under the circumstances, in a business of four and a half years' standing, very excessive, after all. The family portraits, the negatives of which you think you ought to get, were clearly not taken for business purposes, though some of them might have been used as specimens. We do not think you are entitled to these. You must excuse us saying that we think you are a little unreasonable in the matter.

\*. Several answers to correspondents are unavoidably held over.

## EX CATHEDRA.

A PROCESS of printing with phosphate of silver, as was seen by our last week's issue, has been patented by Dr. Johannes Meyer, of New York. In his specification the Doctor says, "The silver phosphates have so far not been employed for photographic or other purposes, and the only mention of any application made of them is to be found in *Hardwick's Manual of Photographic Chemistry*." He writes: "other insoluble salts, such as the phosphate and citrate, render the paper more sensitive than when it has been treated with a soluble salt of silver only." Evidently, Dr. Meyer is not aware that a phosphate of silver printing process was published in this country something like fifty years ago, which is not materially different from that which has just been patented.

It was invented by Dr. Fyfe, and is thus given in Hunt's *Researches on Light*, published in 1854: "The paper should be soaked in a solution of phosphate of soda, and then dried, after which the nitrate of silver is spread over one side of the paper by a brush; the paper is again dried, and afterwards

put through the phosphate, by which any excess of nitrate of silver is converted into a phosphate. Although papers thus prepared answer exceedingly well for copying by application, they do not change so readily as to render them of any use in the camera obscura. One advantage possessed by these phosphate papers is the readiness with which they are fixed by the application of a weak solution of ammonia. . . . Dr. Fyfe recommended the application of the precipitated phosphate to paper, glass, or metal, in the form of a paint, and, if this is carefully done, some very pleasing effects are to be produced." It will be noted that Dr. Meyer claims that his solution or emulsion can be spread over almost any surface like a paint, and mentions paper or other material, such as wood, celluloid, lithographic stone, silk, cotton, or other textile fabrics, and other materials.

\* \* \*

It will be interesting to quote a little more from Hunt on this process: "After the phosphate has been darkened by exposure to sunshine, it is very readily bleached by the joint agency of the solar rays on the iodide of potassium. This was the process published by Dr. Fyfe for producing positive photographs by one application at a very early period. Other processes were found, however, to give much more satisfactory results, and it is now but seldom used." Here we have proof that the phosphate process had been used in practice. It is also noteworthy that Hunt, writing in 1854, says that Dr. Fyfe's method was published "at a very early period." Verily there is nothing new under the sun, particularly in connexion with photography, as is evidenced by the many rediscoveries made from time to time of the older processes and the patents obtained for them.

\* \* \*

THE above rediscovery of one of the oldest processes of printing exemplifies what we have more than once said, namely, that experimentalists and would-be discoverers would do well to give attention to some of the older processes of photography in conjunction with modern knowledge of the principles upon which they are based. The outcome would probably be that some very useful processes might be evolved and with great credit to the investigator.

At the review of the Life Guards on Saturday, by the Queen, when she wished them God speed and a safe return, the ceremony was photographed by Messrs. Russell & Son, by command; and the report says that Her Majesty did not desire the cinematograph to be used. Now, in cases where the Queen "does not desire" a thing to be done, it is generally understood that she objects to its being done. Be that as it may, a series of pictures representing the review of the troops, whether they were obtained surreptitiously or otherwise we do not know, were shown at the Palace Theatre the same evening, and received with the greatest enthusiasm. The films, we are told, were developed on the return journey from Windsor. The fact that the pictures were obtained, and the films developed, and the transparencies made from them, and exhibited on the screen within a few hours, shows a degree of photographic enterprise little dreamt of a few years ago.

\* \* \*

QUESTIONS have more than once been asked in the House of Commons with reference to the absence of Röntgen-ray apparatus in previous campaigns, and the replies have referred to the difficulties attendant upon its transmission, &c, and that in no case had a wounded man suffered from the absence of the Röntgen apparatus, and the like. Some of us, however, may have ideas that differ from those who gave such replies. It must be useful on any battle-field where rifles and artillery are used. It is therefore satisfactory to know that the Army Medical Corps, now on its way to, and arriving at, the Transvaal are provided with the necessary appliances. We read that the Duke of Newcastle, who, it is well known, is an enthusiastic photographer, is bearing the entire expense of the fitting out of the hospital ship the *Princess of Wales*, and, of course, the necessary Röntgen-ray apparatus will not be omitted. We also learn that a private donor has undertaken to provide a complete Röntgen-ray and photographic apparatus for the hospital ship *Spartan*. If, up to the present campaign, the War Office have ignored the value of Röntgen's discovery, they are now alive to the fact it is very valuable. Thanks are assuredly due to those donors who have provided it for the hospital ships at their own cost.

\* \* \*

COMMANDER WELLS, R.N., the Chief of the Fire Brigade, reports that a serious explosion occurred at Dalston last week, during a display of fireworks, in which seven persons were injured, four so seriously as to necessitate their immediate removal to the hospital, through the explosion of about six pounds of chlorate of potash. Up to recently, chlorate of potash was thought to be, by itself, a perfectly harmless material. It is perfectly true that explosions, sometimes fatal, did occasionally occur when lanternists had, perforce, to make their own oxygen, but then the cause was always attributed to the chlorate containing some carbonaceous matter. This, if we mistake not, was the decision when one of the Messrs. Wrench was unfortunately killed some few years ago while making oxygen. Some little time back, when there was an explosion at the chemical works of the United Alkali Works at St. Helen's, and five persons were killed, and the surrounding buildings were wrecked, the same opinion was expressed.

\* \* \*

THIS appears now to be a fallacy, for in his report on this catastrophe, issued a few days ago, by Col. A. Ford, Her

Majesty's Chief Inspector of Explosives, he says that, so far as he has been able to ascertain, an "explosion" of potassium chlorate had hitherto been unknown in the United Kingdom or in any other country. But, in order to further test the matter, experiments were carried out, with the result that it was found that the salt, after all, is liable to explode under certain conditions. The Colonel adds that it cannot be doubted that the explosion at St. Helen's of a small portion of the chlorate took place, this portion being, doubtless, raised very rapidly to the required temperature by the intense heat caused by the burning empty kegs. At present photographers and lanternists, as they can get their oxygen ready-made, are not so interested in chlorate of potash and its properties as they were formerly when they had to make the gas for themselves. Still it should be borne in mind, by those who are yet compelled to make their own oxygen, that the chlorate of potassium is not the harmless material that it has hitherto been considered—that is, when used under certain conditions.

\* \* \*

In reference to an apology published in the advertisement columns of the present issue of this JOURNAL, the Britannia Works Company, Limited, inform us that, this being the first case of a breach of the rules brought to their notice, they wished to treat it leniently. They add that, in all future cases, the action will be carried into Court, and the fullest penalties and costs will be insisted on.

\* \* \*

It is understood that amateur photographers will receive excellent treatment at Paris. The French Commissioners have made a ruling concerning the taking of pictures at the Exposition. Cameras will be allowed on the Exposition grounds after a permit has been secured from the Exposition authorities. A charge of ten centimes will be made for this, and the applicant will be required to furnish his name, age, and other personal data, together with his residence in Paris. Only the buildings and general groups can be taken. Photographs of individual exhibits will not be allowed, as the patent laws of France guarantee the patentee against photographs of articles exhibited.

## PICTORIAL PHOTOGRAPHY.

THE case for pictorial photography, from the Salon point of view, is very ably and clearly presented by Mr. Alfred Steiglitz, in the current number of *Scribner's Magazine*. His contention is, that photographic tools being "pliant" ones, and not "mechanical tyrants," granted a technical knowledge of their use, supplemented by an all-important supporting buttress of true artistic feeling and knowledge of composition, photography can rise to heights of expression approximating in kind and merit to that of the artist. Dr. Emerson is quoted in support of the points, to the effect that "the painter learns technique in order to speak, and considers painting a mental process. So photography, speaking artistically, is a severe mental process, and taxes all the artist's energies even after he has mastered technique. The point is what you have to say, and how to say it. That our technique is more difficult to learn no one will deny; but the greatest thoughts have been expressed by means of the simplest technique—writing." The necessity for artistic feeling is, of course, readily granted in all photographic work worth looking at, except in such exclusively mechanical directions as taking machinery, and so on,

where very conceivably its possession might militate against the desired result. So is the necessity for a thorough knowledge of technique, otherwise of photographic tools, and the best way of using them; but that those tools are "pliant" ones comes confusedly with the shock that Mr. Steiglitz, in the course of his article, anticipates will be the case "to many who have tacitly accepted the popular verdict to the contrary." That photographic tools have a certain range of working no one will deny, nor that the range is directly proportionate to the capacity of the worker. That the range can be more specially utilised for the accomplishment of a particular object, and to great advantage, pictorial work for instance, is also clear. One worker, by his superior knowledge of what form of lens to use, how and when to use it to greatest advantage, his further knowledge of developing and printing, can turn out a very different result to one less capable. This, however, is not pliancy of tool, but knowing how to get full value out of it.

The tool is very stiff and unyielding, and very soon, by comparison with others, such as the artist's pencil or brush, cramps the action of hand using it however skilful it be, and the directing brain however capable. The very essence of photography is its truth, and that truth is immediately dependent upon the narrow margin allowed by the severely mechanical nature of the tools, and the use made by their means of stiff, unbending optical laws. We are very fond of exalting this prime feature at need in calling attention to the correctness of detail, texture, and form of a photographic representation, and it can hardly in reason be claimed for photography that it forms an exception to the universal law that no means can rise to excellence in accomplishing diametrically different effects. Yet this is what is done when the photographer's picture is put so prominently forward for comparison with that of the artist. The artist would not pretend to be able to turn out anything of photographic truth and detail by means of brush and pencil, even were he desirous of doing so. The chief cause for the opposite lack of modesty—or better, perhaps, the lack of appreciation of the broader proportion of things—on the part of the photographic worker, paradoxical though it may seem on the face of it, is really highly creditable to him, viz., so keen a feeling for the artistic side that he wishes to express it in a better way than the orthodox photographic print. One always feels rather sorry, in a case of this kind, that instead of wasting so much high effort in such misdirected ways as straining a lens beyond its power, piecemeal developing, and dodging light in printing, the more suitable methods of the artist have not been taken to. It is as though a mason were trying to carve wood with his chisels, or, *vice versa*, a carpenter blunting his tools upon stone. If one craves for the work of the other, why not change places and tools? Mr. Dallmeyer, in a small pamphlet upon lenses, what they are expected to do and what they cannot, very aptly gives one item of the latter as the inability to register a result identical with so peculiar a lens, "physiologically and psychologically," as the human eye.

This exactly hits off the cause of the superior excellence of the artist's work. His is an effort more or less good in the opinion of the critic, as his physiology and psychology is more or less like those of the artist, to express the desired subject as he sees it, and with the feeling of excellence he attributes to it. His method admits of it, the photographer's does not. What comparison in terms of labour and brains can there be between an artist, with his pencil or brush, and a photographer with his camera, setting about the picturing of a landscape scene for

instance? We will admit that their appreciation of the scene is equally keen and equally artistic. One, after carefully seeing that all the mechanical conditions necessary to success are all right, uncaps his lens, or presses his pneumatic bulb, and the thing is practically done. The other, after taking the same pains in seeing that conditions of light, point of view, and so on are favourable, has not started with his work. Instead of having it mechanically done for him in a second or two, he has to select here, reject there, turn different values and impressions loose in his brain and fancy, mould them to the expressing point that long practice and diligent study have educated him to regard as practicable and pleasing; but that is only half the work, less than a half, execution remains; the correct rendering of form, perspective, and light and shade; the capacity for doing which he has acquired in a far different and more laborious fashion than the photographer has that for handling his camera. What it really does mean it would do many photographers priding themselves upon their accomplishments in exposing, developing, and printing, a great deal of good to go in for it only in a minor experimental fashion; and which is the more likely to give satisfaction as a finished result—the sketch with brains behind each pencil stroke, and the scene carefully studied before each is put down; or the print which the photographer brings out in the obscurity of the dark room by "brush development, forcing here, restraining there, keeping all the while a proper relation between the different parts that the whole may be harmoniously in tone?"

It reads uncommonly well, it must be admitted, and so does the further statement that "the plasticity of the whole processes is such that, with the actual beauties of the original scene and its tonal values ever before the mind's eye during the development, the print is so developed as to render all these as they impressed the maker of the print." But will it work out? The trained artist will not admit that it will often indeed expresses with marked emphasis his conviction to that effect. Mr. Steiglitz, on the other hand, says it will, and honestly believes it, for his article has the stamp of genuine enthusiastic conviction about it. Further, he submits half a dozen pictures, presumably made by the means he advocates, in proof of his point. The pictures are good, show a keen artistic feeling, but are ones that could certainly be produced by the ordinary use of photographic tools, possibly to greater advantage. The secret of their success is due more to the judicious selection of subject, that in the absence of obtrusive detail offers a pleasing suggestion to the imagination, emphasised by the well-selected titles to the same end, than to any special method of working. Comparing the pictures with those which an artist of such capacity in his particular direction as the photographer is in his would produce of the same subjects, it may very safely be said that the artist's would be immeasurably superior. The simplicity of the artist's tools leaves an inevitably larger place for the exercise of brains and deft manipulative skill. The essentials that from the creation of the world, or at least that point in the history of the world at which they became recognisable quantities—the first sketch of the mammoth on his horn by the hunter who had killed him maybe—have commanded, and justly, the highest place and deference. That this instinctive paying of respect is a true one, and capable of very much wider application, may be argued from the superior place universally given to a "hand-made" article over the "machine-made" one—at bottom a tribute to what best deserves honour, active brain power.

**Aqueous Solutions of Metallic Gold.**—R. Zsigmundi has lately given a detailed account of a method of preparing a solution of metallic gold in water, a sufficiently wonderful achievement when it is remembered that in the middle ages a method of dissolving gold in any medium whatever was the perpetual quest of the alchemists, they being under the belief that, once found, they would possess an *elixir vite*. We are not aware that such a solution will have any direct photographic usefulness, but gold plays such an important part in all prints with a silver basis that it is impossible to foretell where its functions will end. Zsigmundi makes 25 c. c. of a solution of ordinary acid chloride of gold of the strength of 0.6 gramme per litre, and dilutes it with four to six times its bulk of distilled water, and 2 to 4 c. c. of a decinormal solution of carbonate or bicarbonate of potassium. After bringing the mixture to boiling point he adds carefully and rapidly 4 c. c. of a one per cent. solution of formic aldehyde (formalin) freshly distilled, and stirs the whole of the time. The solution, at first colourless, quickly becomes a brilliant red. This solution, containing 0.005 per cent. of gold, can be boiled or kept several months without change. He arrives at the conclusion that the gold is not in the form of minute particles of metal in suspension, but is a true solution.

**The New Radio-active Element.**—This substance, recently referred to by us, is described in the *Chemical News* in a short article by its discoverer, M. A. Debiere. M. and Mde. Curie's experiments had already enabled them to discover in pitchblende two new substances, elements which they termed polonium and radium, bodies possessing far greater radio activity than the chief constituent of the ore, viz., uranium. M. Debiere states that the new metal (still unnamed) has chemical properties entirely different from the above named two, and is different also in regard to the radio activity. The former are spontaneously luminous, while the new metal is not. It is probable that eventually it may come to the front in radiation experiments, but, up to the present time, the small proportion in which it is present virtually bars the way to extended experimental work. To obtain the small quantity he experimented with, he had to work upon several hundredweights of the raw material. He estimates its radio activity as 5000 times that of uranium, at one time considered a very remarkable body as regards the Röntgen-ray-like power of its radiations.

**The Action of Light on Silver Iodide.**—In a German technical journal Herr H. Scholl writes upon the action of light upon iodide of silver, *per se*, and, when backed with a layer of metallic silver, the latter being the condition of a sensitive Daguerreotype plate. In the first case, as instanced by a silvered glass exposed to iodine vapour, the unexposed iodide is clear, but, when acted upon by light, cloudy. Herr Scholl shows this action is simply a mechanical alteration, the change requiring the further catalytical action of some oxidising agent, such as oxygen or iodine; but in the second case, iodide upon a surface of silver, chemical action takes place iodine is liberated, and it combines with the silver surface by above catalytic action, accelerating the change. The capability of development of the Daguerreotype plate is due to this change and the presence in the surface layers of reduced silver; it extends through the whole thickness, and is throughout proportional to the light intensity at the surface.

**Anti-mould Reagents.**—In an article by Mr. J. F. Clarke on an electric aspect of anti-fungi toxins, some useful hints as to the action of various chemicals can be obtained. The presence of mould too often makes its influence felt in an unpleasant manner in many photographic processes and preparations. Thus, gelatine and flour pastes are peculiarly liable to the attacks of mould, and gelatine prints are by no means free under suitable conditions, while solutions, such as of citric acid, &c., quickly become cloudy from the presence of fungus-like bodies. But many of the gelatine preparations in use in photography possess their own antidote. For example, potassium chromate and bichromate have a strong toxic

action, and come closely after either potassium cyanide or nitrate of silver. In the same category are found mercuric chloride and nitrate of silver, and formaldehyde or formalin, while the mineral acids—hydrochloric, cupric, and sulphuric—have a very low toxic power upon fungi.

**Removing Lime and Magnesium from Natural Waters.**—It is well known that some waters are so contaminated with these earthy matters as to militate against their use in photographic work, but a paper by Mr. Martin L. Griffin in the *Journal* of the American Chemical Society gives a *résumé* of the best way of removing these substances. For carbonate of lime the most effectual agents are caustic soda and fluoride of sodium, and, in certain cases, aluminate of sodium. Waters containing a large proportion of carbonate and sulphate of lime can be successfully treated in the same way. Caustic baryta is not so good, but is effectual for magnesium salts, though the caustic soda treatment is slightly better.

### THREE-COLOUR TRANSPARENCIES.

M. LÉON VIDAL, the well-known editor of our contemporary, *Le Moniteur de Photographie*, describes the following method of preparing trichromatic transparencies by the superposition method in the *Bulletin du Photo-Club*.

Three negatives are obtained, one for the red rays, another for the green, and the third for the violet.

The taking screens are made as follows:—

*The Reddish-orange:* Yellowish eosine, 2 parts; naphthol yellow, 1 part; water, 100 parts.

*The Green Screen:* Sulpho-green I., 2 parts; naphthol yellow, 1 part; water, 100 parts.

*The Violet Screen:* Methylene blue, 2 parts; Paris violet, 2 parts; water, 100 parts.

Filter, and allow the plate to be coloured to soak for five minutes, rocking the dish all the time.

Ordinary dry plates, fixed in hypo and well washed and dried, may be used, but they must be placed next the plate.

Lumière's panchromatic plates may be used, but orthochromatic plates, specially sensitive to red, to yellow, and the ordinary plate, may be used equally as well.

In order to obtain the transparencies thin, rollable celluloid films should be used, and cut to the required size, and immersed for two minutes in a bath of bichromate of potash, 0.75 per cent., and then dried in the dark. They should be exposed behind the negative, with the negative in contact with the film, and require from five seconds to two minutes in direct sunlight, but it is preferable to use an actinometer.

Development should be effected in hot water at about 40° to 50° C., and then the silver bromide should be dissolved out by clean hypo, and the film well washed.

For the blue film methyl green should be used; for the red, erythrosine; for the yellow, a mixture of yellowish eosine and naphthol yellow. The films should be soaked in these solutions till of the desired intensity, and then, when dry, they may be fitted together.

### THE COLOURING OF LANTERN SLIDES.

In the *Bulletino della Soc. Fot. Ital.* Roster points out that in colouring slides the best results are obtained with aniline colours, and that it is important that the colours should not destroy one another, and he suggests the following as satisfactory. *Blue:* Indigo carmine. This is the best colour for the sky. *Green:* (a) Malachite green. This is very brilliant, and must be sparingly used, and it is difficult to spread it evenly on large surfaces, and it is not suitable for plants and foliage. (b) A mixture of tropælin O and indigo carmine is the best for foliage, and, according to the proportion of these two, a cold, a brilliant, or a yellowish green is obtained, and also the colour of dead leaves. *Yellow:* (a) Tropælin O for bright yellow, mixed with eosine it gives flesh tints. (b) Mixtures of tropælin O and orange for darker and golden yellow. (c) Orange alone. *Red:* (a) Eosine for a bright red. (b) Mixture of eosine and orange for brilliant fiery red. For *Brown:* (a) Bismarck

brown or vesuvin; the former is to be preferred for warm brown tones. (b) Mixtures of Bismarck brown and indigo carmine for cold brown tones.

The separate colours, as well as the mixtures, may be kept in stock in stoppered bottles. A retouching desk should be used with a sheet of white paper as a reflector, and the plate slightly tilted. The reflector should be about four inches from the plate.

The transparency should be allowed to thoroughly soften by soaking in water for half an hour, then blotted off with blotting paper, and placed on the retouching desk. The colours should be applied with a camel's-hair brush in a very dilute state, and the operation repeated to obtain the necessary intensity. After every application the excess of colour should be removed with a sheet of blotting paper. When colouring large surfaces, it is advisable to pass over it a broad brush dipped in plain water before blotting off; this evens the colour. In working up the sky the transparency should be turned upside down, and the colour applied from the landscape, a natural gradation will thus be obtained.

### PERSULPHATE OF AMMONIA.

[Paper read before the Edinburgh Photographic Society.]

PERSULPHATE of ammonia, a white crystalline salt, somewhat deliquescent, and represented by the chemical symbols  $\text{NH}_4\text{SO}_4$ , was introduced to the photographic world a little more than a year ago by Messrs. Lumière, to whom photographers are indebted for so many good things in applied chemistry, and the advantages of its peculiar action were soon recognised—that of dissolving away the denser masses of metallic silver in apparently much greater proportion than it removes the thinner and more superficial layers which form the half-tones and faint details in the shadows, and it is now considered a very necessary addition to the laboratory. More especially, perhaps, is it useful to the inexperienced amateur, whose negatives so frequently partake of the soot-and-whitewash-giving variety. It is in this class of negative, under-exposed and over-developed, that the characteristic action of the persulphate is found most beneficial, as by it the over-dense high lights can be thinned down to any extent required, while the half tones and shadow detail are acted on to a comparatively slight extent, so that harsh contrasts are greatly modified, just the reverse of what would take place when using the ordinary ferriocyanide of potassium and hypo reducer (Howard Farmer's), with which the half-tones and faint superficial details would be cleared off before the high lights were much altered.

The chemical reactions which bring about this apparently paradoxical result do not appear to be as yet thoroughly understood, and considerable discussion is still taking place between the upholders of the various theories in the endeavour to account for what seems to be, at first sight, a selective action of the persulphate on the denser parts of the negative.

The hypothesis put forward by Messrs. Lumière is that the chemical action takes place chiefly in the deeper parts of the film, and the silver dissolved out as a double sulphate of ammonia and silver is again partly reduced to metallic silver on coming in contact with the excess of persulphate in the surrounding solution, which metallic silver is redeposited on the surface of the film, thus keeping up the average density there at the expense of the silver removed from the deeper parts of the film.

The amount redeposited is, however, less than that removed, so that, by prolonging the action of the reducer, the whole of the negative image would be in time obliterated.

This explanation of the action of the persulphate is not considered entirely satisfactory by later observers, and the general opinion among them appears to be that a uniform reduction takes place throughout the film, in direct proportion to the density or mass of the silver molecules in each part of the film—that is to say, that if reduction were continued until, say, a third of the image were removed from the densest high lights, exactly a third of the image would be removed in all other parts of the film.

It occurred to me that, if Messrs. Lumière's theory were correct, a negative made by exposing the plate in the camera with the glass side to the lens, ought, on being treated with the persulphate, to have the same appearance as an ordinary negative treated with Farmer's reducer—that is to say, the half-tones and shadow details, now lying in the deeper parts of the gelatine film and in contact with the glass, would be the first to disappear, leaving a negative with stronger contrasts than before treatment.

To test this, I exposed two plates on the same subject, one in the usual way, film to lens, the other reversed, glass to lens; they were exposed for the same time, and developed together, development being adapted to give extreme density in the high lights. They were then reduced together with persulphate of ammonia, and the result, which I pass round, was that both negatives were of much the same character, with no special loss of thin detail in either. This proves, at least, that the persulphate has the same action on the silver image, irrespective of its position in the

gelatine film, and bears out the opinion of recent observers, that the action is more of the nature of a reduction of the amount of development, and is uniform throughout the film in proportion to the deposit of silver. This opinion is also supported by the result of photometric measurements.

Now as to the practical application of the reducer. If the negative has been dried, it should be soaked in water for at least half an hour to soften the film.

I find that the most workable strength for the solution in which the negative is to be immersed is about three per cent., say 15 grains to each ounce of water. It dissolves easily, and, as it appears to be unstable in solution, it should be freshly dissolved shortly before use.

When the desired effect is produced, the action can be stopped at once by immersing the negative for a minute or two, after a slight wash under the tap, in a ten per cent. solution of sulphite of soda. The plate should then be well washed and dried. The silver image acquires a slight pinkish hue, which becomes deeper if left too long in the sulphite of soda solution.

Ammonium persulphate, although a powerful solvent of metallic silver, has no chemical effect on silver bromide. Advantage can be taken of this property to make reversed negatives by contact direct from the original negative, and also to make positives instead of negatives direct from the camera exposure.

To make a reversed negative by contact from the original negative, the process is roughly as follows: The exposure having been made in a printing frame, as for a lantern slide, the plate is developed in the usual way; but, instead of being put into the fixing bath, it is placed in a strong solution of persulphate, from six per cent. to ten per cent., by which the positive silver image is dissolved out of the film. The bromide of silver remaining can now, after a short exposure to light, be developed, and forms, of course, a negative image. To make a positive direct from an exposure in the camera, the procedure is the same, the negative image in this case being first removed, and the positive which is left being developed and fixed.

I made several attempts to produce a reversed negative by this process, but without much success. They all turned out very flat and foggy affairs. It seems very difficult to get rid of a residuum of reduced silver; but, bad as they are, I pass round the best of them, to show that the process is practicable, if not very practical.

I hope I have made it clear that persulphate of ammonia has put a new power into the hands of photographers. The golden rule, to expose for the shadows and let the high lights take care of themselves, can now be carried out to the utmost limit without misgiving.

A whitewashed cottage in full sunlight, framed in dense foliage, need not be passed by, development may be pushed to any extent to secure detail in an under-exposed foreground, and printable clouds can be recovered from the densest sky.

In portraiture, likewise, the modelling of features lost in density can be reclaimed, and the folds of a white dress will reappear. Old negatives, put aside as hopelessly hard, will now again see the light, and will be transformed by this wonder-working reducer into satisfactory printers.

DR. H. SCOTT LAUDER.

### A LAZY-TONGS SHUTTER.

SOME few years past I constructed a shutter in which the peculiar action of the "lazy tongs" or compound lever was availed of, and, as a description of this shutter may be interesting, I offer it for the consideration of those who are looking for a shutter on the "slot before the plate" principle which will act quickly and easily. No other contrivance I know of is capable of so quickly and easily passing a slot across the plate. I assume that this action of the lazy tongs is well understood, so that, bearing in mind that the two short ends of the primary levers have only a short distance to travel in order to carry the terminal end a very much greater distance, and as the opening or closing of this short end can be done in the mere closing of finger and thumb, while the terminal end may have travelled some six or eight inches, the speed of the slot across the plate becomes evident, but, if instead of imparting the primary motion by thumb and finger a spring be used, the speed is greatly increased.

In applying this lazy tongs I make two systems of levers, each attached to a flexible screen in front of the plate, and with a slot—adjustable—between the two. One of the systems—that on the side the slot is to start travelling from across the plate is in its closed-up condition, the other system, that in the part of the screen covering the plate, being in its open or extended condition, it is evident that on opening the short ends of the levers on the closed system the slot will be projected across the plate, and the extended system closed up, or this action might have been reversed, the extended system closed by pressing together the short ends of the initial levers.

During the closing or extending of these systems of levers, the blind itself is wound or unwound on a receiving roller, actuated by the same initial opening or closing of the primary short levers.

J. V. ROBINSON.

## TWO NEW POINTS IN COPYRIGHT LAW.

In the case of *Baschet v. the London Illustrated Standard Company, Limited*, and others, which was heard by Mr. Justice Kekewich on November 8, counsel for the defendants raised two points of interest, at least one of which, it was stated, had never been the subject of judicial opinion.

The action was to recover penalties and damages for the infringement by the defendants of the plaintiff's copyright in five photographs which had been duly registered in France (the country of origin), and in respect of which he was therefore, under the Berne Convention, entitled also to copyright in this country.

The liability of the *Standard Company*, who were the publishers of the paper containing the unauthorised copies, in both penalties and damages was not disputed; but it was urged on behalf of the printers, who were stated to have acted innocently, that they were not liable to penalties, as they were merely the agents or servants of the publishers, and only printed what was sent them to print. Section 6 of the Act of 1862, it was pointed out, subjected to penalties any person who should, without the consent of the proprietor, "cause or procure" any copyright work to be repeated, copied, or otherwise multiplied for sale; and it was urged that, upon the true construction of these words, the person causing or procuring the copies to be made was the only person liable, and that his agents or servants, by whom they were actually made, were exempt.

But the Judge held that the argument failed. The printers, he said, were liable to penalties under the earlier words of the same Section as having, in fact, themselves repeated, copied, or otherwise multiplied for sale copies of the plaintiff's copyright photographs without his consent; and he pointed out that this part of the Section did not require proof of guilty knowledge, although such proof was necessary before similar penalties could be inflicted upon importers, sellers, or distributors.

The second point arose on the construction of sub-section 3 of Section 2 of the International Copyright Act (1886), which was passed to enable the draft Convention agreed to at Berne the previous year to be carried into effect. That sub-section provides that the International Copyright Acts, 1844 to 1886, and any Order in Council thereunder shall not confer on any person "any greater right" or longer term of copyright in any work than that enjoyed in the country of origin. Under the English law infringers are liable to, amongst other things, a penalty not exceeding 10% in respect of every unauthorised copy; and it has been held that, where the infringement has been proved, a penalty must be inflicted in respect of each such copy, and not merely a lump sum in respect of the whole matter. But evidence was given that, according to French law, the penalty for infringement ranged from 25 to 2000 francs in respect of each photograph, however many counterfeit copies might have been made, and it was urged that the plaintiff, not having "any greater right" in this country than he had in France, was not entitled to recover judgement here for greater penalties than he would have obtained in France. As it was admitted that 100,000 copies in all had been made of the plaintiff's five photographs, the difference in the maximum penalties was that between 1,000,000% here and 10,000 francs (say 400%) in France.

But again the defendant's contention failed. The Judge ruled that the words referred to related only to the nature and extent of the copyright and not at all to the remedies for its infringement. He thought it would be absurd to suppose there were no remedies for infringements anywhere other than the equivalents of those in force in the country of origin. It was impossible to work two systems of jurisprudence together in that way; the municipal laws and procedure of the two countries were entirely different. The plaintiff, having proved his case, was entitled to judgment according to the English law for penalties, damages, an injunction and costs.

## CLOUD PHOTOGRAPHY.

At a meeting of the Leeds Camera Club, on Wednesday evening, November 8, "Clouds and Cloud Photography" was the subject of a lecture by Mr. T. Morley Brook, the President of the Manchester Amateur Photographic Society.

The lecturer drew attention to the fact that all painters of eminence recognised the sky as one of the most important parts of their picture, a very material aid to the composition, and one which, if neglected or badly represented, would spoil the harmony of the whole. Not only was this true in painting, but even more so in photographic work, and there were few, if any, landscapes or seascapes which would not be improved by the addition of clouds. It did not always follow that, even if they succeeded in getting a cloud on the same negative as their foreground, it was suitable or in harmony, for the lighting must be suitable to the subject as well as the shape of the clouds to the composition. Beginners and photographers generally found this one of their great difficulties. It was a process which needed care, patience, and perseverance, but, when it was obtained, the difference between the so-called bald-headed print and the one with a properly printed cloud was remarkable.

Mr. Morley Brook dealt with the action of the light on the negative, showing why clouds could not very often be obtained on the same plate, and showed, when really it was desirable, how the difficulties might be

overcome by shielding back the light from that part coming from the sky. The next remedy, and generally the best, was to block out the sky *in toto*, and from another cloud negative print in one suitable. He strongly advised the members to lay in a good selection of cloud negatives, lighted from each side as well as from the back, sunrise, and sunset effects, and not to depend on one bought cloud negative for every picture.

The plate to use and the methods of development were dealt with, and he showed that, while ordinary plates might do for many subjects, yet for those in which colour predominated an isochromatic plate with a pale yellow screen was the best. It was wrong to tilt the camera upwards; let it be horizontal, obtaining a small part of the foreground, which should be focussed sharp in the distance. Development should be weak in pyro, or whatever reducing agent was used. Softness and delicacy, rather than harshness, should be aimed at, not only from the point of ease in subsequent printing, but also from that of pictorial effect. Following on to the actual printing, both for silver, platinotype, and bromide work, many useful hints and dodges were explained, the result of much experience and careful study.

In conclusion, the lecturer recommended his audience to never lose the opportunity of acquiring a good cloud, for, if they were in earnest, and meant to do anything better than "the usual thing," they would at some time or other find a good use for such effects.

A series of photographs, both direct and enlarged, illustrating the lecture, was passed round for inspection, the striking differences and the beauties of the finished work, as seen with its cloud effect, as against the bare print with its white sky, being very much appreciated.

## ON SHUTTERS.

[From the *Photo-Gazette*.]

The perfect shutter should combine certain qualities which many photographers do not even trouble themselves to study. Its principal quality is not so much, as many believe, its rapidity as the way in which the exposure is distributed. It might be supposed that, if the lens is quickly uncovered and quickly closed, the conditions which constitute a good instrument are fulfilled. But this is a hypothetical state of things, and the efficiency of the shutter is a practical question. The ideal shutter permits the lens to be fully uncovered during the entire exposure, and occupies no time at all in opening and closing, a utopian condition of things which is incapable of realisation in practice. Before discussing whether it is a condition of things to which we can approximate, it may be well to notice the different systems of constructing shutters in vogue in commerce. These may be divided into two classes: (1) shutters placed close to the lens (we shall see later which is the best position in this case); (2) shutters placed directly in front of the plate.

Shutters of the first class can be subdivided thus:—

- A. Shutters with circular movement.
- B. Shutters with glass.

In shutters having a circular movement it is necessary to distinguish between the lateral aperture and the circular aperture. The lateral aperture is arranged in an opaque disc, which rotates around an axis; if this point of rotation is at an infinite distance from the aperture, the drop-shutter pattern is the result. This pattern can be made by a board falling by its own weight, or accelerated by a spring, or by a roll of opaque material unwound from one roller and wound on to another, a form which can be made very compactly.

Whatever may be the arrangement, however, the opening should be of rectangular form, with its greatest dimensions in the line of fall. A square opening, with its side equal to the diameter of the opening, gives an exceedingly low efficiency. The time of exposure may be divided into three parts: (1) Poor image formed at the commencement of exposure by the edges only of the lens; (2) good image, during full aperture; (3) poor image, from this second point up to the end of the exposure, the image being again formed by the edges of the lens. Now, if the square is of the size of the opening, it is evident that the second exposure would be much too short in relation to the sum of the other two. On the other hand, by making the aperture oblong, the period of full aperture is prolonged. The drop-shutter form is one of the best and simplest yet designed.

When exposure is obtained by means of a plate bearing an aperture and pivoted on an axis, this opening ought to assume a sector form in order to equalise the time of exposure over the whole opening, and for the reason stated above it is necessary that the two radii bounding the sector be separated by a distance greater than the diameter of the opening to be uncovered.

The central opening is obtained by several plates moving in opposite directions, either pivoted around an axis or attached to two shutters moving in contrary directions; or, lastly, by a movement after the manner of the iris diaphragm. By these devices the centre of the objective is uncovered first and remains open longer than the edges. In the most perfect forms of shutter a special adjustment is provided whereby to considerably increase the time during which the shutter is completely open in relation to the time occupied in opening and closing.

B. Flap shutters are especially used for landscape and portrait work, since it is possible to give the foreground a longer exposure than the sky, and to thus obtain clouds and landscape on the same plate. This is a very positive advantage, but shutters of this class cannot compare with those of circular movement in point of rapidity.

The best place for a shutter depends on what it has to do; it may go immediately in front or behind the plate, or close to the diaphragm between the lenses; but its position is not to be chosen without reason. A "drop" pattern shutter may be placed anywhere, but a shutter, opening and closing from the centre, must be placed close to the diaphragm. Were it placed in front or behind the lens, the centre of the plate would receive much more light than the edges, and the defect, already very common amongst objectives, would thus be increased, whilst, if placed against the diaphragm, and preferably just behind it, the gradual access to and removal from the plate of the light is uniform.

The centre of the lens is the most suitable place in all cases when very short exposure is to be made, since, the space to be covered and uncovered being smaller, the movements can be made more rapidly. While the occasions on which extreme rapidity is necessary are rare, shutters which can be depended upon to give it are rarer still, and for such high speeds an anastigmat of the best make is necessary. In view of the fact that the best anastigmats are most delicately mounted, and that few firms, except lens-makers, can be trusted to exactly center a lens on a shutter, it seems best, for special subjects, to retain the mounting of the lens, and to place the shutter either in front of or behind the lens. By placing it behind, there is the advantage of one shutter serving several lenses. As a general rule, it will be found best to keep the lens intact, and to use a drop shutter of some form either in front or behind the lens. This will answer all ordinary purposes, such as landscapes, portraits, street scenes, and others where no higher rapidity than  $\frac{1}{100}$  of a second is required. In special cases,  $\frac{1}{100}$  to  $\frac{1}{1000}$  of a second, the use of a shutter opening and closing from the centre is necessary, and, as this is generally used for serious work, the element of price is of secondary importance. There is still to be mentioned the glass shutter, which uncovers the lower part of the lens first, gradually rising and falling back, a form the special quality of which recommends it for landscape work, owing to its giving more exposure to foreground than to sky.

Shutters placed directly in front of the sensitive plate are of great speed, giving exposures down to  $\frac{1}{1000}$  of a second. They are usually made with a blind carrying a slit which, in its passage across the plate, successively exposes horizontal sections. The objection to this form of a shutter, that all the parts of the image are not obtained at the same instant, is purely theoretical, for the speed of the shutter is much greater than that of the object.

It will have been seen from the above that the best shutter does not exist. None is absolutely best, for each in its place has advantages over others.

For the greatest speeds, the focal plane or diaphragmatic shutters; for less rapid exposures (animals or portraits in the studio), a shutter preferably fixed behind the lens; for general work, where equality of illumination is required rather than great rapidity, a drop shutter.

COMTE D'ASSCHE.

#### PHOTOGRAPHY FOR ARTISTS.

ARTISTS are usually great abusers of photography; they do not, as a rule, consider it an art, but as a poor mechanical process, giving, not a picture, but a dead-alive representation of an object. "A portrait done by means of photography," I heard an artist say some short time since, "does not truthfully represent the sitter. It appears as though it was carved in stone, and there is not an animated expression about it to show that it was alive. If there is a smile, it is a set 'plaster of Paris' one."

This I do not think is correct. I consider that a photograph is an exact reproduction of the expression and pose of the sitter (providing too short a focus lens is not used). The lights and shades may be slightly exaggerated, as the plate has yet to be invented that will allow of a correct exposure being given the shadows without over-exposing the high lights. A painting cannot possibly correctly reproduce the expression of a person's face, no matter how clever the artist, as it must be constantly changing during the tedious sittings.

I do not wish to discuss whether photography is an art, for it has been thoroughly thrashed out before. Certain it is, many pictures have been made—as the walls of the Salon and Royal Photographic Society will testify—that could not be equalled by many artists of repute.

Photography is a very great aid to an artist, whether he be a "pot-boiler" or a Royal Academician. It enables him to make a thorough study of the different phases of any one subject. Suppose, for instance, one came across some beautifully lighted clouds: a snap-shot could be taken of these at the instant the best effect was seen, before it had time to change. In sketching them they would have considerably altered before the sketch was complete, and the beautiful delicate lights and shades lost. Clouds in a landscape are very often the making of the picture; and all kinds of clouds—stormy, sunset, and sunny—could easily be studied by means of a snap-shot camera. Again, many an idea for figure studies can be picked up in the streets by aid of a camera.

In studying animals no doubt the camera will be of the greatest use, as they are very hard to paint on account of their ever-changing attitudes. By photography being of use to the artist, I do not mean that they should take the photographs and then copy them in colours. There would be no art in this. What I mean is, that the photographs are to give ideas and catch expressions which it would be impossible to do by means of sketching. Perhaps out of each photograph there would not be more than a quarter of an inch square that could be utilised, but it would all help.

The perspective of photography is not the same as the artist's. No matter how long the focus of the lens is, the foreground will be larger, and the distance smaller, than an artist would paint them. Sometimes it is possible to come across a view that has a very picturesque composition, but contains several blemishes—such as a tree or other part—that would form a more pleasing picture if removed. If this view was photographed, it would be of great use, as the artist could remove all ugly parts, and introduce figures or other objects to render it more artistic.

For artists whose speciality is painting war scenes, photographs taken on the battlefield would considerably aid them in getting the pictures true, as they would correctly reproduce the scenery, the positions of the men, and, above all, the different expressions of the wounded and dying. Paintings of battle scenes have mostly to be imagined rather than painted from the actual scene, for it would be very risky setting up a canvas and painting during the excitement and din.

Photography, perhaps, is the most useful in assisting that class of artist known as the "pot-boiler." It enables him, after he has drawn in the outline of the portrait or view, to paint in the detail without troubling the sitter to stay any longer, or sitting out in the cold or heat to paint the view from nature. The result will contain more detail, and will be quite as good, if not better, than it would had it been painted straight away without the assistance of a photograph.

Some artists will not use a photograph to paint from at all, as they have the idea that it will spoil their originality, and make them rely on other persons' work, instead of working out ideas for themselves.

An artist usually composes a picture from several sketches. Why should he not make it from several photographs? They would supply a lot more detail than sketches, and would be easier and more rapidly executed. If the artist is a specialist in any particular kind of work—architecture or marine, for instance—photography would greatly assist him in their study. If he came across a yacht or brig, the build of which he greatly admired, what would be easier than to take a snap-shot of it?

Artists will also find the camera useful in recording the types of different races they meet with when travelling abroad.

If artists only recognised the usefulness of photography, we should see them all in possession of a camera.

OSBOEN THORNBERRY.

#### THE ECONOMICS OF PHOTOGRAPHIC PRICES.

THE term economic in its ordinary meaning is not strictly applicable to the selling price of photographs and works of art generally, inasmuch as the market value of these articles depends largely on considerations to which it is impossible to assign any stable money value; at the same time, there is also a proper economy of those qualities which fix the price between good and bad photographs, and with these I shall attempt to deal.

The foundation principle of the economics of trading is that there cannot be, in one market, two prices for the same article, this being what is called the law of "level prices." On the slightest acquaintance with the photographic market, we find existing, side by side, many different prices for work which is to all appearances the same; this state manifestly contradicting the first rule of all trading. The contradiction is only apparent, for, if the articles were identical to the purchaser, then, according to the law of level prices, competition must bring down the rate of the dearer. The drop does not occur, since we are aware that in every town are photographers who continue to command high prices, oftentimes double the rate of others in the town with whom they are competing, and, obviously, the high prices could not be maintained if the articles sold were all of equal value in the public mind. In spite, then, of the fact that one cabinet in size and material is very much like another, level prices do not obtain in photography; but, on the contrary, a scale of charges from high to low. We may deduce from this that it cannot be competition which decides the price of photographs, but some special property residing in the works of the individual photographer.

In general trade this individuality is not very marked, and prices come to a level because they are determined by competition and cost of production—i.e., wages, material. In photography, other factors come in. Certainly the price of work is regulated to an extent by cost of production, though not to a great amount. In this respect photography is like art. We must allow that a "pot-boiler" requires as much paint, canvas, and labour to produce as the work of a master, yet the one sells for 5*l.* and the other for 500*l.* So with the photograph: plainly indicating that cost of production does not settle the price.

Competition, again, is the main power in determining the price of things which every one can be taught to produce, such as hand

cameras, drop shutters, dark-room lamps, the value of these being decided by the number existing, with the cost in time and material to produce them. When, however, we come to the making of a good photograph which many cannot be taught to do, and only a comparatively few can do with success, the price is of necessity regulated by the number of capable men, and the amount they produce. Thus, when only a few men have sufficient skill to make a certain class of photograph, these few may fix the price in a quite arbitrary manner. Competition and cost of production, need not enter largely, if at all, into their operations.

The conclusion we are driven to accept is that the value of every photograph is not controlled either by cost of production or competition amongst the producers, but by some more remote and elusive feature. We all know a superior from an inferior photograph, and though easily distinguished, it is not a simple matter to analyse and lay down in what consists those superior qualities, which even the public recognise, since they readily pay high prices for photographs which possess them. It may be accepted without doubt that the higher the quality of work the larger the price it will command, hence a complete analysis of the quality of a photograph will reveal the secret of its worth.

The merits of a photograph are decided by its technical excellence, æsthetic qualities, and artistic conception.

The Technical excellence is perhaps fifty per cent. in settling the selling price of the photograph, because slovenly and careless manipulation detracts from the worth of manufactures of every kind. The importance of good technique is somewhat overlooked by the rising photographic generation, and it is not striven after with that persistency characteristic of an earlier time. This arises partly from a conviction that artistic and æsthetic qualities take a higher place than mere mechanical work, and partly from the lack of assistants capable of doing what is required. With regard to the latter, the professional man cannot secure assistants of ability merely for the asking, nor by offering a large wage: for they must first be trained.

Photographers make the grave mistake of regarding the training of assistants as outside their province, whereas it is solely an employer's question, because it is so intimately related to prices, and consequently profits. Employers also pay too little attention to the social status of those they select as apprentices and assistants. To make a good photographer, a lad must come from a station above the working classes, for undoubtedly the middle and upper classes supply the best photographers. In my opinion, prices will not reach the high-water mark until both employer and employed are drawn from the cultured.

Good technique being assured, the æsthetic qualities affect the money value of the work. These it will be sufficient for me to enumerate, without entering into any discussion of their nature or the reason of their value. The premier position must be given to the style, that stamp which makes a man's work stand out from that around him, and yet is in such good taste as not to constitute eccentricity. The work of all photographers who have made a reputation and commercial success is marked in this way so plainly that their unnamed productions may be picked out from amongst a selection of other workers.

Allied to this feature of style is that of originality, a trait that must exist in all good work. It should not be overdone, and be skillfully employed to suit the public taste, yet, without some trace of originality, it is scarcely possible to command the highest prices.

Lastly, there is distinction. A photograph may possess style and originality, and, at the same time, be a failure for want of any signs of superiority, lacking that air of distinction which gives to the best productions the character of being things apart, unique and rare.

Next to style, originality, and distinction, come the purely artistic qualities which enter as factors in determining price. The arrangement of every photograph must observe those rules of composition, balance, proportion and lighting recognised by the general intelligence of artists as constituting the laws of art—these in practice meaning that the work shall not offend against good taste, the sense of beauty, the knowledge of true form acquired by persons of average culture. To specify or illustrate these rules of art is not my purpose; sufficient for me to indicate them as influences that control the money values in the photographic market.

Besides the technical, æsthetic, and artistic merits that increase the value of a work, there are also several outside factors which have a pronounced effect on prices. The foremost of these is fashion. To obtain the attention of the fashionable world will alone give a high value to work which, when the craze is past, falls back to its normal place. So powerful is the support of fashion that it may safely be said the man who succeeds in attracting it, and properly manipulating the market he has thus created, may raise his prices to a height that puts all questions of competition and the laws of markets entirely on one side.

Connected with the voice of fashion is the consideration of the photograph as a luxury. Any picture, great or small, to command a fancy price, a luxurious price, must be a luxury, having a rich and valuable appearance, a look of wealth, of richness—a thing it is a pleasure to possess. Photographs of this nature can never be cheap, nor common; never be made for the multitude; but must remain as luxuries, and be purchased at high rates.

To recapitulate, it has been advanced that photographic prices are not finally adjusted by competition nor cost of production, but by the skill,

the æsthetic and artistic merits displayed in the photographs; their more or less luxurious appearance, and the trend of fashion also having great influence. It follows from these conclusions that there is scarcely a limit to the price that might be paid for a photograph, because there is no limit to the possible æsthetic and artistic qualities it may display; no finality to the power of fashion, and the price its votaries would pay for a luxury. Even to the ordinary purchaser one excellent work at a guinea is valued more than any number of indifferent ones at 1s. or 2s. each; and this fact alone indicates that quality is the real measure of photographic value.

Quality being what fixes the price of work, it is evident that, when employers are wanting in culture, and assistants without skill, prices will be low, and as these become greater in each class, so prices will have a tendency to rise with the increasing luxuriousness of their productions. The settlement of prices is thus largely in the photographer's own hands, and he is not to any vital extent a victim of competition nor of circumstances over which he has no control. When prices show a tendency to fall, the only remedy is to improve the quality of work, on the technical, æsthetic, and artistic sides, and recent events amongst professionals could be brought forward to support this contention.

Finally, it must be recognised that, if work is entirely lacking in all the above æsthetic and artistic qualities, does not appeal to fashion, and is utilitarian and not luxurious, its price will be fixed by the ordinary market laws of competition and cost of production. A large proportion of photographic work is of this description, and, of necessity, its price is beyond the control of the producer. He must accept the usual market rate for his wares, or give place to a rival. He possesses but little voice in the matter, for the purchaser has the main control. In such cases the remedy is combination amongst the producers against the purchaser, the former agreeing not to supply the latter below a rate much above the competition level. Combinations, however, are generally too weak to stand the strain of the fierce competition of modern markets.

JOHN A. RANDALL.

#### LARGE NICOL PRISMS.

MR. C. D. AHRENS gives in *Nature* the following particulars of some of the larger Nicol prisms which he has made from blocks of Iceland spar within the last thirty years:—

"(1) In 1873 Dr. Spottiswoode bought a very fine block of spar from Mr. Tulinus, of Copenhagen, who then owned and worked the spar quarry at Eskiförðr in Iceland. Out of this, which was absolutely flawless, I made a Nicol prism having a clear field of  $3\frac{3}{4}$  inches diameter, the length of each side being 12 inches.

"(2) In 1874 I made a second prism from the same block of spar just mentioned, and also a third from another piece of spar bought by Dr. Spottiswoode. Both of these prisms had a clear field of  $3\frac{1}{2}$  inches, the length of the sides being  $11\frac{1}{2}$  inches. These are now at the Royal Institution.

"(3) In 1875 I made a Nicol prism for Mr. Frank Crisp, of  $3\frac{1}{2}$  inches field and  $11\frac{1}{2}$  inches in length, which he used in a polariscope in conjunction with the first one mentioned above, which he had acquired from Dr. Spottiswoode. These Mr. Crisp sold, and are now in England.

"(4) In 1876 I made two more large prisms for Dr. Spottiswoode, one of 3-inch and the other of  $2\frac{1}{2}$ -inch field, as spar was even then beginning to get scarce. These are now at the Royal Institution.

"In all these prisms the end faces were the natural crystal faces, only smoothed and polished, and the plane of section made an angle of  $87^{\circ} 30'$  with them, or  $21^{\circ} 30'$  with the length-axis of the prism.

"In none of them was Canada balsam used as the cement (I have not used it for this purpose for thirty years past), but a special material."

#### A NEW AMERICAN CAMERA COMBINATION.

ACCORDING to the *Rochester Union and Advertiser*, within a few weeks all the large camera manufacturers in Rochester, N.Y., will be united in one company, with a capital of \$3,500,000. Options on all of the plants in the city have been obtained, and experts are now at work examining the books of the various concerns.

Rochester stands at the head of the list as a camera-manufacturing city. All during the hard times, when other industries were suffering more or less and hardly any branch of manufactory was profitable, the camera companies of this city were working full time and making money. The industry is one of the most important in the city, employing many thousands of hands, and circulating weekly thousands upon thousands of dollars. The combination of the various manufactories will greatly decrease the cost of manufacture and marketing, while not decreasing the number of hands employed or the amount of money paid out in wages. It is in every way desirable, and when consummated will greatly enhance the city's mercantile and manufacturing reputation.

The officers of the new company will be made up from the officers of the concerns that are taken into the consolidation, and the board of directors will contain the names of some of the most prominent capitalists of the city, who will be active in its management.

# PHOTOGRAPHY IN NATURAL COLOURS—MR. FRIESE-GREENE'S SYSTEM.

MR. FRIESE-GREENE has patented some improvements in taking and in projecting photographic images, in means therefor, and in photographic negatives, the primary object of which is to produce photographic negatives containing vibrations of the various colours existing in the original scene or picture (in other words, negatives containing these various colours in a latent state), and to reproduce the scene or picture from the negative upon a screen or the like in the natural colours.

We append the patentee's description, taken from his complete specification:—

"A photographic negative of a scene or picture is taken by means of a

camera or photographic apparatus through a transparent material or medium bearing three or more primary colours. The negatives thus obtained will contain vibrations, not only of the several colours employed, but also of all the varieties of colour caused by the blending of these colours. Then by obtaining a transparency in the usual way from this negative, and projecting the image from the transparency upon a screen by means of a magic lantern or projecting apparatus through a transparent medium coloured and constituted similarly to the transparent medium employed in taking the negative, the image appearing on the screen will show all the colours of the original scene or picture. The invention allows of taking and of projecting animated or changing scenes, as well as scenes of stationary objects.

"The transparent medium which I prefer to employ consists of a disc

Fig. 2

of glass or suitable material composed of differently coloured sectors. In taking a photographic negative, or in projecting a transparency obtained from such negative, this disc is caused to revolve rapidly in front of or behind the ordinary lens of the taking or projecting apparatus, or between the lenses when more than one lens is employed, the several coloured parts of the disc moving successively past the lens during one and the same exposure.

"I may also employ, instead of the revolving disc, a band or strip of suitable transparent material bearing the three or more primary colours in regular repeated succession, caused to travel rapidly in front of or behind the lens; or I may construct the coloured disc above referred to in the form of a lens composed of differently coloured lens sectors having a common focus. In this last case, the lens is used alone and in place of the ordinary taking or projecting lens.

"By these means I obtain a single negative or transparency instead of the three negatives or transparencies hitherto required in colour photography.

"In Figs. 1 and 2 the photographic camera shown is constructed in substantially the usual manner, and comprises the objective piece 1, front 2, bellows 3, rear part 4, and back 5, mounted on the base 6. 7 is the objective, consisting in this arrangement of an ordinary lens. A horizontal axle 8 carried in a bearing bracket 9, fixed to the camera front 2, extends through the latter into the interior of the camera, where

Fig. 4

Fig. 3

it is provided with a rotary disc 10, constructed as hereinafter described, and arranged to be rotated rapidly behind the objective. The rotary motion can be imparted to the disc 10 in any suitable manner. In the particular arrangement shown there is fixed upon the outer end of the axle 8 a small cord pulley 11, which is driven by means of a cord 12 from a considerably larger cord pulley 13, rotated by hand by means of the handle 14. The pulley 13 is carried by a projecting part 15 fixed to the camera front 2. The aforesaid disc 10, which is shown more fully in Figs. 3 and 4, consists of a rubber ring 11, formed with three radial strips 12 and a central boss 13, and which is adapted to be clamped fluid-tight between two circular plates 14, 14 of colourless glass or other transparent material by means of two peripheral flanges 15, 15, through which pass a number of tightening screws 16. A fluid-tight joint at the boss 13 of the rubber ring is further ensured by means of two plates 17, 17, which are clamped against the outsides of the glass plates 14, 14 by means of a nut 18 screwing on a hollow bolt 19 formed with a head 11. Rotary motion is imparted from the cord pulley 11 through the axle 8 by keying the bolt head 11 on the axle 8. The bolt head 11 is preferably formed as a cord pulley as shown, so that when it is desired to arrange the disc 10 in front of the objective, the said disc can be driven directly from the cord pulley 13 by means of the cord 12 passing around the grooved bolt head 11.

"The space comprised between the ring 11, its boss 13, and the glass

Fig. 6

Fig. 5

plates 14, 14 is divided by the three radial strips 12 into three compartments of sector shape, which are filled respectively with liquids of separate colours, preferably blue, green, and red, but other colours may be adopted, as, for example, blue, red, and yellow. Each compartment can be filled through a hole normally closed by a plug 20, the air displaced by the liquid escaping through a hole normally closed by a

plug 21. The actinic effect of the exposure of the colours can be varied by varying the intensities of the colours.

"Instead of making the three sectors containing the three differently coloured liquids of equal area, and varying the actinic effect of the exposure of the colours by varying their intensities, I may employ liquids of uniform intensity of colour, and vary the exposure by varying the areas of the sectors. In such case the green sector should have about half the area of the red sector, and the blue sector be very much smaller than the green. The proportions will depend to some extent upon the particular kind of sensitive film employed, but they will be chiefly regulated according to the length of exposure required for photographing the several colours, an important point being that all the colours shall have

an equivalent amount of exposure, having regard to the fact that blue requires much less exposure than green, and green less exposure than red.

"Also instead of employing the disc 10 containing the liquids as above described, I may employ the disc 10<sup>a</sup>, shown in figs. 5 and 6. This disc is composed of three differently coloured sectors of single thicknesses of glass or other transparent material fitted in a peripheral ring or bezel 15<sup>a</sup>, and clamped between two plates 17<sup>a</sup>, 17<sup>a</sup>, and fixed upon the axle 8 in the manner above described with reference to the disc 10. In this arrangement the sectors are made of different areas corresponding to the requisite exposures of the respective colours.

"In taking a photograph, the disc 10 (or the disc 10<sup>a</sup>, as the case may

be), is caused to revolve rapidly by turning the handle 14, so that the several coloured parts of the disc will pass successively behind the objective 7 during one and the same exposure.

"In projecting the image upon a screen the transparency 22, obtained from the negative (see fig. 7) of the photograph taken by means of the apparatus hereinbefore described, is projected through the lens 23 of a magic lantern 24, in which a disc 10, composed of sectors similarly coloured to those of the disc 10 used in taking the photograph, is revolved rapidly in front of the lens 23. The picture appearing on the screen will show all the colours of the original scene or picture.

"The disc 10 can be rotated by any suitable arrangement; in the arrangement shown it is mounted on a horizontal axle 25, supported

laterally of the lens piece 26 in a bracket 27. Rapid rotary motion is imparted to the disc 10 by means of a cord 28 passing around a small cord pulley 29, keyed on the axle 25, and around a large cord pulley 30, carried by a bracket 31, and provided with an operating handle 32.

"The coloured disc 10<sup>a</sup>, shown in figs. 5 and 6, may also be constructed as a lens, by dispensing with the central attachments, and the sectors being curved to a common centre. This lens, which does not rotate, is employed alone in place of the ordinary lens in both the camera or photographic apparatus and the magic lantern or projecting apparatus.

"In figs. 9 and 10, which illustrate this parti-coloured lens, 33 represents the lens; it is composed of three lens sectors having one common centre, arranged in a suitably constructed holder 34. These lens sectors are coloured in separate colours, and the respective sizes of the sectors correspond to their respective colours as hereinbefore explained. The

negative images produced by the several sectors will be, as it were, intermingled with one another to form one single negative image containing vibrations of the several colours. This image, when transferred to a transparency and projected upon a screen by means of an apparatus or lantern having a corresponding parti-coloured lens will reproduce the original scene or picture in its natural colours. For some purposes the lens sectors may have slightly different foci.

"If it is not required that the picture obtained should be coloured, I employ a lens composed of several uncoloured lens sectors having one common centre, and they should be of equal dimensions. The negative obtained bears, as is the case when coloured lens sectors are used, as many pictures as there are sectors, these pictures being, as it were, intermingled or superposed, the result being that the positive picture subsequently produced is softened, and 'retouching' becomes practically unnecessary."

#### CONCERNING LOCAL EXHIBITIONS.

SURELY nothing is more stimulating or educative than the holding of a reasonably representative exhibition of pictorial photography in the provincial centres.

This, at least, is the opinion formed while the glamour and memory of our own recent display is still fresh in the mind.

The stimulating effects have in our case taken many forms. In the first place, members who have hitherto been chiefly remarkable for their technical abilities have been induced to strive, in several instances with much success, to introduce special indications of grace, taste, emphasis, and selection into their prints, and have also been at the pains of learning what is the particular fashionable foible that is likely to tickle the eyes of those "Heavenly Triplets" who do the judging.

Quite an unrelated form of stimulation is the outcome of the demonstration of various processes which an exhibition affords opportunity for. In our own case a particular printing process, which is by no means a novel one, obtained a very considerable number of converts. One, a certain energetic professional, who had not previously used the paper in question, has since been employing it wholesale.

As for the educative influence, this is immense. First, there are the members. Take our own as an average sample of other societies. Out of some hundred and forty or so, I would wager that not a dozen have been to see the Exhibition lately open at the Salon, which, after all, may indicate great sanity. But what is to be said of the fact that not ten per cent. have been to the Royal? "True 'tis, 'tis pity; pity 'tis 'tis true" that three-fourths of our members never knew, until we opened our late Exhibition, that certain teachers in the great world of pictorial photography have discovered that eyes were given to us that we should not see clearly, and fine lenses bestowed upon us that we may avoid definition.

Then, there is the opportunity of reminding Judges, and others whom it may concern, that photography, stripped of her artistic domino and mask, is in many eyes quite as acceptable as when disguised in the brave attire of the painter-man.

*The Birth of a Snow Flower*, by Mrs. Main, is one case in point; *The White Cactus*, transparency, by Mr. Henry Stevens, is another instance; *An Old Oak Cabinet*, by Mr. G. W. Jenkins, is a third. All the foregoing are cited from our late Exhibition, and bear witness that perfect form, gradation, brilliancy, and almost infinite detail are waiting for the clever artist to conjure with.

Above all, such an exhibition teaches the member that *in medio tutissimus ibis*—that is to say, if he wants to make a creditable ap-

pearance on exhibition walls, and also stand well in with the medal winners.

After all, the best educative outcome of a local exhibition is that it teaches the local public that photography is a good deal more than is evidenced by show-case, by process block, or by the callow monstrosities which countless amateurs are constantly bringing out of their breast pockets for the admiration of much-loved acquaintances.

Of course, we of Croydon could not get "all the blood of all the Thomases;" but we managed, as I suppose any other local society might do if it chose, to bring together a sufficiently impressive collection to extort many expressions of admiration and of surprise from casual visitors, a considerable proportion of whom evidently had no idea of the lofty status which photography has of recent years attained. If it does nothing else, a well-arranged local show adds an often much-needed dignity, and lends seriousness to the practice of photography, whether as a vocation or as a recreation.

Nor is it to be forgotten—although this is, no doubt, a small matter—that a local photographic Exhibition is of considerable educative value to local art students and artists.

Some of these scan the prints for facts, others to familiarise themselves with the face of the surrounding country; not a few find amongst the landscape suggestions for subjects. This last is by no means a mere supposition, more than one painter having within the past week or two acknowledged to me their indebtedness to photographic exhibitions for finding the germs of successful painting.

Of course, one cannot have local exhibitions without medals, which are at times run down because, like many other good things, they have sometimes been put to bad uses. Why should the amateur work like a porter or a packhorse, and toil many a league picture hunting? why should he drudge through the long watches of the night, if, when success crowns his labours, he is to be put off with that convenient line from A. A. Proctor, "The striving is the prize?"

Anyhow, amateurs, and professionals too have, most of them, a consuming thirst for medals. And quite right too, for without such a hall mark of merit the exhibitor may, in the words of a Cookney poet, well exclaim, "E don't know where 'e are." I do not mean to infer that he will always be sure of his bearings by examination of the medalled pictures; but, at any rate, the worst marks will not often come to the top. Some people make much needless fun over medal-giving, calling medal-winners 'pot-minters,' and other unkind names. The aforesaid are, I fancy, mainly recruited from those who have tried to win medals and failed, or from those who have such a colossal reputation, all their "very own," that they fear to put it to the test by competing against the forward, pushful crowd. Let these objectors reflect that all artists simply love appreciation, and that they especially dote upon the medal.

Hear what says that great, precocious genius, whose brilliant beginning was cut short by death—I mean Marie Bashkirtseff: "If two years ago I had received an honorary mention, I should have fainted; if last year they (the Paris Salon) had given me a medal, I should have wept with joy."

The main objection to medals is that they entail judgments and, consequently, Judges. This objection raises up an almost interminable series of points to squabble over. First, who is to judge the Judges? How are they to be picked out, and by what sign shall they be known? No completely satisfactory answer is forthcoming. If you value experience of exhibitions and familiarity with most of the exhibition work, then it is only needful to look over the prospectuses of a few local exhibitions to enable a more or less suitable selection to be made. This done, there immediately arises the cry of "hark Judges!" A certain proportion of exhibitors whose work is regularly passed over by either of Messrs. A, B, C, D, E, and F, naturally long for fresh blood, and refuse to submit prints to the aforesaid. As for members, they will probably object to the board of Judges as leaning either too much to the art or too much to the technical side.

Another trouble which accompanies medals is the inducement held out to create classes which often have little or no legitimate *raison-d'être*, and are besides in many ways harmful. Thus, an exhibitor, if he takes, say, half a dozen landscapes under almost identical circumstances, may possibly find that he can indiscriminately enter six prints from the six negatives in as many classes, thus: (1) Landscapes, (2) Enlargements, (3) Hand camera, (4) Excursion, (5) Open, (6) Lantern Slides. Again, the undue multiplication of classes very materially interferes with the effective hanging of a gallery. It is impossible to group exhibits to their mutual advantage and with an eye to the formation of well-balanced arrangements if the collection has to be chopped up into a larger number of variously numerous classes.

No doubt in local exhibitions this lavish creation of classes helps to attract entries, and materially facilitates the bestowal of medals for poor work.

As far as members' classes are concerned, three divisions seem ample for prints, i.e., (i.), the figure; (ii.), other subjects; (iii.), technical and scientific, which last might include a good many intellectual photographers. To the above might well be added an open class for all subjects.

The Champion class is found to be somewhat of a delusion and a snare. A good deal of poor work which has been medalled by very easy-

going Judges, and some few respectable prints, which are "old stagers" as a rule, make up this class.

Naturally, people who have carried off distinguished awards, such as the Royal Photographic Society's medal, &c., do not care a rap about their picture gaining the first place at the Exhibition of the Green-cum-Feeble Photographic Society. On the other hand, they very much object to the bother and expense of packing, to the entry fees, and to the possible ignominy of their print being passed over.

In order to make the open class as attractive as possible, it seems to me that something should be done to get rid of the "hack" Judges. On the other hand, these amiable and, all said and done, generally thoroughly capable, gentlemen are almost a *sine-quâ-non* for judging members' works; for every one knows that the average member generally has his mind stuck full with suspicions of treason, as favouritism; hence he feels that any local man, if appointed Judge, would be biased by what he knows of the exhibitors.

What seems to me a very good compromise is to obtain the "hacks" to judge the members' classes, and elect a well qualified triumvirate of local lights to award the palm in the open classes. By this expedient, outside exhibitors would know that the medal-giving would not be in the nature of a foregone conclusion, as was the case with a certain picture which circulated for some weeks from one exhibition to another as did "the hacks."

The picture is said, under these circumstances, to have been invariably medalled. But one day this remarkable production was switched off into another circuit, in which entirely different sets of Judges ruled, with the result that the medal-winning immediately ceased.

I feel sure that, if this proposal were adopted in many cases, very much larger entries in the open classes would result. Exhibitors, who have been discouraged by the continued passing over of their prints on the part of the hack Judges, would welcome the chance of appealing to an entirely fresh jury of experts, which there are few towns or districts but could provide, especially if a local painter of repute is included, just to remind his photographic *confrères* that correct technique is not the only thing to bear in mind, and that, on the other hand, sham impressionism is not good art.

HECTOR MACLEAN.

#### BIRD PHOTOGRAPHY.

LET me say at once that, beyond photographing very young birds in nests, and some sparrows from my bed-room window with an ordinary camera, I have had no practical experience in bird photography. Therefore, on this account, perhaps, I possess no qualification to offer any words of advice on the subject. But I have had the pleasure of conversing, on several occasions, with one who, for several years past, has spent very many hours in pursuing what undoubtedly must be a peculiarly fascinating branch of photography, namely, Mr. R. B. Lodge, of Enfield, whose work in this direction is well known. And perhaps a few hints, although second-hand, may not be without interest to those who would take up the subject.

In the first place, he who would photograph birds in their haunts should be patience personified, and be able to put up with many inconveniences, such as standing up to your middle for hours in not particularly pleasant-smelling water—employing waders, of course. After spending the best part of a day in this way, you may have the pleasure of seeing your camera or dark slides containing your exposed plates slip into the water. You say nothing, that is if you have been brought up on Y.M.C.A. principles, but, like the parrot, you think a lot. Although you may be dying for a smoke, this is quite out of the question, because it would scare the birds away, and they are what you are endeavouring to photograph. And you mustn't make a noise, for this, naturally, would have a like effect. So you live, for the time, in a state of suspended animation. If you are careful and wait long enough, you may be able to make a few exposures, and, if the light has favoured you, the result may be satisfactory.

By this time it will perhaps be recognised that photographing birds in their haunts is not the easiest of photographic work. The agile little creatures do not allow the operator five minutes in which to focus and expose. Birds as a rule are busy creatures, they have not much time to spare to have their photographs taken, and the operator needs to be alert. The operation of focussing and exposing has to be accomplished almost momentarily, unless the bird be sitting on the nest, in which case it may be disposed to give the photographer an actual "sitting," according him ample time to perform the necessary preliminaries. If the seeker after bird photographs is commercially inclined, and most people are nowadays, he may be able to dispose of the right to reproduce the resultant prints to a magazine editor. Although the photographer may have spent the best part of a week in getting a decent negative, and spent no inconsiderable sum in railway expenses, &c., the said magazine editor may offer half-a-guinea for the use of the photograph. This offer may or may not be accepted. It would depend on the personality of the photographer and the value he put on his work.

Contrary to the opinion of many who could have never used a camera in their lives, bird photographs are not taken with the inevitable Kodak or with an ordinary stand camera, which would depict the birds a microscopical size. Specially designed apparatus is practically essential.

I have seen the various cameras that Mr. Lodge has employed for this work. His first camera and his most recent one possess little in common. Enthusiasm goes a long way, otherwise it would be difficult to explain how Mr. Lodge could tramp miles with the cumbersome and weighty arrangement which did duty when he first commenced this work. Every season his camera underwent some modification. Evolution has been at work, and now this photographer is the fortunate possessor of a camera which seems almost perfect for its purpose. A pony and trap is not necessary to cart it about, which would have been very desirable in the case of his initial camera. He does most work now with an aluminium mounted tele-photo lens fitted to a beautifully compact quarter-plate camera. By means of an eyepiece and a reflex arrangement he can follow the movements of the bird to which he is directing his attention, and, at the physiological moment, make the exposure. The whole is mounted on a piece of willow shaped like a gun stock, to which a single leg to ensure stability is attached. The fastest available plates are invariably used and development carried out with care. For nests an ordinary camera can, of course, be used.

J. A. REID.

### PORTRAITURE BY ARTIFICIAL LIGHT.

The first meeting of the session of the Glasgow Photographic Association was held in the Philosophical Society's Rooms on November 2. Office-bearers for the year were elected as follows:—*President*: Mr. J. Craig Annan.—*Vice-Presidents*: Messrs. J. C. Oliver and Robert Dodd.—*Council*: Messrs. J. E. Hanbidge, J. F. King, William Lang, F.C.S., W. J. McIlwrick, George Mason, A. Lindsay Miller, John Stuart, and Archibald Watson.—*Treasurer*: Mr. George Bell, 152, Sauchiehall-street.—*Secretary*: Mr. Charles Macdonald, 100, West Regent-street.

In the absence of the President, the chair was taken by Mr. John Stuart, the retiring President.

Mr. Stuart made some remarks about the objects of the Association, and urged that the opportunities afforded by it for discussion and mutual assistance should be more taken advantage of. Mr. Stuart then introduced Mr. A. G. Adamson, who addressed the meeting on "Portraiture by Artificial Light."

In the course of his remarks, Mr. Adamson emphasised the leading differences between lighting a figure by daylight and by artificial light. He was of opinion that these differences were so well defined, and, in the case of a reliable and constantly uniform source of light, so easily mastered, that he could never too strongly insist that the hesitation displayed by sections of the profession and amateurs to adopt artificial light, not as a makeshift in the studio, but as a reliable substitute for daylight, arose from fears as to difficulties in manipulation, which were perfectly groundless. The sole secret of success in portraiture by artificial light, as distinguished from daylight, was a very simple one, viz., the use of reflecting screens to a somewhat greater extent than was necessary in the diffused daylight usually used.

Mr. Adamson then went on to speak of the results of his experiments with the various forms of artificial light available. He had found the magnesium light the most valuable actinically, but this light was meantime barred by the impracticability of its proper manipulation. Electric light had been found to be practicable and satisfactory, being easy of control and use, but it involved expensive installation and supply, not always available, and its application was therefore limited. Owing to the scare amongst the insurance companies and their unreasonable attitude towards its use in any form, acetylene was presently almost out of the running. Having considered these, he had cast about for the light capable of universal application, and had turned his attention to ordinary coal gas. Owing to the presence of the yellow pigment in the human skin, the first thing to be done was to get rid of the useless yellow in the gas flame, and the next to devise a plan whereby the necessary quantity of light could be obtained for quick exposure without involving any special gas supply, and he explained how he had devised a coal-gas light so coloured as to be of the same actinic quality as the electric light, and how, having found the practicable light, he had contrived a portable apparatus for supplying it. "As the proof of the puddin' is the preenin' o' it," he then gave a demonstration of the new pressed gaslight apparatus, which his firm have just added to their list of artificial lights for photography. The operations were of a very interesting and successful character, several of the members present sitting to Mr. Adamson, who showed how easily and quickly the effects of light were to be got, and with an average exposure of five seconds produced negatives of bust, half length, and groups of excellent quality, which were developed and handed round for examination, the Chairman stating that these were as fine as he, for himself, should desire. The light carried perfectly over the groups, there being no falling away of brilliancy at the feet.

The lamp itself was very simple and neat, whilst the gas to feed a number of large special burners was obtained without any special supply, by taking out one of the ordinary burners from a gaselier in the centre of the room, and slipping the end of a length of rubber tube over the pipe. This tube led into a reservoir, controlled by a lever and special valve attached to the stand of the apparatus. When the lever was raised, the gas fed into the reservoir, filling it between each exposure, and at the same time keeping alight one of the burners in the reflector for the purpose of arranging the light and focussing. When the exposure was

about to be made, the other burners were lighted by simply turning on the gas to them. The members were very much impressed with the simplicity and effectiveness of the apparatus.

In the course of his demonstration, Mr. Adamson explained that the capacity of the reservoir being one cubic foot, and its being capable of being also used for acetylene gas, which could be manufactured and filled outside the studio, he had hopes of being able to get the insurance companies to modify their position as regards acetylene so as to allow of its being used in the apparatus, seeing that there could be no danger in dealing with so small and isolated a quantity. He also explained how the apparatus took to pieces for easy removal from house to house. The members who were photographed stated that they had not felt the light in any way trying on their eyes. The Chairman, in proposing a vote of thanks to Mr. Adamson for his very interesting demonstration, said that he thought the members would agree with him that this new light of Messrs. Adamson Bros. bore out all he had said, and was bound to have a big future before it, as it certainly had all the qualities claimed for it.

## Our Editorial Table.

### THE GOERZ LENSES: A NEW SERIES.

C. P. Goerz, 4 and 5, Holborn Circus, W.C.

A new series of the Goerz lens (the No. IIa) is being issued, and we here summarise its principal features. The lens is of symmetrical form, each component consisting of five glasses. The largest aperture is  $f/5.5$ , and a non-astigmatic flat field over an angle of  $70^\circ$  to  $75^\circ$  is covered. It is pointed out that each combination, although consisting of five component lenses, has but two free surfaces, and hence it is claimed that the loss of light by reflection is reduced to a minimum.

The single combinations form landscape lenses at the relatively high rapidity of  $f/11$ . They are claimed to be remarkably free from distortion, and are adapted for groups and large portraits. It is recommended that, when a moderate angle only is required, they may be used for architectural subjects with perfect results.

The Goerz anastigmats, Series IIa, are supplied in the following forms: (1) as symmetrical doublets, working at  $f/5.5$ ; (2) as single combinations, working at  $f/11$ ; (3) as sets of single combinations of different foci, forming a "convertible" series of three doublets, varying in rapidity from  $f/5.9$  to  $f/6.3$ .

A four-and-three-quarter-inch lens of the series, covering a quarter-plate, was submitted to us for our examination, the result of which justifies us in confirming the claims made on its behalf. Astigmatism and curvature of field are non-existent, and the lens is of a very high order of optical excellence indeed.

### CATALOGUE RECEIVED.

Newton & Co., 3, Fleet-street, E.C.

THE latest catalogue of Messrs. Newton has been brought down to date by the inclusion of sets of slides on subjects of current interest, such as the Transvaal and the War; Wireless Telegraphy; Birds and Animals, by R. B. Lodge; Spiders, Insects, and Butterflies; Canterbury, the City and Cathedral; China—Burma; Malay Archipelago; National and Tate Gallery; Belgium; Elements of Agriculture—Wheat and Cattle; St. Paul's Cathedral; The Thames; Flower Studies; Australia—Up Country; Meteorology; Astronomical Works in the Solar Physics Observatory; Lang's Fairy Tales; Alice through the Looking Glass; Stations of the Cross from Wood Carvings; Chinese Illustrations of Bible Stories. Attention is drawn to a telegraphic cypher which may be used when ordering any of Messrs. Newton's sets of slides.

### SPECIMENS OF TRADE PRINTING AND ENLARGING.

S. H. Fry, 12, South Villas, Camden-square, N.W.

WE are seldom made the recipients of such charming specimens of printing and enlarging work as those which have reached us this week from Mr. S. H. Fry, who seems, in an incredibly short space of time, to have placed himself in the front rank of his branch of the profession. Mr. Fry specially devotes himself to working for professional photographers, and one of his leading lines is the ever-popular carbon enlargement, while he also undertakes bromide, platinum, and contact surface work in all the pleasing varieties of style and colour which these processes nowadays admit of. Day and electric light are used in his studio, and a staff of expert artists is retained on the premises. It may be said that Mr. Fry is in a position to immediately cope with all the requirements of professional photographers in regard to printing and enlarging.

The specimens submitted to us are of exceptional interest and beauty. First we note a carbon tissue colour chart, consisting of six prints from one negative, in standard brown, warm sepia, portrait brown, red chalk, sea green, and engraving black. Then we have a bromide paper grade chart, the prints being on smooth, rough, "plat-mat," and enamel surfaces, and "Royal" and "C" toned. These two charts are supplied to Mr. Fry's customers for their own use, and photographers, doubtless, find them of considerable service in consulting the tastes of their sitters and patrons.

Contact carbon prints and a 12×10 enlargement from a quarter-plate negative are also before us. The latter is supplied to dealers for advertising purposes at a nominal cost. Some delightfully toned bromide prints complete Mr. Fry's consignment of spec mens.

We can give the quality of Mr. Fry's work the very highest praise. Not merely in the specimens under notice, but in many other prints and enlargements that have recently come before us in the ordinary way, we perceive the influence of a master hand. His long practical experience enables him to get the very best out of negative and printing process, and the perfect command he has over his work should bring him a wide share of support. Mr. Fry, in fact, is one of the best photo printers and enlargers that we have in Britain.

## News and Notes.

**PHOTOGRAPHIC CLUB.**—Wednesday evening, November 22, at eight o'clock, demonstration of the Secco film, by Messrs. Whitney, Graaff, & Co.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Photo-mechanical Meeting, Tuesday, November 21, at 66, Russell-square, at eight p.m. "Architecture and Photography," by Mr. Henry W. Bennett.

At the forthcoming Exhibition of the South London Photographic Society, the following gentlemen have consented to judge the exhibits: Messrs. R. Child Bayley, F.R.P.S., Thomas Bedding, F.R.P.S., and E. J. Wall, F.R.P.S.

THE Hon. Secretary of the Whitehaven Camera Club writes: "I shall be glad if you will note in the next issue of your JOURNAL that the entries for our Exhibition close on November 23, and also that Mr. W. J. Warren, of Leeds, will be the Judge."

MR. W. H. ROGERS, Hon. Secretary, of the Croydon Camera Club, writes: "I shall be obliged if you will kindly note in your next issue that I have changed my address from 106, Holmstead-road, South Norwood, to 46, Bensham Manor-road, Thornton Heath."

THE "Mount" Postal Photographic Club wishes to secure a few more members, to raise number to twenty-five. None but pictorial workers need apply. Send specimens, or references to exhibition awards, to the Hon. Secretary (C. R. Fowler), School House, Wimborne.

THE WAR IN SOUTH AFRICA.—Messrs. Marion & Co., of Soho-square, announce that they will have ready in a few days nine portraits on one card, size of Downey's art studies, of Generals Buller, Symons, White, French, Gatacre, Lyttelton, Walker, Methuen, and Baden-Powell.

**EALING PHOTOGRAPHIC SOCIETY.**—The next meeting of this Society will be held at the Public Buildings, Ealing, W., on Monday, November 20, 1899, at 8.15 p.m. Subject, "Sandell Perfect Films." Demonstration consisting of development, a display of prints and about 100 lantern slides. By Mr. J. T. Sandell.

ON Monday, November 6, the South London Photographic Society had the pleasure of hearing Mr. E. Sanger Shepherd give his interesting lecture on Orthochromatics, which was illustrated by examples of his method of reproduction in natural colours. A highly interested audience greatly appreciated the lecturer's kindness in filling a vacancy at a short notice.

THE Red Cross Society are reported to have accepted the Duke of Newcastle's offer to furnish completely the *Princess of Wales* hospital ship, and that of a private donor, the *Union Steamer Spartan*, with Röntgen apparatus and photographic material. Under the direction of Mr. John Le Conteur, the outfit for the *Spartan* goes with the hospital ship *Princess of Wales* next Thursday.

**SOUTH AFRICA AND THE TRANSVAAL.**—By permission of the Cape Government railways, Mr. J. H. Steward, of 406 Strand, London, has produced a set of slides from photographs of places of special interest just now in connexion with the war in South Africa. Among them will be found some excellent views of Mafeking, Aliwal North, Bulawayo, Colesburg, and bridges over the Orange River and the Modder River.

DR. WILHELM ZENKER died on the 21st ult., after a long illness, aged seventy. He was a distinguished astronomer and physicist, and was the author of the first work on photography in natural colours, his *Lehrbuch der Photochromie* being published in 1868. This work is of special interest, as in it he fully explained the formation of colour photographs by stagnant waves, which is, as is well known, the fundamental theory of Lippmann's well-known work.

**CHRISTMAS LECTURES AT THE ROYAL INSTITUTION.**—The Annual Course of Christmas Lectures, specially adapted for young people, at the Royal Institution, will this year be delivered by Mr. Charles Vernon Boys, F.R.S. The subject will be "Fluids in Motion and at Rest." The lectures, which will be six in number, will commence on Thursday, December 28, at three o'clock. The remaining lectures will be delivered on December 30 and on January 2, 4, 6, and 9, 1900.

**CRIPPLEGATE PHOTOGRAPHIC SOCIETY AND ESSEX AND MIDDLESEX CYCLING UNION.**—The Annual Photographic Exhibition will be held on December 5, 6, and 7, at the Cripplegate Institute, Golden-lane, E.C. Intending exhibitors are reminded that the entries closed on Monday last, the 13th inst., but late entries will be received up to November 21. Twenty-five gold, gold cent e, silver, and bronze medals are offered in the nine classes. Entry forms can be obtained of the Hon. Secretaries, Alfred T. Ward, Cripplegate Institute, Golden-lane, E.C., and George F. Sharp, 31, Sach-road, Upp-r Clapton, N.E.

THE LUDLOW PHOTOGRAPHIC SOCIETY.—Mr. John Herbert Williams of Guildhall, Ludlow, writes: "I have resigned the office of Secretary of the Ludlow Photographic Society, and Mr. W. H. Bessell, of Gravel Hill, Ludlow, is now acting in that capacity. On October 27, Mr. W. Hurt Sitwell, of Ferny Hall, was appointed President. Messrs. H. J. Allcroft, Edward

Wood, A. R. Boughton Knight, Sir C. H. Rouse Boughton, Bart., and the Hon. Lucius O'Brien were appointed Vice-Presidents. Messrs. G. E. Davis, Tilsley Price, J. H. Suttle, W. H. Bessell, and J. H. Williams were appointed Committee; Mr. G. E. Davis, Treasurer. The club now numbers fifty-four members."

THE Edinburgh Photographic Society's Annual Exhibition of photographs will be held in the rooms of the Society, 38, Castle-street, Edinburgh, from Saturday, 10th, to Saturday, February 24, 1900. Entries close on Monday, January 29, 1900. A special gold medal has been offered by the President of the Society for the best picture in the Exhibition, the work of an amateur member. The following classes are open to all (gold, silver, and bronze medals in each class): Class 1, Landscape, seascape, and architecture; Class 2, Portraiture, figure, and animal studies. The Judges are Messrs. G. W. Johnstone, R.S.A., Edinburgh; Percy Lund, Bradford; John Stuart, Glasgow. All communications should be addressed to the Secretary, Mr. J. S. McCulloch, W.S., at 10A, George-street, Edinburgh.

**ROYAL SOCIETY.**—The following is a list of those who have been recommended by the President and Council of the Royal Society for election into the Council for the year 1900 at the anniversary meeting on November 30:—*President*: Lord Lister, F.R.C.S., D.C.L.—*Treasurer*: Alfred Bray Kempe, M.A.—*Secretaries*: Sir Michael Foster, K.C.B., M.A., M.D., D.C.L., LL.D., and Professor Arthur William Rücker, M.A., D.Sc.—*Foreign Secretary*: Thomas Edward Thorpe, Sc.D., LL.D.—*Other members of the Council*: Horace T. Brown, F.C.S., Captain Ettrick William Creak, R.N., Professor James Dewar, M.A., Professor Edwin Bailey Elliott, M.A., Hans Friedrich Gadow, Ph.D., Professor William Dobinson Halliburton, M.D., Professor William Abbott Herdman, D.Sc., Sir John Murray, K.C.B., Sir Andrew Noble, K.C.B., Professor Arnold William Reinold, M.A., George Johnstone Stoney, D.Sc., George James Symons, F.R.Met.Soc., J. J. H. Teall, M.A., Professor Joseph John Thomson, M.A., Professor Edward Burnett Tylor, D.C.L., and Sir Samuel Wilks, M.D.

**SECCO FILMS (BRITISH AND COLONIAL), LIMITED.**—The statutory meeting of this Company was held at Winchester House, Old Broad-street, on Saturday last, when there was a fair attendance of shareholders. The proceedings were of a formal character, and involved the proposal of a single resolution dealing with an amendment of the original scheme with regard to working capital. This was carried unanimously, after being seconded by one of the shareholders present, who expressed his satisfaction with the prospects of the Company after hearing the lucid statement which had been made by the Chairman, Sir Roger Goldsworthy. The Directors have been meeting weekly, and have devoted much time to the initial work of starting the Company on a satisfactory footing. It is the intention to secure a building at once, and three or four suitable ones, within easy reach of London, are now under consideration. The fitting of the structure ultimately decided upon will not occupy many months, and in the mean time arrangements will be made for supplying the public with film. There is every reason to suppose that, before the photographic season of 1900 opens, the Secco factory will be at work.

At the Yarmouth County Court, on November 10, before His Honour Judge Wilmot, an action was brought by Mr. A. T. Taylor, solicitor of Yarmouth, against Mr. George Brewer, a photographer of the same town, to recover possession of some photographic negatives under somewhat singular circumstances. The evidence was to the effect that, at an auction sale, the defendant purchased about 5000 negatives, among them being the negative of plaintiff, his wife, and his mother, all of which plaintiff asked should be returned to him. The negatives were taken by Messrs. Boughton in 1895, and they passed to their successors, Messrs. Tilley, and, when the auction of the photographic effects took place, the defendant purchased the negatives amongst other things. The plaintiff had applied to the defendant for the negatives to be returned to him, but the defendant had declined to do so unless he was paid for them. The plaintiff submitted to His Honour that the negatives belonged to him. Mr. Clowes, who appeared for the defendant, contended that they belonged to the defendant, although he admitted that the plaintiff might have the right to reproduction. The defendant said that, when he purchased the negatives, a lot of them were broken, and others had been stolen. They were not classified, and it would take him six months to make a search. It was not the custom of photographers to give up the negatives unless a special contract was made when the sitting took place. His Honour said he was clearly of opinion that the negatives were the property of the customer. It was just the same when one had a plate engraved for cards. He thought a case had been decided, in which it was held that the property in the negative passed to the sitter. However, as it was a somewhat important point, he would adjourn the case for a month, and look up the authorities on the subject.

## Patent News.

THE following applications for Patents were made between October 30 and November 4, 1899:—

"APPLIANCE."—No. 21,696. "An Improved Appliance for use in Photographic Processes." H. C. ST. PHENS.

COPYING APPARATUS.—No. 21,783. "Improvements connected with Photographic Copying Apparatus." B. J. HALL.

CINEMATOGRAPHIC APPARATUS.—No. 21,863. "Improvements in Kinematographic Apparatus." J. A. PRESTWICH.

CINEMATOGRAPHIC APPARATUS.—No. 21,880. "Improvements in or relating to Kineticoscopic or Cinematographic Apparatus." W. FRIESE-GREENE and F. Z. MAGUIRE.

CAMERAS.—No. 21,873. "Improvements in and relating to Photographic Cameras." Complete specification. H. SMYTH.

PRINTING APPARATUS.—No. 22,017. "Improvements in Image-forming Mechanism, chiefly designed for use in connexion with Photographic Printing." F. H. RICHARDS.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

November.	Name of Society.	Subject.
20	Bradford Photo. Society	Demonstration: Wellington Film. Harry Wade.
21	Cripplegate Photo. Society	Viccol P.O.P. T. Thorne Baker.
20	Ealing	Demonstration: Sandell Perfect Films. J. T. Sandell.
20	South London	Excursion Slide Competition.
20	Stafford Photo. Society	Sale of Papers, &c.
21	Birmingham Photo. Society	Home Portraiture. Harold Baker.
21	Gospel Oak	Demonstration: Viccol Paper. Berger & Co.
21	Hackney	The Pictorial Treatment of Lantern Slides. J. A. Hodges, F.R.P.S.
21	Royal Photographic Society	Architectural Photography. Henry W. Bennet.
22	Ashton-under-Lyne	Demonstration: The Carbon Process. Harry Wade.
22	Croydon Camera Club	The Gravura Printing Process. A. C. Baldwin.
22	Photographic Club	Demonstration: The Secoco Film. Messrs. Whitney, Graff, & Co.
22	Southsea	Demonstration: Dektol, and other Eastman Specialities. Percy Hume.
22	West Surrey	Developing P.O.P. C. Sheed.
23-25	Kingston-on-Thames	Fourth Exhibition of Members' Work.
23	Liverpool Amateur	Demonstration: Intensification and Reduction. Harry Wade.
23	London and Provincial	Lovestoft and Neighbourhood. H. Vivian Hyde.
24	Bristol and West of England	Demonstration: The Platinum Printing Process. W. H. Smith.
24	Croydon Microscopical	Trial Night for Members' Slides.
24	West London	Beginners' Meeting: Apparatus. L. Selby.

### ROYAL PHOTOGRAPHIC SOCIETY.

NOVEMBER 14.—Ordinary Meeting.—The Right Hon. the Earl of Crawford, K.T. (President), in the chair.

#### THE SOCIETY'S NEW HOUSE.

This being the first meeting of the Society in its new premises, the PRESIDENT welcomed the large assemblage of members who were present, and expressed the hope that they were all as well satisfied with the accommodation afforded as he was himself.

#### GENERAL BUSINESS.

Forty-seven new members were elected, and thirteen candidates for membership were nominated.

The PRESIDENT announced the admission to affiliation of the Glasgow Photographic Association, the Brentford Photographic Society, and the Banbury District Photographic Society.

At the conclusion of the formal business, the meeting was adjourned.

#### TRAILL TAYLOR MEMORIAL LECTURE.—"TEACHINGS OF DAGUERRETYPE."

Mr. A. Haddon then took the chair, and

Major-General J. WATERHOUSE, I.S.O., proceeded to deliver the second Traill Taylor memorial lecture, the subject being "The Teachings of Daguerreotype." The process, he said, was for a long time considered as unique and without any intimate connexion with the ordinary photographic methods, but Carey Lea was among the first to show that this view was erroneous, and that the Daguerreotype image is subject to the same laws as govern the wet-collodion and other processes for making negatives. The lecturer had last year gone further in this direction, and the result of his investigations went to show that the process might be regarded as an epitome of the photo-plate, and from this point of view it was of special value, because it depended upon the employment of haloid salts of silver, formed by the direct union of the halogen and the metal. This being the case, a good deal of valuable information should be derived from a careful investigation of the process in its various modifications with different halogens or combinations of them, and with different methods of developing and dissolving away the images formed by the action of light. After describing the Daguerreotype process, General Waterhouse said one was first struck by the fact that the sensitive surface of the plate was formed by the direct combination of halogens, iodine, bromine, or chlorine, with the silver of the plate, and the question arose, to which of these elements was the sensitiveness due? Moser's researches on the sensitiveness of silver to light were considered, and the lecturer detailed his own experiments in confirmation of them. He had also obtained some very interesting results with silvered glass plates formed with peroxide of hydrogen before exposure, and found that it was capable of acting in the same way as iodine in sensitising the plate. Nearly all the photographic phenomena, such as the development of an invisible image, the production of a visible image, reversal on development, and the effects of pressure in producing a developable image, could be shown on a plain silver plate. After discussing the properties of the halogens generally used in combination with silver, and the combinations of halogens with silver, the composition of the sensitive surface of the Daguerreotype plate was dealt with. That it is formed by one of the lower compounds of silver and iodine, and not of the pure iodide, was, he thought, shown by the fact that, if a thin film of silver leaf or of silver on glass were iodised till all the silver combined with iodine, there would be produced an almost transparent pale yellow film, which would not visibly darken, even in bright sunshine, and which would require a very long exposure to yield even a developable image. Professor Meldola had suggested that the silver iodide on the Daguerreotype plate formed its own sensitiser, a view with which General Waterhouse concurred. The phenomena known as Talbot's iodine

rings next received attention, the lecturer stating that it was not clear to him to what the vivid colouration was due, unless it were a molecular change in the structure of the film caused by the passage of the iodine vapour along it. The results of Professor J. W. Draper's investigations upon the subject of the relative sensitiveness of the various tints produced on the surface of the Daguerreotype plate by the vapour of iodine were quoted and discussed, together with the late Dr. H. W. Vogel's discovery of the modern system of orthochromatic photography and the application of "optical sensitisers" to the ordinary photographic dry plates. Turning to the developing action of red and yellow light, the lecturer said that one of the most curious phenomena connected with the early working of Daguerreotype plates was the action of red or yellow light upon the images formed either in the camera or by printing out. If a short normal exposure were given to an iodised silver plate, and if it were then exposed in the sunlight under a red glass for about twenty minutes, a completely printed-out image would be produced. The question of the action of light upon a surface composed of pure silver iodide was finally considered, and the researches of Schultz-Sellack, Scholl, Arrhenius, Hunt, Abney, Meldola, and others, were very fully detailed and compared with the observations of the lecturer.

General Waterhouse's lecture was of a most exhaustive and comprehensive character, and it is impossible to do more on this occasion than briefly indicate, as we have endeavoured to do above, the lines upon which he treated the subject. It will be regarded, we think, as a masterly exposition of a very complex question, and one which will form a worthy memorial to the eminent photographer with whose name it is associated.

After a few remarks by the CHAIRMAN, Mr. CHAPMAN JONES, and Mr. J. SPILLER, to which General WATERHOUSE replied,

The CHAIRMAN presented the lecturer with the Traill Taylor Memorial medal, and also handed to Mr. T. R. Dallmeyer a similar medal in respect of his lecture delivered in 1898 on "Focometry and a Focometer."

#### COMING EVENTS.

November 21, "Architectural Photography," by Mr. H. W. Bennett. November 28, "Practical Three-colour Lantern-slide Making," by Mr. E. Sanger Shepherd. December 5, "Lincoln Cathedral," by Mr. Frederick H. Evans (Lantern Evening).

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 9.—Mr. J. S. Teape in the chair.

Mr. BALDWIN, on behalf of the Paget Prize Plate Company, described the new Gravura plates and paper. The nature of the new materials may perhaps be best denoted by the statement that they resemble very closely the now well-known Velox specialities. The emulsion is one which gives, by simple development and every certainty, a great variety of colours, ranging from blue-black through rich browns and sepias to brilliant red chalk. Mr. Baldwin said he was able to show, for the first time, another departure from the usual thing in the form of Gravura opals, a plate that was only just being put upon the market. With reference to the use of Gravura productions, he had been often asked to name the best form of light for making the exposure to. His answer was that any light suitable for bromide work was suitable for Gravura: daylight, gas-light—plain or incandescent—the electric light, or, last but not least, serviceable, magnesium ribbon. Magnesium ribbon, he thought, provided the best fixed quantity of light, and it could be carried about so conveniently. The primary point of attraction for Gravura is, doubtless, that its manipulations may be conducted in an ordinary gas-lighted room or in dim daylight. This quality naturally presupposes that the emulsion is a slow one. As a matter of fact, exposure for black tones (which require the shortest exposure) will probably range from one to two minutes at four inches from the usual household gas flame. To daylight, according to its intensity, from one second upwards in diffused light a few feet away from the window would do, or an inch of magnesium ribbon burnt at a distance of a foot or more. Mr. Baldwin showed the capabilities of paper, opals, and lantern plates by a practical demonstration, producing positives covering fully the range of colour claimed for the specialities. The rule for the production of warm tones is that the exposure suitable for black is considerably increased, and the developer correspondingly restrained and diluted. The developer for black tones is in a concentrated form, and is a hydroquinone-metol formula. It can be purchased in sealed tubes ready mixed, and only requires breaking into four ounces of distilled water. The need for distilled water was often called into question, but Mr. Baldwin would say that, whatever one mixed with his whisky, give him distilled water for his Gravura operations. He showed a series of prints from one negative showing the many shades of colour one could get by systematically varying one's methods. Taking the exposure for black tones as one, that for red chalk, the longest, would be eight to ten. The concentrated developer has to be diluted, variously for the several colours, until 1 ounce is mixed with 20 ounces of water for the red chalk tones. It requires also the addition of a quantity of "A. C. solution," so called, made up of ammonium bromide, ammonium carbonate, and water. This latter solution is employed for all warm tones. The opals require exactly the same treatment as the paper. The negative should best be one tending towards softness, as the emulsion itself has a contrary leaning.

The demonstration which accompanied Mr. Baldwin's remarks was very instructive, and the examples spoke well for the paper, the opals, and the lantern plates.

Mr. WALTER D. WELFORD entered briefly into an account of his experiments on the question of the continued use of developing solutions, especially in regard to ortol. He had succeeded in developing 33 quarter-plates, two at a time, in 2 ounces of solution, taking altogether a period of 72 minutes. He had afterwards developed 19 half plates in 2 ounces of solution, one at a time. The first quarter-plate was finished in 2 minutes, the seventh in 3 minutes, the twelfth in 7 minutes, the twentieth in 9 minutes, the twenty-fifth in 9 minutes, and the thirty-third in 9½ minutes, showing a gradual increase of time with the repeated use of solution. The first half-plate took 2½ minutes, the nineteenth took 10 minutes. He would challenge anybody to differentiate between the first and last. This quality of the solution of remaining efficient for so long was, of course, only good for correct exposures.

The CHAIRMAN thought that in general work it would be found inadvisable to use a solution so repeatedly.

Mr. S. H. FRY, as one opposed to the use of a solution more than once, said it was not so much upon the question of possibility that the discussion really centered as upon advisability.

Mr. WELFORD asked why not, when one could get a good and proper result?

#### PHOTOGRAPHIC CLUB.

NOVEMBER 8.—Mr. J. W. Mason in the chair.

Mr. FOXLEE showed some enamels made in 1864 by Lafon de Camarsac.

Mr. WELFORD, who had lately given his special attention to ortol, and who had already previously addressed the Club on the subject of this developer, mentioned the great economy with which the same could be worked as compared with other developers. His first experiment revealed the fact that thirty-three quarter-plates could be developed with two ounces of solution, and, on a later occasion, he even managed to develop nineteen half-plates with the same quantity of ortol developer. The only trouble he experienced was the gradual diminution of the bulk of the solution, which only measured nine drachms when the nineteenth half-plate had been developed. The last negative was just as perfectly developed as the first, although it required a much longer time to finish it. The plates used for this experiment were, of course, all properly exposed, or, at least, not under-exposed. Mr. Welford thought that, in the case of a series of absolutely exactly exposed negatives, where no restrainer was necessary, the developer could even be used more often. A further peculiarity of ortol was that, when making up the solution, it was not necessary to be so very exact about the proportion of the various chemicals used as in the case of other developers, except with regard to the quantity of bromide, which must be increased when no sulphite is used, and *vice versa*. Mr. Welford found that ortol was one of the best all-round chemicals in the dark room. He thought it most likely that ortol would eventually replace pyro. Used in a normally strong solution, it will not stain the fingers in the least. Speaking of his experiments with the new developers generally, Mr. Welford had come to the conclusion that the addition of the reagent does not quicken development at the same rate as pyro would if used with soda, and he thought this question was well worth closer examination.

Mr. MACKIE brought to the notice of the Club the case of two negatives of the same subject which had received the same exposure, and one of which was treated with a solution of one grain of pyro and twenty-four grains of soda per ounce, whilst the developer used for the other contained four times the quantity of pyro to the same soda solution. Contrary to what one would expect, the developer richer in pyro made the image appear more slowly than the poorer solution, but finished the picture in a shorter time.

The CHAIRMAN having asked the opinion of members on the Agfa intensifier, it was found that the same had not been extensively used, but the few trials had revealed the fact that it acted comparatively slowly.

Mr. TOTTEM stated that he had very satisfactory results with Antogene, both as an intensifier (followed by redevelopment) and as a reducer (followed by hypo).

Richmond Camera Club.—The meeting on November 6, to which ladies were invited, was devoted to

#### A TOUR THROUGH ITALY, SPAIN, AND ALGERIA,

illustrated with a large number of very beautiful slides by Mr. H. LITTLE, who described the various subjects as they appeared on the screen. At the conclusion of the meeting a hearty vote of thanks to Mr. Little for the very interesting evening's entertainment he had afforded the Club was passed with applause.

#### FORTHCOMING EXHIBITIONS.

1899.

- November 17 ..... Hackney Photographic Society. W. Selfe, 70, Paragon-road, Hackney, N.E.  
 „ 17-19 ..... Philadelphia Photographic Salon. Foreign Representative, A. Horsley Hinton, 1, Creed-lane, E.C.  
 „ 20-25 ..... Longton and District Photographic Society. Thomas Mottershead, 43, Stafford-street, Longton, Staffordshire.  
 „ 27-Dec. 18 American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.

December 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

„ 11-Jan. 1900 Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.

„ 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.

1900.

January 29-31 ..... Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordinance-row, Portsea.

April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE PRINCIPLES OF DEVELOPMENT.

To the EDITORS.

GENTLEMEN,—In the brief summary you gave in your last issue, p. 716, of Mr. Watkins' paper on the above subject, I note that in the second paragraph of your article it is stated:—

(a) "Longer development, as a general rule gives greater contrasts."

(b) "It was a common belief that over-exposure led to thinness of results, but this was a mistake, for full development would ensure enough density to meet all needs."

(c) "There is for every plate a minimum exposure below which there is no developable impression made upon its sensitive coating, while at the other end of the scale was a maximum beyond which no effort could induce further effect."

(d) "A common belief was that metal had the power of bringing out the upper tones of the negative more quickly than any other developer. His experiments showed that all developers act in much the same ratio."

First as to paragraph (c), while the first section is axiomatic the second requires modification, for, while quite correct as to exposures within limits, it must be modified as regards such extreme over-exposure as to cause reversal of the highest lights, as in, say, a window brilliantly lighted and forming part of an interior view.

Then as to the concluding paragraph of (d). No doubt this is correct, the mistaken idea as to the metal being the result merely due to its very rapid surface action.

But, and this is my reason for writing, it seems to me that these considerations and paragraph (a) are mutually destructive.

Keeping the concluding paragraphs of (c) and (d) in mind, let us start to develop first a fully exposed plate; if we stop anywhere short of full development, the ratio of density or contrast will everywhere be in proportion to light action; but, if we continue development until the maximum effect has been produced in the highest lights, is it not evident that longer development must bring up the density of half-tones and shadow detail, and so diminish, and not increase, contrast?

This is still more evident in the case of over-exposure up to the point of reversal, hence I fail to see how (a) can be true as a general proposition. As to paragraph (b), I take it the common experience is that, with over-exposure, not previously known and therefore guarded against, there is such a rapid reduction all over the sensitive surface that ratio of reduction seems lost, or, at any rate, all due balance is, and that a continuation of the action of the developer still further flattens the result, and, while no doubt producing greater density, does not restore the lost balance, so it does not seem to me the statement that "full development would ensure enough density to meet all needs" will bear examination, for it should mean that a sufficient development would give a usable negative of full density, whereas it does give a negative in which all balance or contrast is wanting.

If the reply is that the developer must, before use, be modified to meet the case, this not only presupposes knowledge of the over-exposure, but introduces the wider question of what is over-exposure. Is it not a relative term which can only be discussed as applied to the use of a standard developer?—I am, yours, &c., E. H. MICKLEWOOD.

5 St. Michael's-terrace, Plymouth.

#### AUTOMATIC SLIDE CHANGING.

To the EDITORS.

GENTLEMEN,—In your reply to "C. K. T." (October 27) you quote his question, "Is there any arrangement for the lecturer to press the button and automatically change the slide." Whilst in Dublin 1897, one of the employees of the Dunlop Tyre Company showed me his invention for slide-changing from the platform. Its ingenuity and utility rather impressed me, and it was only fitted up at the place I was then lecturing at. The slides had to be inserted by an attendant at the lantern, but a simple push at the end of an electric wire effected the change. I tried it thoroughly and found it work admirably. The change takes place at the exact moment desired by the lecturer, and saves all signals, &c. After my return to London I received a communication from the inventor, asking for my written opinion of it to lay before a manufacturer or dealer. Since that time, however (1897), I have not seen or heard anything further; but the idea is good, and I hope this letter will catch the eye of somebody with fuller knowledge of the circumstances.—I am, yours, &c., WALTER D. WELFORD.

## AN APPEAL.

To the Editors.

GENTLEMEN,—The Corporation has again granted the use of the Guildhall for the annual banquet to the Ragged School children of London, and the Prince of Wales has once more sent me a donation to, if I may quote the words of His Royal Highness, "the excellent Fund which you are again kindly raising for providing dinners and hampers for the poor and crippled children of the Metropolis at Christmas."

Last year, after providing a banquet at the Guildhall for about 1400 poor children, I was enabled to send 4324 hampers to deserving little cripples, whose affliction very often keeps them prisoners in one-room homes from year's end to year's end.

I trust that, with the renewal of your valued sympathy and assistance, we shall do better still this year by increasing the number of hampers to 5000.

May I ask your readers to help me again this winter to brighten the lives of some of London's little cripples? Subscriptions should be sent to me here, marked "Children's Fund."—I am yours, &c.,

W. P. TRELOAR, Alderman and Sheriff.

Ludgate-hill, London, E.C., November, 1899.

We are happy to insert Alderman Treloar's appeal. It might be possible to provide an optical-lantern entertainment at the Guildhall Banquet to the children; if so, some of our readers would, doubtless, assist.—EBS.]

## CHEAP ENLARGEMENTS.

To the Editors.

GENTLEMEN,—I am pleased to be able to tell you that your congratulations may now be extended from the *Stage* to the *Sun*, the latter journal having withdrawn from its offer of "crayon portraits" the paragraph to which I referred in your issue of the 3rd inst. This result is probably largely due to your editorial comments in the current number of THE BRITISH JOURNAL OF PHOTOGRAPHY, for which the profession will thank you.

I may add that I am quite in sympathy with the desire of a "Photographer of Forty Years' Standing" for more unity and co-operation amongst photographers, though I do not agree with his somewhat pessimistic idea that we are powerless individually. For many reasons combination will be very difficult to obtain, but I think that individual efforts for the benefit of the profession will render it more possible in the long run.—I am, yours, &c.,

DRINKWATER BUTT, F.R.P.S.

35, Keppel-street, Russell-square, W.C., November 11, 1899.

## SPOTS ON MATT-SURFACE PRINTS.

To the Editors.

GENTLEMEN,—Seeing "Collodion's" query in Correspondence column last week re matt-surface prints, it has prompted me to give my experience with this paper.

I also am troubled with spots and markings, as described by your correspondent, which sometimes present themselves next morning, having been toned the previous night, and more often not showing until perhaps a fortnight afterwards, or again three months or so. Looking at several lying before me as I write, they give one the impression that some chemicals were at work underneath the surface of them causing the spots and meanness referred to, although I can assure you that the various manipulations which they are put through are thorough in the extreme, and at the same time all dishes are given a good wash out before commencing to tone, &c. After toning, they receive twenty minutes' fixing in a bath of the prescribed strength, being constantly kept on the move. They then get from two to two and a half hours' washing in running water, during that time receiving from thirty to forty changes by hand from one dish to another. Perhaps some of your kind readers might, by giving us their experiences, be able to help some of their less fortunate workers out of their difficulties.—I am, yours, &c.,

PHOTOGRAPHER.

## THE RECENT EXHIBITIONS.

To the Editors.

GENTLEMEN,—I should like to be allowed to express my approbation of the sentiments expressed by "Free Lance," in your last impression, with regard to the recent photographic Exhibitions. That those whom it may concern will take his remarks to heart, is a "consummation devoutly to be wished."

But, please, Mr. "Free Lance," it is Sir Peter Teazle, in Sheridan's immortal comedy, who says, "Damn your sentiments," not Charles Surface.—I am, yours, &c.,

F. A. BRIDGE.

East Lodge, Dalston lane, London, N.E., November 13, 1899.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

AN AMERICAN (New York).—We are much obliged for your card. Will you not authenticate it with your name and address?

G. BREWER; L. URBINSKY.—The negatives are the property of the photographer. We shall have some remarks on the subject in our next issue.

PHOTOFAD.—Ascertain by practical experiment where the light from the condenser (1) converges to a point and (2) is of the diameter of which the parallel beam is required, and then at 2 insert a concave lens, the focus of which is equal to the distance between 1 and 2.

PRESERVING A POTATO.—CURIO says: "We have had a curio in the shape of a Magnum potato brought to be photographed. Could you inform us how or where the tuber could be preserved or petrified?"—We cannot. Possibly some reader can kindly assist our correspondent in the matter.

ADDRESS WANTED.—BLACKBURN & Co. ask: "Can you give us the name and address of an English wholesale glass and fancy photographic frame and stand-maker?"—Marion's and other large houses supply these goods wholesale and retail. We cannot give the names of English manufacturers.

THE POISONS ACT.—DEALER asks: "Is it against the Poisons Act for a dealer in photographic materials to supply bichloride of mercury, wholesale and retail, either in crystals or in solution? Is it necessary to label 'poison'?"—Yes, unless the dealer is a pharmaceutical chemist. In any case, the bottle or parcel must be labelled "poison."

BOOK OF POSES.—POSING says: "Will you kindly tell me if you know any firm who publishes a book of poses; such a book would be very acceptable to a beginner, as, by studying the various subjects therein, he would at all times get a decent pose?"—Messrs. Dawbarn & Ward, Farringdon-avenue, publish a work on lighting and posing. We should advise you to obtain that.

ROTHENBURG.—COL. GUBBINS writes: "I read in the last JOURNAL an account of a lecture given before the R.P.S. by Mr. Vezey on 'Some Medieval Towns of Germany.' The first town mentioned is Rothenburg. Wishing to know its whereabouts, I looked it up in my atlas, and find that there are no less than four towns of that name: 1, in Bavaria (Middle Franconia); 2, Hesse Cassel; 3, Posen; 4, Silesia. Can you tell me which of these four is the one referred to?"—In reply: Rothenburg in Bavaria, about thirty miles S.E. of Würzburg.

COPYING.—ENLARGEMENT says: "Will you kindly inform me how to make a negative from a cabinet or carte-de-visite photograph without showing the margin of the mount that is always left? Of course, you will know if I get the print only, the full size of the negative, then it takes the head or feet off the figure. I want these negatives for making bromide enlargements, so you see I find this margin a difficulty."—We are afraid we do not clearly understand this query. If the margin of the mount is not desired, it can be covered up with paper. Why the head or feet are cut off when the print only is included, is, we presume, that the plate used for the negative is not large enough to include them.

FORMALIN.—ABBOT PASLINW says: "I should be glad if you could give me a reply through columns of THE BRITISH JOURNAL OF PHOTOGRAPHY with regard to the use of formalin in printing and development. 1. Is formalin (i.e.,  $\text{CH}_2\text{O}$ , forty per cent.) a fairly stable solution, and not prone to decomposition if kept cool in stoppered bottle? 2. In case of P.O.P., is it best to use before toning, as Ilford Company recommend alum? and, in that case, what strength solution, and how long? Is lengthy washing necessary, i.e., has it any effect on the toning or fixing solution? 3. As No. 2, only with regard to status, strength of solution, and before or after fixing?"—In reply: 1. Yes. 2. It is not very important which. The strength is not very important; the weaker it is, the longer time should be given. Rather less washing than with alum will suffice. 3. Again unimportant, but we prefer before fixing. On page 397 of the ALMANAC for 1896 is an article on experiments with formalin. You will do well to read that.

IMPERFECT FIXATION.—J. H. G. says: "1. I shall be glad of your opinion as to the cause of marking on two of the enclosed negatives. The two cabinet vignette negatives were most probably washed in the tank at the same time, and have been stored away together; they were taken about four years ago. I have others taken about the same time that are all right, and others marked, and also marked ones of only two years' old. By the three-quarter length negative you can see it is as much on the glass as the film. The copy negative enclosed was washed in the same way (and all my negatives), but is another maker's plate, which I use for copying. I have looked up several of this make of the same age, and they are in good condition. All my negatives from 1885 to 1893 or 1894 are as good as when taken. Developer used for enclosed plates was pyro ammonia, but those I mentioned of two years ago were pyro and soda. I should be extremely obliged if you can enlighten me on the matter, and (2) at the same time say if you think soda is to be preferred to ammonia for a (developer) person subject to eczema in the hands, and of rather a bad form—in other words, do you think one more poisonous or likely to do more harm to the disease? I thank you in anticipation."—In reply: 1. A careful examination of the negatives convinces us that imperfect fixation is the cause of the trouble. The hyposulphites left in the film have reacted on to the glass, hence the markings on the latter. 2. No difference in the behaviour of the developers named in the circumstances named—that is, so far as we are aware.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING.

THE Thirty-ninth Annual Issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. The volume reaches the unprecedented total of 1512 pages, and is the largest yet published. As hitherto, it will be issued in paper covers, price 1s.; cloth bound, 1s. 6d.

The frontispiece is a bromide print by Messrs. Wellington & Ward, of Elstree, from a negative by Mr. H. Walter Barnett, of No. 1, Parkside, Knightsbridge. Many other illustrations are also given in the text matter.

Eighty articles, on a great variety of subjects interesting to photographers, and contributed by the principal authorities of the day, form a feature of the volume. The other sections are "Epitome of Progress during 1899," "Patented Inventions of the Year," "Miscellaneous Information," "Practical Notes and Suggestions of the Year," which, with the large collection of formulæ, tabulated matter, and a great deal of other information of use to all photographers, places at their disposal,

for constant reference, a fund of technical knowledge which is not to be found in any other photographic annual.

## EX CATHEDRÂ.

We print this week the second Traill Taylor Memorial Lecture, delivered on Tuesday week by Major-General Waterhouse, before an excellent attendance, at No. 66, Russell-square, W.C. The experiments of the distinguished author have covered a wide field, and he was able to tell his hearers of many interesting and unsuspected phenomena to which silvered surfaces give rise. In particular, the distinct resemblances traceable in several respects between plates silvered for Daguerreotype and the haloid salts of silver is a discovery of great value; but the entire lecture teems with chemical and physical data which add materially to our knowledge of the fundamental characteristics of a branch of photography not hitherto fully made clear, and well repays perusal on that account, as well for the new vista of experimental work which it opens up. We shall take future opportunities of referring to General Waterhouse's valuable lecture.

\* \* \*

GENERAL WATERHOUSE'S exposition of the teachings of Daguerreotype worthily succeeds the lecture on "Focometry" given by Mr. Dallmeyer twelve months ago, and the fact that two of the greatest authorities in their respective branches of investigation have already been the recipients of medals for the delivery of Traill Taylor Memorial Lectures may, no doubt, be taken as an indication of the high esteem in which the honour of delivering that lecture will in future be held. It is almost four years to the day that in these pages we suggested that steps should be taken to perpetuate the memory amongst photographers of our late friend and predecessor, and we are very gratified to feel that the annual lectureship which constitutes the memorial has been so firmly established in general favour, and gives promise, as time goes on, of largely adding to our photographic knowledge, to which, during his long association with this JOURNAL, Mr. Traill Taylor made so many valuable contributions. A word of thanks should here be passed to the Memorial Committee for their labours in the matter; but above all to Mr. Philip Everitt, who has devoted a

very great deal of time and trouble as Honorary Secretary, the best thanks of the subscribers and all interested in the Memorial are distinctly due.

\* \* \*

IN another part of this week's JOURNAL we print the report of a demonstration of a "new method of artificial lighting for portraiture," given at a recent meeting of the Croydon Camera Club, by Mr. W. H. Smith of the Platinotype Company. The system takes advantage of the combustion of magnesium in oxygen for obtaining illumination of such great power and brilliancy that studio exposures of one second, or even the half or quarter of a second, may be given and results obtained which are indistinguishable from portraits made by the aid of daylight. A considerable number of specimen prints from negatives produced by the new system of lighting have been shown to us, and we have no hesitation in stating that they are such as would well pass for first-rate daylight work.

\* \* \*

WE shall shortly give a fuller description of the new method of magnesium lighting about to be introduced by the Platinotype Company, but its main features may here be briefly summarised: Imagine a room lined with paper for the purpose of diffusing the light. The source of illumination is magnesium ribbon suspended in a vessel containing oxygen, and ignition is obtained by electrical means. The supply of oxygen gas into the combustion chamber is automatically controlled, and a hundred exposures may be made by means of one foot of the gas. The cost of a single exposure is as low as a fraction of a penny, and the total expense of the installation will, we are assured, be within the reach of all. As we have already mentioned, the Platinotype Company, of Bloomsbury-street, will shortly place the new lighting system on the market. On the data laid before us we have formed a very high opinion indeed of the latest method of using magnesium for artificial-light portraiture. In the course of each year large numbers of photographers ask us to recommend them a cheap and effective system of working in the studio independently of solar light. The Platinotype Company's new system should therefore meet a wide range of requirements. In the dull weather recently experienced all over the country, it would, no doubt, have been found of the very highest value and convenience. Public demonstrations of the new light will shortly be given at the Platinotype Company's offices, Bloomsbury-street, London.

\* \* \*

By the kindness of Mr. Horace Wilmer we are enabled to print the following eulogy of the late W. K. Burton, which recently appeared in a Far Eastern contemporary: "In the death of Professor W. K. Burton, Japan has lost an efficient helper and the foreign community a most genial friend. A man of eminently good family stock, of high scientific training and attainment, of extraordinary nervous energy, and of an open and generous disposition, he has succumbed to the defects of his qualities. At home he might easily have grasped eminence and success. Here he has fallen an early victim to the peculiar social conditions and climatic influences which, in this so-called Lotus-land, keep the nerves in the highest state of tension, and thus quickly exhaust men of his temperament. His loss will be keenly felt by all who have known him."

It is reported in one of our contemporaries that a remarkable collection of films for moving picture machinery is now being developed at the laboratory of Mr. Edison. The pictures are of the Klondike, and are intended for the exhibit Mr. Edison is to make at the Paris Exposition. The entire series will show actual life in the Klondike as it has never before been shown. The positive pictures on the film are nine times the size of the ordinary ones, and, in order to use the larger film, it was necessary to reduce the speed of the camera from forty-five to twenty pictures a second.

\* \* \*

*South Africa* gives the following item of curious information relating to the manufacture in Paris of war photographs to order: The persons who happened to be in the Buttes-Chaumont Park the other afternoon were astonished to see a group of English soldiers occupying the top of a knoll. The men were ranged as if expecting an attack, some of them placed as advance sentinels, others taking advantage of the cover afforded by trees, and the remainder ranged in firing order along the crest of the slight eminence. Presently a "commando" of Boers surged out from below, opened fire on the English, and proceeded to storm the hill. For a moment the spectators were inclined to wonder whether the English and Dutch residents in Paris had decided to settle their differences by mortal combat. In any case, what was afoot was sufficiently mysterious until the truth was explained. The editor already mentioned is desirous of giving his readers realistic photographs of the Transvaal War, taken, of course, by a special correspondent. Genuine photographs of this kind would naturally be difficult to obtain, so the editor had hit on the idea of dressing up a number of theatrical "supers" as English and Boers, of making them go through a series of military operations, and of having photographs taken of the scenes thus contrived. In consequence, Londoners must not be surprised if they shortly obtain, *via* Paris, what purport to be Kodak reproductions of the wounding of General Symons, and other prominent incidents of the war. There seem to have been no mules at the Buttes-Chaumont, or doubtless the famous stampede would figure in the series of pictures.

#### THE RIGHT TO THE NEGATIVE.

ONE would have thought, from the number of times this matter has been settled in law courts, and in favour of the photographer, that we had heard the last of it. Not so, however, for it has cropped up again, as was seen by a report in our last issue, of a case in the Yarmouth County Court, before his Honour Judge Wilmot, where a Mr. Taylor, a solicitor, sued Mr. Brewer to recover possession of some photographic negatives under what are termed "singular circumstances." Well, they are singular.

Briefly they are these: A, in 1895, has some portraits taken by B. B, after a time, sells his business and negatives to C. C, some time afterwards, disposed of his stock at auction, and the negatives were purchased by D, the defendant in the present case. Now A is suing D for the negatives from which B supplied the portraits. The lay mind would naturally have thought that if A had any cause of action at all, it would have been against B, the only one with whom he had dealings, and not D, who bought the negatives at an auction years afterwards. But we suppose that such is not the case,

as this point does not appear to have been raised. It may be, however, that the photographer, instead of raising any legal quibble, preferred to defend the action on its merits, i.e., that the negative is the property of the photographer who takes it, as it has been proved to be over and over again.

There is an unwritten law, "custom of trade," which has great weight in law cases. From the very earliest days of photography the negative has always been considered the property of the photographer, and not of the sitter. One of the old arguments urged has been the custom with card plates, but it is not analogous. Here a charge is made for plate, and so many cards so much. The plate, by the "custom of trade," and as a distinct charge made for it, is the property of the customer; but, if the cards were printed by letterpress or lithography, the customer has no title to the forme or stone used any more than he has to the lasts upon which his boots are made, unless, indeed, he has specially paid for the lasts to be made; then, of course, they are his property. In the case now before the Yarmouth County Court the Judge is reported to have said that he was clearly of opinion that the property of the negative rested with the customer, and not with the photographer, adding, that "he thought there was a decided case in which it was held that property in a negative passed to the sitter, but he would adjourn his decision for a month to look up the case."

As two or three correspondents have written of late, asking if we could quote a case where, in Court, it had been definitely decided that the negative is the property of the photographer, we have been at some trouble to do so, though we are aware that we are not quoting all.

*Pedro v. Deane*, tried in the Bloomsbury Court, July 24, 1876 (see p. 359 of our volume for that year). Photographer sued for thirty shillings, price of a dozen cabinet portraits. Claim resisted because the negative was not given up. Judgment for the photographer for the full amount claimed and costs.

*Dixon v. Ward*, tried in the same Court, July 23, 1880 (see p. 372 of the JOURNAL for that year). The claim was for 4*l.*, being the value of two proofs and of the negative itself of a pianist he was instructed to photograph. Claim resisted as being excessive. Judgment entered for the plaintiff, His Honour remarking that the defence set up could not be maintained, for the negative of a picture was the most valuable property in it, as by it the defendant could have any copies printed by another photographer.

*Andrews v. Capper*, tried in the Swansea County Court, March 21, 1884 (see p. 202 of the volume for that year, also comments on the case, p. 210). In this case the claim was for 5*l.* 8*s.* 6*d.* for photographing a vessel, and 5*l.* 3*s.* for the copies supplied. The defendant paid for the copies, but resisted the claim for the former sum unless the negatives were handed over to him. Judgment for the plaintiff with costs. In his remarks the Judge said, "If you order a photograph, unless you make special terms for the purchase of a negative, the photographer is not entitled to give it up." The defendant's counsel asked, if a photographer charged him for taking a negative, did it not belong to him? The Judge replied, "No; it is part of the instruments used in the business. It is what the photographer uses in his business to make photographs. Why should he part with the instruments of his trade? A negative may be a secret in his trade."

*Theobald v. Thomas*, tried in the Brentford County Court,

in February 1895 (see p. 114 of our volume for that year). Facts: Messrs. Theobald & Co. were in the practice of sending specially drawn subjects and prints to the defendants to copy and make lantern slides from. Eventually the Messrs. Thomas sold their business, with the negatives, to Mr. Tyler, and Messrs. Theobald had to pay that gentleman 11*l.* 1*s.* 5*d.* to obtain the negatives, which they alleged were their property. That sum the plaintiffs sued the defendants for, together with 6*l.* damages for the loss of sale of slides. In the result the Judge, after hearing witnesses as to the custom of trade in photography, found for the defendants on all the issues, with costs, adding "that he failed to find that there was any custom in plaintiffs' trade different to that in the general photographic trade, where the negatives are held by the photographer though he could not use them as he chose." It will be noted that in this case the plaintiffs proceeded against the one who took the negatives, instead of, as in the Yarmouth case reported last week, against the one who purchased them.

The Edwards' case, tried in the Lambeth County Court, March, 1896 (see THE BRITISH JOURNAL OF PHOTOGRAPHY, p. 194, for the volume of 1896). In this case the late Mr. Edwards was sued by a monumental mason for damages for the detention of eighteen photographic negatives. The negatives, it appeared, were taken in the ordinary course of business, and the plaintiff contended that they were included in the charges and were his property. But the Judge (Judge Emden) said that "there is a decisive case on this very matter, and he well remembered it, as he was counsel in the case, and by the decision the photographer was held to be the owner of the negative." Judge Emden also said "that there was no evidence that there was a special contract, or that the negatives were specially paid for," adding that, "if the plaintiff's solicitor's contention was right, a person sitting for portraits should be entitled to the negative." In the end the judgment was for Mr. Edwards, with costs. On the question of appeal the Judge made the significant remark "that the plaintiffs should take time to consider the matter."

Although the cases cited above are only County Court ones, they stand as precedents, and confirm the fact that the negative is undoubtedly the property of the photographer, unless there is a special contract to the contrary. There is also a case (*Pollard v. The Photographic Company*, 1888), tried in a superior Court—the Chancery Court—before Mr. Justice North, as confirming the fact that the negative belongs to the photographer. In this case there was no question raised as to who the negative belonged to, but whether the photographer was entitled to use it, except to the order of the sitter. Mr. Justice North, in giving judgment, appeared to fully recognise that the negative was the property of the photographer, for in his ruling he said that the arrangement between the customer and photographer included by implication that portraits taken from the negative should be appropriated to the customer only. He granted an injunction to restrain further use, with costs.

It will now be interesting to see what will be the decision in the Yarmouth County Court case.

---

**Technical Education.**—Reference is frequently made in the English press to the advantage that our German cousins possess in the way of technical education, and it has also been referred to in these columns when different technical schools have been opened here. There is no question that, up to quite recently, tech-

nical education, including photography, has been much neglected, but now it is receiving more attention. The report of the Technical Education Department just issued shows that the amount spent on technical education in London during the September quarter was 24,897*l.*—about 100,000*l.* a year for London alone—a goodly sum, it must be admitted. But the point for consideration is this, Is the amount of really practical education imparted equivalent to that obtained in Germany for a like sum or for a far less amount? The sum expended in such matters as education must not be taken to represent, at least in this country, the value received; still, it shows that the subject is receiving attention, and that is some satisfaction.

**X Rays on the Battlefield.**—It will be remembered that last week we commented in *Ex Cathedra* on the absence of the Röntgen-ray apparatus in previous campaigns, and on the replies given when questions on the subject were asked "in the House." It is satisfactory now to learn that the apparatus is in actual use in the field though provided by the Natal Government. In the *Standard of Friday* last is a telegram, through Reuter's Special Service, dated Pietermaritzburg, November 15, which reads: "The Natal Government's Röntgen-ray apparatus is doing splendid work among the wounded here, in locating the position of bullets which it was impossible to find with less powerful apparatus." From this it is clear that the Natal Government were fully alive to the value of Röntgen's discovery, and are utilising it, and to its full advantage. It is to be hoped, and we believe it is the case, the Medical Corps now arriving at the seat of war are as fully equipped with the apparatus as the Natal men are, for there is no question as to its great value.

**A Wonderful Sight.**—A report which is going the round says there is a boy, aged eleven, in Massachusetts, who is endowed with a wonderful sight. It is asserted that this will penetrate substances in the same way as the X rays. His gift, so it is said, has made him very useful to doctors in cases of accident and other mishaps where it has been found necessary to examine the interior of a patient's body. It should be borne in mind, however, that this story comes from America, where they often have wonderful things. We have an idea that we have heard a similar tale before.

**Art Pictures in the Lantern.**—It may be remembered that a few years ago we suggested that some of the foreign houses who make a speciality of art reproductions—the old masters as well as modern pictures—would do well to issue lantern slides of them as well as paper pictures, and that they would probably command a large sale in this country, and in the States, where the lantern is more in evidence than it appears to be on the Continent. It is with pleasure that we now see that Messrs. Eyre & Spottiswoode have just announced that they have had prepared the following four lectures, illustrated with lantern slides: "Gems from the Galleries: an evening with the Masterpieces of the World's Art;" "Through Shot and Shell: an illustrated lecture of Nelson;" "The Romance of a Reign: Victoria, Queen and Empress;" "The Bible and the Monuments: Parallels to the Illustrations of the Bible Story." Last year Messrs. Braun & Co. announced that they were issuing some thousands of their well-known art reproductions as slides for the lantern, and we were glad to hear it.

**A Boon to Continental Tourists.**—Photographic tourists on the Continent often feel considerable anxiety as to how their packages of dry plates will be dealt with at the foreign Customs Houses, particularly if they do not speak the language of the country. They will now feel gratified that the London, Chatham, and Dover Railway Company, in conjunction with the Western of France Railway Company, have arranged with the French Customs officers at Victoria so that passengers *via* the Newhaven and Dieppe route may have their registered luggage cleared prior to their departure for France. This new convenience, it is expected, will

take effect in January next. The advantage of this arrangement is that the tourist may have his photographic paraphernalia examined and passed before he starts, so that it will not necessitate its examination at the French Customs, and of course it will only have to be again examined on his return here. This new regulation will relieve him of great anxiety, particularly, as we have just said, if he does not speak French.

**The Leonids.**—The celestial fireworks, as the Leonids are often termed, seem to have been a failure this time, though great preparation was made for viewing them as well as photographing them, and all through the weather. Oh, that Clerk of the Weather! In all countries the weather seems to have been generally unpropitious, according to telegrams from Vienna, Berlin, New York, &c. At Hamburg, however, 149 were counted, including fifteen of the first magnitude, which were photographed, and at the Yale Observatory about a dozen were photographed. With the object of viewing the Leonids from a height and photographing them, the Rev. J. M. Bacon, accompanied by his daughter and Mr. Spencer, the well-known aeronaut, ascended in a balloon from Newbury. They, however, had an unfortunate experience during the twelve hours the balloon was up, for part of the time the machine is reported not to have been under control. Finally it came to earth near Neath so suddenly that one of Miss Bacon's arms was fractured, and the reverend gentleman was considerably shaken. The balloon rose to 9000 feet, and a most perfect observation was made of the simultaneous setting of the moon and the rising of the sun.

#### TEACHINGS OF DAGUERRETYPE.

THE TRAILL TAYLOR MEMORIAL LECTURE.—No. II., 1899.

WHEN I had the great honour of being invited by the Committee of the Traill Taylor Memorial to deliver the second of the series of Memorial Lectures, it became a question what subject I could best deal with and would be most appropriate.

Three presented themselves:—

1. "The Evolution of the Process Block," which was a subject in which our lamented friend, Mr. Traill Taylor, took himself a deep personal interest.
2. "The Relationship of Colour to Sensitiveness," which would have dealt with colour photography.
3. "Teachings of the Daguerreotype," which is the subject selected by the Committee for the present lecture.

The first lecture, given by Mr. T. R. Dallmeyer, was connected with the optics of photography in relation to the lens, which is the first requirement in the practice of the art with the camera.

The second requirement is the sensitive plate, and I now propose to take you back to the consideration of the earliest sensitive photographic plates in which silver haloid compounds were used.

#### VALUE OF DAGUERRETYPE AS A TEACHING PROCESS.

Although Daguerreotype has long been abandoned, it is capable of teaching us a good deal about the action of light on the silver haloid compounds which form the basis of our modern dry plates, as Professor Meldola has pointed out in his *Chemistry of Photography*. It may therefore well form the starting point of lectures in the present series, dealing with photographic processes based on salts of silver.

Daguerreotype was for a long time considered a unique and perfectly special process without any intimate connexion with the ordinary photographic processes, and, of course, so long as mercury alone was used for the development of the invisible image on the silver plates, it was so to a very great extent. Carey Lea was among the first to show that this view is erroneous, and that the Daguerreotype image is subject to the same laws as govern the wet-collodion and other processes for making negatives. Last year I was able to go further in this direction and show that Daguerreotype plates could be developed in a practical way by the ordinary acid ferrous sulphate and silver, or acid pyrogallol and silver used for wet-collodion plates, as well as with ordinary dry-plate developers, though in this latter case only faint negative images were produced. I also showed that the sensitive surface of iodised or bromo-iodised silver could be rendered more sensitive by treatment with suitable organifiers or halogen absorbents, such as tannin and similar bodies, as in the old dry-collodion processes, and that they could be rendered orthochromatic or colour-sensitive by treatment with suitable dyes, like collodion or gelatine plates. The process may therefore be looked upon as an epitome of the photo-plate, and from this point of view is of special value, because it depends upon the employment of haloid salts of silver formed by the direct union of the halogen and the metal, and therefore in their most

simple and purest forms as regards freedom from organic mixtures and complications.

This being the case, we ought to be able to derive a good deal of valuable information from a careful investigation of this process in its various stages and modifications with different halogens or combinations of them, and with different methods of developing and dissolving away the images formed by the action of light. From such an examination I think we ought to be able to obtain fuller knowledge of the probable nature and method of formation of the invisible developable image; and, even if we do not succeed in this, we may, at any rate, acquire information which may be of use in future investigations. The subject is one of considerable difficulty, and one which I feel requires very much fuller special knowledge and more time and attention than I have been able to bestow upon it. In fact, I have only been able to carry out a small part of the programme I sketched out above.

#### DESCRIPTION OF DAGUERRETYPE.

For the benefit of those among you who may not know how Daguerreotypes are produced, it may be briefly stated that a very highly polished surface of silver, either alone or plated on copper, is made sensitive to light by exposure to the fumes of iodine and bromine, with or without an admixture of chlorine. After a suitable exposure in the camera, which, even at its best, is very considerably longer than is necessary with a gelatine plate of ordinary rapidity, the plate is exposed to the warm vapour of mercury, which condenses and attaches itself only to those parts upon which the light has acted, and in proportion to the intensity of the action and the length of exposure, up to a certain limit. In this way an image is obtained in which the lights are formed by a white, powdery amalgam of silver and mercury, while the shadows are formed by the highly polished silver surface, which appears black in contrast with the whiteness of the amalgam when held in a suitable light. This effect is heightened by the process of gilding, which at the same time fixes the powdery image to the plate and makes it less susceptible of injury.

I have here some very beautiful specimens of Daguerreotypes, taken many years ago in the Crystal Palace, by the late Mr. C. Matheson, and presented to the Royal Photographic Society by Messrs. Negretti & Zambra. They will give you a good idea of the results obtainable.

It is not necessary, at any rate for experimental purposes, to use silvered copper plates. Glass silvered by the ordinary silvering processes answers very well for most purposes, and is cheap and readily obtainable. It can easily be polished with a little rouge or *well-washed* tripoli powder, on a chamois leather pad, but, in cases where the surface was rather rough and resisted the rouge, the polishing paste known as "Globe Polish" has given me good results. It is applied with soft cotton or cotton-wool. The objection to it is the greasiness, but this can be removed by polishing off with dry precipitated chalk. Instructive results can also be obtained, even more simply, on silver leaf laid down on glass plates coated with a clear crystal varnish. Specimens of results on all such plates are before you.

The first thing that strikes us in Daguerreotype is that the sensitive surface of the plate is formed by the direct combination of halogens, iodine, bromine, or chlorine, generally the first two, and sometimes all three together, with the metallic silver coating of the plate. The question arises, therefore, to which of these elements is the sensitiveness due? To the silver? to the halogens? or specially to the combinations? and how is it brought about?

#### SENSITIVENESS OF SILVER TO LIGHT.

I can find very little recorded about the sensitiveness of metallic silver to light beyond the fact that Moser found that silver, in common with most other metals, was sensitive to light. He exposed a silver plate for some hours in weak sunlight under a dark out-of-focus screen which was not in contact with it, and when the plate, which showed no change, had been allowed to cool, it was exposed to the vapour of mercury at about 170° Fahr. A clear image of the screen was produced, those parts where the light had acted had caused the deposition of a quantity of mercury. Plates of dark mirror glass and copper treated in the same manner showed the same result.

The series of phenomena which were dealt with in Moser's researches, especially those connected with the production of contact images, are, however, so peculiar in their results that it is still difficult to know to what cause they are really due. They have generally been attributed either to some impurity of the surface itself, to vapours given off by it, or to thin films of air or other substances in contact with it or otherwise affecting it. Robert Hunt was of opinion that many of Moser's effects were due to heat or thermic radiations.

In discussing the contact phenomena, the discovery of the sensitiveness of silver to light, as shown by the experiment described, has been overlooked, but I have been able to verify it, and, in addition, to obtain a visible printed-out image on the plain silver plate without any previous preparation—as you will see—also on silvered glass plates. In both cases the light seems to exercise a bleaching action, i.e., the exposed parts appear lighter than the unexposed and attract the vapour of mercury. By other experiments as to the electrical behaviour of silver partly exposed to light and partly unexposed, both in the dry state and immersed in water and other liquids, I have found that silver, though not very sensitive, does show undoubted sensitiveness, and it is also shown

by the change of colour of silver deposited on the cathode plate of a cell through which an electric current has been passed.

Carey Lea found that the three forms of allotropic silver he obtained, viz.:—A, the red soluble; B, the dark brown or blue insoluble variety; and C, the golden coloured, were acted on by light. A and B became brown after some hours' exposure, but with C the colour became lighter. This last result is similar to some of my own observations.

The oxides of silver are all sensitive to light and are decomposed by it. According to Hunt they lose oxygen by exposure, being first converted into a suboxide and then into metallic silver. In presence of organic matter the reduction is more complete.

#### HYDROGEN PEROXIDE A SENSITISER FOR SILVER.

I have also obtained some very interesting results with silvered glass plates fumed with peroxide of hydrogen before exposure, and find that it is capable of acting somewhat in the same way as iodine in sensitising the plate.

Mendeléeff remarks that the nearest approach to the properties of hydrogen peroxide is afforded by a non-metallic element—chlorine; its action on colouring matters, its capacity for oxidising and for evolving oxygen from many oxides is analogous to that exhibited by hydrogen peroxide. I do not know to what extent this similarity of hydrogen peroxide to chlorine extends to the other halogens, but the fact that there is such a relation, and that we find that hydrogen peroxide can act as a sensitiser to silver seems worth noting for further inquiry. I have here three plates, one sensitised by fuming with peroxide of hydrogen, another with chlorine, and the third with iodine; the results, after exposure to light and development with mercury, are practically the same on all three.

In the case of the Daguerreotype, as in other photographic processes with silver compounds, the sensitiveness of silver itself to light has hitherto not been regarded as in any way an essential factor in producing the results, which are usually attributed to the action of light upon the haloid compounds. It is, however, certainly of interest to know that it is sensitive, and even visibly so, and that images can be produced upon it by the action of light, which may be developed by condensation of mercury vapour, or by the precipitation of molecular silver with an ordinary acid iron and silver developing solution. As a matter of fact, nearly all the photographic phenomena, such as the development of an invisible image, the production of a visible image, reversal by over-exposure, and the effects of pressure in producing a developable image can be shown on the plain silver plate.

A further investigation into the nature of these images would be very interesting, and might show that the part played by the silver is a more important one than is usually assigned to it, and that this is the case seems to be shown by some of the results obtained in printing out on the iodised Daguerreotype plates.

#### PROPERTIES OF THE HALOGENS.

We now come to the halogens generally used in combination with silver. Though not very sensitive to light in the pure form, chlorine, iodine, and bromine are so when combined with other substances. They are all marked by their strong affinity for hydrogen, and to this is probably due the ready decomposition of substances containing them when exposed to light in presence of water or organic substances containing hydrogen. Compounds of chlorine are the most readily decomposed in presence of hydrogen, then those of bromine, and lastly those of iodine.

Chlorine may be combined directly with hydrogen under the action of light, but not iodine. Bromine and hydrogen combine under the influence of light at 196° C., and form hydrobromic acid. Watery solutions of chlorine and bromine are decomposed by light with formation of the corresponding hydrogen acids. A watery solution of iodine is not decomposed by light, but a solution in alcohol is so to a slight extent. The blue iodide of starch is distinctly sensitive to light.

The relation of the halogens to hydrogen is the reverse of their relations to oxygen, for which iodine has a much greater affinity than chlorine, while bromine occupies an intermediate position. In presence of water iodine can act as an oxidiser, but has very little bleaching power. Iodine, however, does not combine with oxygen under the influence of sunlight, either in presence or absence of water. There is no combination either between bromine and chlorine with oxygen in sunlight. It may be noted also that oxygen is not converted into ozone by the action of sunlight.

According to Mendeléeff (English translation, 5th edition, I. 465), under the influence of light chlorine is able to replace hydrogen by virtue of an action termed *metalepsis*, which is always accompanied by the formation of hydrochloric acid. In the dark chlorine does not usually act on hydrogen compounds, but the action commences under the influence of light. The direct action of the sun's rays is particularly propitious to it. It is also remarkable that the presence of traces of iodine added to the substance subjected to *metalepsis* often produces the same effect as sunlight. This action may be due to the formation of iodine chloride, which reacts more easily than chlorine. Bromine and iodine possess the same properties. Iodine itself, however, does not act by *metalepsis* on hydrocarbons on account of the easy decomposability of hydriodic acid, especially under the influence of light.

As not only their oxygen compounds, but also their hydrogen compounds, have acid properties, the halogens are elements of an exclusively acid character. This character is more strongly developed in them than in any other elements. This acid character of the halogens is very distinctly marked in all photographic processes.

Robert Hunt says of them (*Researches on Light*, p. 279): "Chlorine, iodine, and bromine, it is well known, act with considerable energy upon metallic bodies. If, however, any polished metal is exposed to the action of them in a diluted state, the combination is at first exceedingly small, and the films that are formed by either of these three elementary bodies upon any metal undergo considerable change under the influence of the sun. In most cases it appears that these bodies are set free, and the metal left in a state of very fine division or oxidation. Copper, tin, iron, zinc, lead, pewter, bismuth, and several other metals have afforded the same results. It is still more remarkable that films of bromine or iodine on glass are found under the action of the sun to act in a similar manner."

#### COMBINATIONS OF HALOGENS WITH SILVER.

According to Mendeleeff, silver gives insoluble and exceedingly stable compounds with the halogens. They are obtained by double decomposition with great facility whenever a silver salt comes into contact with halogen salts. (As I lately showed, this combination takes place even with dry powdered salts.) The degree of affinity of silver for iodine is greater than that for chlorine or bromine, so that, when exposed to light, the iodide does not part with its iodine as the chloride and bromide do with a portion of their chlorine and bromine.

Beketoff has explained the fact that silver iodide is more stable than the chloride or oxide by an original hypothesis—that the most stable compounds are those in which the weights of the combined substances are equal. Thus silver oxide is less stable than the chloride, and the iodide is the most stable.

Silver iodide is also more stable in respect to the action of light than silver chloride. Silver chloride quickly darkens, and appears to be decomposed into chlorine and silver. Silver bromide and iodide are much more slowly acted on by light, and, according to certain observations, when pure they are quite unacted on—at least, they do not change in weight; so that, if they are acted on by light, the change they undergo must be one of a change in structure of their parts, and not of decomposition, as it is in silver chloride. Silver iodide in presence of a large excess of silver, as in the Daguerreotype plate, darkens as readily as the chloride does when exposed with excess of silver nitrate.

As a combination of silver with iodine vapour forms the basis of the sensitive surface of the Daguerreotype plate, we may first of all consider it.

#### SILVER IODIDE.

Silver iodide is usually formed by precipitation from mixtures of solutions of silver nitrate and potassium or other metallic iodide. According as the silver or iodine is in excess, it has either a full yellow colour and is slightly darkened by light, or a very pale yellow colour, almost white, and is scarcely changed in colour by light.

We are, however, more interested in the comparatively little known forms of anhydrous iodide produced by the direct union of silver and iodine, and generally in immediate contact with metallic silver.

Before proceeding to consider the composition and behaviour under the influence of light of the sensitive surface of silver iodide on the Daguerreotype plate, it may be as well to examine the action of iodine upon silver in a very fine state of division. This can be readily done by adding iodine in various proportions to precipitated silver, and the resulting mixtures are more easily tested with various reagents than can be done on a plate.

Unless the iodine is in a very small proportion compared with the silver powder, the two may combine with a sudden rise of temperature and flame, the iodine vapourising and going off in violet fumes. The iodine must therefore be added only a little at a time, and be kept constantly stirred. In this way the full quantity required to produce the iodide, AgI, may be added.

Mixing precipitated silver thus with iodine in different proportions, such as 108 parts by weight of silver to 12.7, 37.1, 63.5, 95.2, and 127 parts by weight of iodine, we obtain a series of powders varying in colour from a grey or chocolate brown to an olive yellow, and finally brick-red tint. This last was shown by the preparation containing 108 parts of silver to 127 of iodine. It still contained a quantity of uncombined iodine as well as some uncombined silver inside the grains, but, if left in the air for a short time the excess of iodine evaporated and the powder turned to a deep orange yellow.

All the lower compounds are readily blackened by light, but the higher ones, with 63.5 parts of iodine (subiodide, Ag<sub>2</sub>I, (?) and upwards, are not so visibly blackened, and with the full quantity of silver and iodine to form the iodide (AgI) the mixture does not blacken at all in the light, just in the same way as the ordinary yellow iodide prepared by precipitation is not blackened.

This shows that the darkening is a function of the silver, increasing with the excess of silver and diminishing or entirely disappearing with excess of iodine.

If, however, we add precipitated silver to iodine, the yellow iodide is not formed at all, even when the full combining proportion of silver is added. This seems to be due to the iodine forming a coating on the silver grains which stops further action. The resulting compound is of a dark brown

colour with no grains of yellow iodide, as is the case when the iodine is added to excess of silver. By leaving the brown mixture till the excess of iodine has gone we obtain the same brick-red compound, which becomes yellowish on further exposure to the air. If more silver be added to take up the excess of iodine, the lower compounds are formed. I have not been able to very closely examine these curious compounds or mixtures of silver and iodine, but they seem worth further investigation.

There is one curious fact connected with the darkening of these mixtures or lower iodides which has already been noted, and that is that there is no loss of weight after exposure to light. Iodine is not set free, as is the case with chlorine or bromine, and it is difficult to know what the action really is, and whether there is any chemical decomposition by catalysis or otherwise, or whether the change is only structural. Recent researches by H. Scholl, to which attention will be drawn further on, seem to throw considerable light upon this question.

#### COMPOSITION OF THE SENSITIVE SURFACE OF THE DAGUERRETYPE PLATE.

That the sensitive surface of the Daguerreotype plate is formed by one of these lower compounds of silver and iodine, and not of the pure iodide, AgI, is, I think, shown by the fact that, if we iodise a thin film of silver leaf or silver on glass till all the silver has combined with iodine, we obtain an almost transparent pale yellow film, which no longer darkens very visibly even in bright sunshine, and is very insensitive, requiring long exposures to produce even the developable image. If, however, we expose a fairly thick plate of silver for several hours to the fumes of iodine, this yellow iodide is not formed at all, and we have instead a dark brownish or olive-coloured deposit, which is readily darkened by light, just as the iodised silver mixtures were, and as the Daguerreotype plate is. Some of this darkened deposit, treated with potassium iodide partly dissolved, the remainder still retaining its blackness; the addition of distilled water turned it yellow, the further addition of KI further dissolved it, but still left a dark purplish precipitate, which, being treated with nitric acid, behaved exactly like the original unexposed deposit, evolving iodine. HCl gave no precipitate of silver chloride, and therefore free metallic silver could not have been present.

Hence the surface of the Daguerreotype plate may be looked upon as iodised silver, or a compound containing a very small proportion of iodine in more or less loose combination with a large excess of silver. On exposure to light no iodine is set free or lost, but compounds are formed at the surface containing a larger proportion of silver, and therefore darkening more readily up to a certain limit, while the iodine penetrates more deeply, and attacks the underlying silver surfaces. That this is the case is shown by the fact reported by Moser, and also by Robert Hunt, that the darkened surface of an exposed Daguerreotype plate may be removed several times over, and still the under surface will remain sensitive. I have myself done this fifteen times over without exhausting the iodine or entirely destroying the printed-out image first impressed on the plate, and it was very remarkable how this original image came up apart from the ground after each exposure, which was taken up to solarisation point or beyond.

If, however, the proportion of silver to iodine is normal or in defect, and we have the anhydrous yellow iodide or orange super-iodide formed, we find that it does not darken in light, or only becomes a deeper yellow. A sample of pure yellow iodide, which was obtained from a well-known firm, shows this effect very distinctly on exposure to strong sunlight, but it loses this deeper colour again in the dark, becoming once more a pale lemon yellow.

Professor Meldola has suggested that the silver iodide on the Daguerreotype plate forms its own sensitiser, and from what I have seen of the deepening in colour of the above samples of iodide and others under the influence of light, or when treated with an excess of iodine, I have little doubt that this is the case. As we shall see later on, iodine may even exert an active sensitising action upon pure silver iodide.

#### TALBOT'S IODINE RINGS.

One of the most striking points with regard to the action of iodine on a polished silver plate is the series of interference colours it produces, in accordance with the thickness or varying composition of the film of iodide produced, and I cannot do better than show you an old experiment which was first tried by Fox Talbot, and described in the *Athenæum* for 1839, p. 643, also in Hunt's *Researches on Light*, p. 102. If we place a small crystal of iodine on a polished silver plate or a silvered glass, and warm it gently with a spirit lamp, we shall at once see a series of about seven sets of concentric rings, forming prismatic or interference colours exactly similar to those of Newton's rings, or rather Nobili's rings, which are Newton's rings reversed. First, outside we have a bright yellow, and within this there arise successively rings of green, red, and blue, and then again a fine yellow circle, centered by a greyish spot on the place occupied by the iodine. Now, if we cover up one-half of the series of coloured rings and take the plate into the sunshine, we shall see one of the most striking and beautiful exemplifications of the action of light it is possible to conceive. The rings are sensitive to light, their colours change and become intensified, producing quite a new series of rich prismatic tints, which completely illustrate and prove the fact I have just drawn your attention to, that darkening increases in proportion to the excess of silver, and lessens with the increase of iodine. The outer circle, which before exposure was only a pale rose colour (the most sensitive iodide colour), is now a deep brilliant green shading into a

strong reddish-violet, and then into beautiful dark blue, succeeded by a broad white or very pale green merging into a deep yellow, succeeded by a series of fine well-marked concentric rings of much the same tint as the original unexposed rings, but deeper and brighter. The tints vary somewhat according to the length of exposure. The outer rings produced by the thinnest stratum of iodised silver, furthest from the centre, must be in a very loose state of chemical aggregation. Talbot says the coloured rings seem to consist of silver iodide in various stages of development. If we turn the plates downwards at an angle of 45° to the light, we shall see that the colours are reversed and show complementary tints.

There is another method, due, I believe, to Wiener, by which these colours can be shown, and almost more brilliantly, by resting the plate on a glass cylinder while being iodised. This produces a double set of coloured bands, one on each side of the central blank space, as you will see. Viewed by reflected light, the complementary colours are very rich and almost fluorescent in their luminous intensity.

These gorgeous tints do not, however, represent any distinct chemical change in the composition of the sensitive surface beyond the production of films of iodised silver of varying thickness; and, if after exposure to light we submit the plate to the fumes of mercury vapour, or treat it with an acid iron and silver developer, we shall get no distinct image of the series of rings, but only two or three bands or regions of increased or diminished sensitiveness. With short exposures these bands are fairly distinct, as you will see from the example I have with me. The same result is obtained with images simply fixed with hyposulphite of soda. The outermost rings show an increase of action which is succeeded in the broad bluish or greenish-white band by a decrease, the action increasing again towards the central series of rings. The behaviour of these coloured rings under coloured glasses will be noticed further on.

#### RELATIVE SENSITIVENESS OF TINTS PRODUCED BY IODISING.

The relative sensitiveness of the various tints produced on the surface of a Daguerreotype plate by the vapour of iodine was first studied by Professor J. W. Draper, of New York, and his results are recorded in a paper published in the *L.D.E. Phil. Mag.* for September, 1841. He found that the plate passed through the following stages of colour:—

1, lemon yellow; 2, golden yellow; 3, reddish yellow; 4, blue; 5, lavender; 6, metallic; 7, yellow; 8, reddish; 9, green, &c., the differences of colour being produced by the differences of thickness in the film of iodide, and not by any difference of chemical composition.

Talbot's rings show this fairly clearly. The outer rings are coloured much as stated by Draper, then comes the strong second yellow, followed by red and green, and, as the iodine acts longer and produces a thicker film, the rings become closer and darker as well as less sensitive to light. I find, however, that they attract mercury vapour readily, after exposure.

Having prepared nine plates showing the different tints above indicated, Draper exposed them under uniform conditions to the light of a gas flame, and found that No. 1 showed a well-marked action; No. 2, still stronger; but that the rays had less and less influence down to No. 6 (metallic), in which they appeared to be almost without action: but, in No. 7 (second yellow), they had recovered their original power, being as energetic as in No. 2; and from that they declined again.

Hence, as Draper says, we see that the sensitiveness of the iodide of silver is by no means constant; that it observes periodical changes, depending on the optical qualities of the film, and not on its optical composition; that by bringing the iodide into those circumstances that it reflects the blue rays, we greatly reduce its sensitiveness, and still more so when we adjust its thickness so as to give it a grey, metallic aspect; but the moment we go beyond this and restore by an increased thickness its original yellow colour, we restore also its sensitiveness.

Upon this and other observations, Draper, so early as 1841, laid down, among others, two important propositions upon which all photographic action is based:—

"That the chemical action produced by the rays of light depends upon the absorption of those rays by sensitive bodies, just as an increase of temperature is produced by the absorption of those of heat.

"That the sensitiveness of any given substance depends on its chemical nature and optical qualities conjointly, and that it is possible to exalt or diminish the sensitiveness of any chemical compound by changing the character of its optical relations."

The first of these propositions has been termed by Professor Meldola *Draper's law*.

The practical application and extension of this principle led the late Dr. H. W. Vogel to the discovery of the modern system of orthochromatic photography, and by applying suitable dyes, or, as he called them, *optical sensitizers*, to the ordinary photographic dry plates, he found that they could be rendered sensitive to the rays at the less refrangible end of the spectrum for which they are ordinarily insensitive. I cannot, at present, go further into this question, but it is important to note that this most important discovery was based to some extent upon Draper's observations of the different degrees of sensitiveness produced on Daguerreotype plates, according as the colour of the sensitive surface of silver iodide affected its absorption of the rays of light.

#### DEVELOPING ACTION OF RED AND YELLOW LIGHT.

One of the most curious and remarkable phenomena connected with

the early working of Daguerreotype plates is the action of red or yellow light upon the images formed either in the camera or by printing out. Thus, if we give a short normal exposure to an iodised silver plate, and instead of developing it in the ordinary way by the vapour of mercury or by treating it with an acid, iron, and silver developer, we expose it in the sun under a red glass from fifteen to twenty minutes, we shall find to our astonishment a completely printed-out image, containing quite as much, if not more, detail than would have been shown by the deposited mercury or silver, while the protected parts originally unaffected by the light, remain perfectly unchanged, and, on fixing with hyposulphite of soda, retain all their original brilliancy and clearness, as you will see. The curious thing is that the iodised silver coating shows itself quite insensitive to the action of light passing through the same red glass which, after even the faintest action of white light has affected the sensitive surface, will continue the action and carry it to full intensity, and even on to bronzing or solarisation.

This phenomenon seems to have been first discovered by Ed. Becquerel when working with the spectrum. He found that if an iodised silver plate were exposed to the spectrum it was not sensitive beyond a point more than half way between c and f; but if the plate had previously received a short exposure to light, it was then sensitive to the whole length of the spectrum up to r, and from this point to beyond a there were signs of reversal or destruction of the image. Becquerel, therefore, called the rays at the most refrangible end of the spectrum the *rayons excitateurs*, while those at the less refrangible end he called *rayons continuatateurs*.

Shortly afterwards Gaudin succeeded in developing an image as perfect as that produced by mercury by submitting the plate when taken from the camera to the action of light under a yellow glass and without any subsequent exposure to mercury.

Claudet, Hunt, and others also investigated this curious phenomenon, and a good many explanations were put forward regarding it, but the one given by Bunsen and Roscoe in their paper "On the Phenomena of Photo-chemical Induction," in the *Phil. Trans. Roy. Soc.*, 1859, p. 400, whether correct or not is interesting in other respects. As it is not generally known, it may be worth quoting from the original, because it seems to have a distinct and important bearing upon other obscure phenomena connected with the formation of the invisible developable image on photographic plates of all kinds.

#### PHOTO-CHEMICAL INDUCTION.

By photo-chemical induction the authors mean the act by which the resistance to chemical combination of different bodies is diminished by the active agency of light.

"The laws of photo-chemical induction which we have here developed, explain most completely many of the singular phenomena which lie at the foundation of the photographic processes. Without entering into detail concerning the relations which these laws bear to the general processes of the photographer, we will now merely consider one phenomenon which has been so difficult to explain, that it has been found necessary to assume the existence of certain rays endowed with very peculiar properties, to which the name of *rayons continuatateurs* has been given. This phenomenon was first established by Edmond Becquerel from the following observations. If one-half of an iodised plate of silver or a sensitive photographic paper be protected from the action of light whilst the other half is exposed to a constant source of light for such a time that no alteration, either perceptible to the eye or capable of being developed by photographic preparations, is effected on the sensitive surface, the plate possesses the property, when exposed to a uniform but very slight amount of light, to blacken on the insulated half, whilst the part not previously exposed remains unaffected. If, in the first short insolation, every part of the plate was not exposed to the same intensity of light, the blackening effected by the following uniform exposure corresponds to this intensity, so accurately, indeed, that a Daguerreotype picture commenced by this slight exposure may be developed by subsequent uniform insolation, almost as perfectly as if each amount of light represented on the picture, and not a constant amount, had acted for the whole time upon the plate. The explanation of this fact does not require the assumption of a new class of rays, which cannot commence, but only continue, the photo-chemical action. The phenomenon is in reality a simple consequence of the laws of photo-chemical induction, and proves that these relations, which we have examined only in the case of chlorine and hydrogen, occur in a slightly modified form in other photo-chemical processes. If the chlorine and hydrogen mixture were a solid substance which could be fixed upon paper without diminishing its sensibility to light, this paper must exhibit exactly the same singular property which Becquerel first observed with the Daguerreotype plate, or other photo-chemically sensitive surface."

They then prove this by examples taken from their actual experiments.

In the first case, if it takes, say, five minutes before any chemical decomposition of the sensitive surface is effected, and a plate has one-half protected from light and the other half exposed for five minutes, although both parts show no visible action, the exposed half has five minutes' start, and if the whole plate be now exposed to uniform insolation, the half previously exposed will act quite differently from the half which remained in the dark.

The exposed half begins darkening at once, gaining intensity every

minute, while the unexposed half must remain for five minutes before any darkening action can take place.

The second case is similar. An image commenced by lights of various degrees of intensity is developed by a subsequent uniform exposure in depths of colouring proportional to the original varying intensities. The same thing happens if "the sensibility of the plate is altered by the first exposure to light, and in such a manner that the greater luminous intensity corresponds to the greatest sensibility. If the varying amounts of sensibility which the surface of the plate has reached by the first exposure could be represented by depths of colouring, the various shades would represent the picture itself. With a subsequent uniform insolation, the chemical action must therefore proceed proportionally to the various amounts of light in the original picture, and, if the chemical action is made visible by a change of colour, an actual picture must be produced."

Dr. Vogel has explained this phenomenon, in a very simple manner, by the supposition that during the preliminary exposure a sub-salt is formed which changes the absorptive properties of the surface and renders it sensitive to red and yellow rays.

Iodised silver plates show this phenomenon quite distinctly with deep red, yellow, or cathedral green glasses. For instance, a plate had two exposures under a graduated screen: first, a short one showing no visible image; the second, printed out to show up to 3 or 4 of the scale of 7 gradations. After some twenty minutes' exposure under the red glass, the first exposure showed a clear printed-out image up to 3 or 4 of the scale, similar to that produced by the second printed-out exposure, while this last image was fully printed out and extended under the influence of the red glass up to 7, or the full extent of the scale, the original numbers 0 to 3 being strongly bronzed, just as they would have been by a longer exposure to white light. They had, apparently, been iodised.

In the same way, an iodised silver plate exposed in white light under a scale of fifteen coloured glasses, and only showing visible action under the blue and lavender glasses, when further exposed under a red glass, showed action under all the blues and violets and bluish-greens, but not under the reds, yellows, and yellowish-greens at all, though this developing action was going on under a red glass.

Yellow and green glasses gave much the same effect. Violet glasses, either reddish or bluish in tint, did not answer at all—nor did blue glasses—the images already formed seemed to grow weaker instead of stronger, and they were removed entirely in fixing, leaving no trace.

The developing action of the red, orange, yellow, and green glasses may also be shown upon silver surfaces which have been treated with iodine, so as to show Talbot's rings, and, although there are no very marked changes in the chromatic relations of the different series of rings, there are changes which might repay further investigation. I have brought with me a series of plates illustrating the changes produced in these rings by exposure to white light, as well as to coloured light passing through glasses of various colours.

Under a red glass there is little perceptible change in the inner series of rings, but in the outer rings the blue, violet, purple, and red are almost absent, and their places taken by shades of mauve and dull green. The rings that were entirely unexposed show no change.

Under the orange glass the effect of the glass on the series of exposed rings is very similar to that produced by the red glass, but there is also a considerable developing action shown on the unexposed rings, and the scale of colouring is quite different to that shown by the exposure to white light. In the latter the outer rings are marked by a deep pansy-like bluish-purple fringed with green, while in the outer rings exposed under orange glass we have a fine, pure blue, fringed with purple, and shading out into brown.

The action of the yellow glass is similar to the orange; but, as the original exposure under white light was not carried to the green or solarisation stage, the contrast between that set of rings and those exposed under the yellow glass is not so marked, though there is a very distinct difference.

The effect of the cathedral green glass is very marked, especially in the outer rings, which show grades of pale mauve, blue, violet, and a rich bright green in the part originally exposed to white light, while the unexposed rings, though showing a considerable extension of action under the glass, are very similar to those exposed in white light, but show less red.

The blue glass shows a very marked effect, quite different to the glasses noted above. The exposed and unexposed series show practically the same effect under the blue glass, while the scale of colouring is markedly bluer, the outer rings being shown by shades of lavender or mauve working into blue-violet, and then into shades of rich blue-green, followed by a yellow-green, and then pink.

Efforts have, I believe, constantly been made to utilise this principle of after-exposure under a red glass in practical photographic work, especially in taking astronomical photographs, but the trouble is that it works best with rather insensitive plates or papers, and so there is not much saving of time. However, it might be of use in cases where large numbers of prints had to be produced from a single negative, and it would be an object to shorten the exposure required under the negative. The point to observe is that the first exposure must be sufficient to start the action in the under-exposed parts, and that the sensitive surface

must be almost insensitive to the rays coming through the coloured glass. The ordinary P.O.P. paper shows the effect well.

The fact fully brought out by Bunsen and Roscoe's researches on photo-chemical induction, but first observed by Draper, that the action of light upon a mixture of chlorine and hydrogen does not take place instantaneously, but that a considerable continuation of the exposure is necessary before an action occurs, has, I think, an important bearing upon the much-vexed question of the physical or chemical nature of the latent developable image on photographic plates.

Bunsen and Roscoe found that, if the chemical rays emanating from a constant source of light be allowed to fall upon a mixture of chlorine and hydrogen which has stood for some time in the dark, no appreciable quantity of hydrochloric acid is formed during the first few moments. After some time has elapsed, a small action is observed which very gradually increases, until after a considerable space of time a permanently constant maximum is obtained. The time which elapses from the first insolation until the first traces of the photo-chemical induction become visible, and until the maximum action is attained, is, according to circumstances, extremely different.

Bunsen and Roscoe also pointed out that in their experiments they had to do with the purest form of the phenomena which are classed under the name of catalysis, freed from all foreign disturbing causes.

These researches on the action of light upon a mixture of chlorine and hydrogen have been continued by Pringsheim (*Wied. Ann. Phys. u. Chem.*, N.S. 32, 1897), who found that photo-chemical induction is not dependent upon the colour of the light, but only upon its chemical intensity; and it seems probable that the photo-chemical induction is based upon chemical processes connected with the formation of hydrochloric acid gas, and not upon any peculiarity in the action of light. He found also that the first visible action of light upon the gaseous mixture of hydrogen and chlorine consisted in an abruptly increasing and an equally abruptly decreasing of the volume of the gas, the amount of which was proportional to the intensity of the light producing the action. This sudden increase in the volume is brought about by a momentary dissociation of the molecules which takes place at the moment of the chemical change. Scarcely any hydrochloric acid is formed, but rather an intermediate substance. The slow formation of this acid only takes place when the mixture of gases is moist; dry gas is not sensitive except in strong light. The intermediate product which produces photo-chemical induction, and the assumption of which is completely explained by this phenomenon, arises probably from the decomposition of watery vapour. This last observation seems to have considerable importance, as Nernst has shown.

I do not know whether any series of experiments have yet been made on the basis of these researches of Bunsen, and Roscoe, and Pringsheim with photographic plates. We know now that hydrogen is not a metal, as was at one time supposed, and therefore its relations with halogens might not be exactly comparable with those of silver and other metals forming light-sensitive compounds; but, from results I have obtained during the course of experiments with iodised silver plates, I believe that a carefully carried-out series of observations upon the action of light on plain silver surfaces, in combination with the halogens and mixtures of them, might yield very valuable information as to the mechanism of the latent developable image, and throw more light upon the composition of the products of reduction, which, though small in quantity, are in a form more easily amenable to chemical analysis than is the case with ordinary photographic plates prepared with collodion or gelatine.

Quite recently Dr. R. Luther has shown that, when silver is acted upon by small proportions of chlorine water added in stages, the oxidation potential, as shown by an electrometer, remained at first constant at 0.55 volt, but suddenly sprang to 1.45 volts as soon as half the silver had been combined with the chlorine corresponding to the sub-chloride  $\text{Ag}_2\text{Cl}$ . It then remained fairly constant at 1.45 volts until the whole of the silver had been converted into chloride. This action seems somewhat analogous to Pringsheim's observation of the sudden rise at the moment of chemical change between hydrogen and chlorine. Many of Bunsen and Roscoe's observations show similar sudden rises and gradual increase to a maximum.

It seems not unlikely, therefore, that for a certain time, which is variable, according to the nature of the sensitive surface and the intensity and character of the light, the action of light is physical or mechanical, and that the latent developable image is not formed till the moment when chemical decomposition begins and the stage of under-exposure is reached; a certain further period of action produces the stage of chemical decomposition, corresponding to normal exposure, and still further we reach the stages of the visible image, over-exposure and solarisation, which in some cases appears to be equivalent to electrical polarisation and reversal.

#### ACTION OF LIGHT UPON PURE SILVER IODIDE.

We now come to the question of the action of light upon a surface composed of pure silver iodide, such as may be obtained by completely converting the thin silver film of a silvered glass into iodide.

If we expose a piece of silvered glass to the fumes of iodine for about an hour and a half to two hours, till the silver coating is entirely converted into the anhydrous iodide, we obtain on almost transparent pale greenish-yellow film. According to some writers, this film of pur

iodide is absolutely insensitive to light, either visibly or by development. I have not found it so. Visible images may be obtained by exposure in daylight, or even in the camera.

As there is no active iodine absorbent present in the film, either free silver or its compounds or organic matter, the action of light on these plates would appear to be more of a physical or mechanical nature than chemical, though, as we shall see later on, there is a very strong probability that chemical actions play their part in a somewhat obscure way.

One of these plates was exposed in the camera for seventy-five minutes upon a view of sky and houses. There was no distinct visible image, but mercury vapour brought out a faint outline of the tops of the houses against the sky, the sky being darker than the houses, &c. There were no details. The plate was left in the mercury box in the hope of bringing up more, but the image gradually disappeared, and eventually did so completely, leaving absolutely no trace. The same thing happened, though not so completely, on another plate exposed in the same way, but showing a distinct visible image after exposure in the camera, and also developed with mercury. A similar vanishing of a developed image was also noticed on one of the silvered glass plates, which was exposed for some days from the glass side. There was no visible image on that side, but there was an image on the unexposed face of the glass, which could be brought out by breathing. On developing the plate with acid iron and silver, and forcing it a little, traces of the image were distinctly visible from the glass side of the film; but, after the film dried, all traces of the image had disappeared from that side as well as from the front. From these two instances there seems to be some ground for believing that photographic images may be produced by purely molecular action.

On exposing another of these super-iodised plates for five minutes in the sun under a screen of fifteen coloured glasses, I noticed that where the light acted through the blue, violet, and bluish-green glasses, the film appeared more or less opaque and clouded, whilst the edges of the plate, which were freely exposed to the sun the whole time, were only very slightly darkened or different to the unexposed ground. On developing with mercury the vapour was deposited on all the affected spaces under the coloured glasses, but not on the protected parts or the unaffected spaces under the red, yellow, and green glasses, nor on the over-exposed and solarised parts outside. Development with acid iron and silver gave precisely similar results, as you will see from these two plates. The images in both cases are rather thin.

This peculiar turbidity or opacity of the fully iodised silver film when exposed to light was noticed by Schultz-Sellac (*Photo. Mitth.*, 1871, p. 60; or *Photo News*, 1871, p. 308). He says that the action of light is sometimes shown by the production of a series of colours in the film when viewed by transmitted light, by refraction of the light through the particles of iodide of silver. I have not noticed these variations of colour.

He further says: "If different parts of a plate are exposed to the action of light for various periods, covering portions partially with an opaque shield, which is drawn away after certain fixed periods of time, it will be observed that the action is apparent only after the lapse of a certain time, and it suddenly increases with great rapidity. To start the action in the first instance, therefore, a certain amount of light is necessary." This, it seems to me, furnishes a practical corroboration of Bunsen and Roscoe's theory of photo-chemical induction, and may be compared also with Luther's recent observations, previously referred to.

According to Schultz-Sellac, the presence of a small quantity of free iodine is necessary to the occurrence of the mechanical change; by keeping some time in the air or by treatment with iodine absorbents, the sensitiveness of the material to mechanical change is annulled, but again restored by further fumigation with iodine. In my own experience I have not noticed any very marked difference of action between plates that have been left in the air before use or fresh ones still charged with iodine, though the latter are, I agree, more sensitive, i.e., more quickly affected by light than the former. If a plate has, however, been exposed to light in contact with an iodine absorbent—silver, copper, or tannin—then, although there is a decided darkening visible by transmitted light, the film does not become opaque.

If, again, as suggested by Schultz-Sellac, one of these over-iodised plates is partly coated with collodion or varnish, then we notice a very marked difference between the images produced on the varnished and unvarnished parts. This is very clearly shown in the prints of a graduated scale I have here. On the unvarnished half we have a strong series of pale whitish-yellow bands decreasing very distinctly in density, while on the varnished half, though exposed longer, the images of the bands, though visible, are all more or less phantoms. It must be noted, however, that the varnish is a strong iodine absorbent, which collodion might not be.

Schultz-Sellac found that somewhat similar effects could be produced with films of pure iodide of silver in collodion fumed with iodine. He attributes the changes of colour which are observed to a mechanical change in the particles, and not a chemical change.

In a paper published last June in *Wiedemann's Annalen*, H. Scholl has very fully investigated the changes produced by the action of light on silver iodide and Daguerreotype plates. In the third section he gives the results of his inquiries into the cause of this peculiar turbidity. He first shows that, as we have already seen, if the film of pure silver iodide pro-

duced as described is covered over by a coating of varnish, collodion, or some other suitable substance, the cloudiness is produced very much more slowly. This may be due either to the coating preventing the escape of iodine or the access of air. If any iodine is given off during exposure, we ought to be able to detect it by placing the iodised film in contact with a plain silvered glass surface. On doing this he found that there was some change on the silvered surface, but not more than could be observed by exposing the silver to a light of the same intensity, but not in presence of the silver iodide. There were no distinct interference colours, and he does not consider the experiment convincing.

I have tried this experiment several times in different ways, and find that the plain silver surface is very distinctly and even visibly affected by contact with the iodised plate during exposure, and certainly very much more so than if exposed by itself under the same circumstances. For instance, a slip of pure silver foil was exposed for fifteen minutes in the sun under one of these iodised silvered glass films, but separated from it by a cut-out screen of mica. The silver foil showed distinct images of the cut-out designs, which darkened still further when exposed to light, and were quite soluble in a solution of potassium iodide. The parts of the foil protected by the mica were quite unaffected. Similar results were obtained with polished copper and with paper soaked in tannin, the images in the latter case being brought out with weak aceto-nitrate of silver.

MAJOR-GENERAL J. WATERHOUSE, I.S.C.,

Hon. Secretary, Royal Photographic Society.

(To be continued.)

#### THE HACKNEY PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE Hackney Photographic Society held its Tenth Annual Exhibition at the Morley Hall, Hackney, on the 15th, 16th, and 17th inst.

In reviewing the successive Exhibitions of the Hackney Photographic Society, it has always been our pleasing duty to record an improvement in the work of the members. Last year we commented upon the comparative absence of photographs which bore the impress of being the beginners' early attempts, and the consequent higher average quality of the pictures as a whole; but, while progressing at more than the usual rate, the improvement was more marked in the work of the junior members than in that of the seniors. This year a distinct advance all along the line was evident. The strength of the Hackney Society has been hitherto in landscape work, and naturally, perhaps, the features of their most easily reached hunting ground, the flat districts of their adjoining county, seem to have had a great influence in the choice of subjects; but, however excellent the pictures may be individually, too much of any class of subject is apt to be depressing. We welcome, therefore, the greater variety which we found at the present Exhibition, both in the subjects and in the treatment of them. Until this year it would have been unkind to compare the work in the members' classes as a whole with that in the open classes, but now the Society need not fear the result of the comparison. It must be admitted, however, that the work in the open classes was not quite as interesting as usual. In architectural work the members have made wonderful strides during the year, or at least some of them have, for the class was not a large one. The portraiture and figure studies showed improvement, but not to the same extent. We regretted to find that the separate class for hand-camera work was retained. There may be something to be said in favour of dividing an Exhibition into classes according to subjects; but in these days, when a large proportion of all Exhibition work is from hand-camera negatives, there is no reason whatever why hand-camera work should be treated in any other way than according to the merit of the pictures themselves. It would perhaps be reasonable to have a class for subjects which include objects in motion, but at this Exhibition, and in the corresponding classes at other Exhibitions, we almost invariably find that the majority of the negatives might have had quite a prolonged exposure as far as the subjects are concerned.

It is satisfactory to note that the enthusiasm of the members shows no signs of falling off. The entries were over fifty in excess of last year's Exhibition, and the number of exhibitors had increased by eleven. The average size of the pictures was considerably larger. The open classes showed a slightly decreased number of frames. The arrangements of the Exhibition were carried out in the complete way the Hackney Society always carries out its functions. In addition to the usual attractions of an Exhibition concerts were arranged for each evening, and lantern entertainments were given in the small hall.

The Judges were Messrs. A. Horsley Hinton, Harold Baker, and J. B. B. Wellington. We understand the last-named gentleman did not act.

As we have mentioned, the Members' Class for Portraiture, Figure, and Animal Studies showed an improvement, but, at the same time, it was not so strong a class as we think the Hackney Society ought to be represented by, either in quantity or quality. Twenty-seven frames out of the 223 which constitute the members' collective exhibit is certainly an inadequate proportion for all the kinds of subject which are included in the section. Although even the tail end did not descend to the depths which a portrait or figure study is capable of, there was very little evidence of any serious

attempt to treat the subjects in any other than a hap-hazard way. Dr. Roland Smith's *Mother's Firing*, for which he received the silver medal, was quite obviously a boy with a bundle of sticks, standing to be photographed, and the composition was not quite happy. The print was otherwise good, and it struck us that this was the case of a capable photographer undertaking a subject of which he understood neither the possibilities nor the limitations. The portraits, though not showing the quite worst faults of photographic portraits, did not rise above mediocrity. The animal studies, as represented by snap-shots in the Zoo, were quite ordinary, with the exception of W. Selfe's *Lions*, which was admirably treated. A landscape with sheep, by W. L. Barker, was a good attempt; its principal faults were clearly due to under-exposure in the original negative.

The principal exhibitors in the Architectural Class were Dr. Roland Smith and W. Rawlings, nearly one half the pictures in the class being by them, and their collective exhibit would have constituted quite a good class in itself. All the good things, however, must not be attributed to them. G. U. Haslam's work was distinctly creditable, and we can only surmise that W. A. Ellington's exterior of Christ's Hospital was too much unlike the usual thing to please the Judges, for it certainly deserved some recognition, if only for the originality of its treatment.

The Landscape Class was, as usual, by far the largest one, about one half the frames in the members' classes being here shown. There could hardly be any difference of opinion as to the merit of Mr. W. A. I. Hensler's *Stormy Sunset*, which received the silver medal of the class, and the gold medal for the best picture in the members' classes. Mr. Hensler's work has always been good, but he has undoubtedly progressed by leaps and bounds during the past two years. He has attempted more varied subjects, and has greatly increased his knowledge of how to treat them. In losing what had amounted to a maximum, his pictures have naturally become more interesting, especially as he is a very prolific artist. Mr. W. Rawling's work was of its usual refined character, and better, on the whole, than any we have seen previously. Mr. W. Selfe has also made good progress, and his work was an improvement on that of last year, but this we might go on saying until we had almost exhausted the list of the usual exhibitors. Among those to whom this applies are Messrs. F. E. Roofs, W. L. Barker, G. U. Haslam, S. C. Stean, J. J. Westcott, F. W. Gosling, J. Gardner, W. Fenton-Jones, J. O. Grant, and Dr. Roland Smith. Mr. H. W. Lane, whose work we do not remember to have seen before, has had the good fortune to receive the bronze medal in the class.

The Hand-camera Class certainly showed a great improvement on the work usually found in such a class. In many, perhaps most, cases the pictures were enlargements from the original negatives, and, as we have said, quite a large proportion did not suggest any necessity for the use of a shutter for exposure. The bronze medal picture, for instance, was an interior, very nice in its way, but, as it must have had a time exposure, there is no obvious reason why it should be allowed to compete except in its own subject class. Some of the best pictures were contributed by Messrs. F. E. Roofs, W. Rawlings, H. W. Lane, W. Selfe, W. A. I. Hensler, W. Fenton-Jones, G. H. Copper, Dr. Roland Smith, and Mr. W. D. Welford.

The members' lantern slides were more than up to the usual standard. Indeed, we think they were better, on the whole, than those in the open classes.

The General Open Class we thought rather weak, especially in landscape subjects, and this was evidently the opinion of the Judges, for, of four awards (two medals and two certificates), two went to architectural subjects and one to flowers. The Portraiture Class was a better one; still, there was little that was striking. There was an absence of the fine bold work one usually finds here.

The Champion Class contained some fine work, but it maintained the general reputation of champion classes here and elsewhere for containing some of the worst photographs in the Exhibition.

The lantern slides were good on the whole, but the entries were not so numerous as at last year's Exhibition. In the Champion Class, one of the members of the Society, F. E. Roofs, took the bronze medal.

The class for stereoscopic transparencies and prints, though not a large one, contained some very good slides. Both prizes were taken by members of the Society.

Among the principal exhibitors in the Open Classes were J. M. Cooke, H. Quilter, H. C. Lest, J. M. Hoffmeister, H. W. Barnett, H. Lewis, J. Gunston, C. T. Humphrey, W. J. Croall, J. M. Whitehead, F. N. Fielder, J. Auld, S. C. Tyler, Viscount Maitland, R. B. Lodge, W. J. Byrne, C. Speight, C. Sweet, C. M. Wane, J. Leslie Shawcross, W. F. Slater, G. H. Capper, J. T. French, Graystone Bird, Edgar R. Bull, and F. E. Roofs.

There was a loan collection of pictures by J. Page Croft, Wilfrid Groom, J. Carpenter, and Harold Baker; and skiagrams by Dr. C. G. Burton.

The trade exhibitors were Messrs. Watson & Sons, Griffin & Sons, R. & J. Beek, Burroughes & Wellcome, Thorne & Hoddle, and the Tella Camera Company.

The following is the list of awards:—

#### MEMBERS' CLASSES.

Class A (Portraiture, Figures, and Animal Studies).—Silver medal, Dr. Roland Smith; bronze medal, Walter Selfe; certificate, Albert Boes.

Class B (Architecture).—Silver medal, Wm. Rawlings; bronze medal, Dr. Roland Smith; certificate, E. J. Hunt.

Class C (Landscape, Seascape, and Flower Scenery).—Silver medal, W. A. I. Hensler; bronze medal, H. W. Lane; certificates, W. Selfe and S. C. Stean.

Class D (Hand Camera Work).—Silver medal, F. E. Roofs; bronze medal, W. D. Welford; certificates, W. Selfe and W. A. I. Hensler.

Class E (Lantern Slides, set of four).—Silver medal, Dr. Roland Smith; bronze medal, W. Selfe; certificate, W. A. I. Hensler.

(Best Picture in Members' Classes).—Gold medal, W. A. I. Hensler.

#### OPEN CLASSES.

Class F (General).—Silver medal, C. H. Oakden; bronze medal, J. M. Whitehead; certificates, H. W. Bennett and Hugh Lewis.

Class G (Portraiture and Genre).—Gold medal, F. N. Fielder; silver medal, C. Sweet.

Class H (Champion).—Gold medal, J. Leslie Shawcross; silver medal, J. M. Whitehead.

Class I (Lantern Slides, sets of four).—Silver medal, R. B. Lodge; bronze medal, J. Gunston; certificate, Graystone Bird.

Class J (Lantern Slides, Champion sets of four).—Silver medal, E. R. Bull; bronze medal, F. E. Roofs.

Class K (Stereoscopic Prints and Transparencies, sets of four).—Silver medal, L. S. Wilks; bronze medal, A. D. Fort.

Silver medal for best trade exhibit.—W. Watson & Sons.

#### ENLARGING SIMPLIFIED.

In the course of a practical chat on "Enlarging," before the Members of the Borough Polytechnic Photographic Society, Mr. R. R. Rawkins described what he considered to be an ideal enlarging camera, and one which he had in use for a considerable time with highly satisfactory results. Its construction was extremely simple, and, although artificial light formed the illuminant, yet his method of working quite obviated the use of a condenser. The objective consisted of an ordinary bellows camera and lens, and the one by which the negative was produced answered all purposes. This was affixed before a suitable opening in a box containing the source of illumination. Personally, he used two incandescent burners, placed on either side of the opening, each having a semicircular reflector in order to prevent any direct rays from reaching the negative. The whole of the inside of the box was painted or papered white, and by this means the light was reflected back, and evenly distributed throughout the plate. Oil lamps could be used in a similar manner, and those with circular wicks were perhaps the most suitable. Whilst the simplicity and cheapness of this arrangement was obviously apparent, he claimed that it was the only reliable method by which enlargements could be made from negatives that had been "doctored" to any extent. This was impossible when using a condenser, as such "faking" would be amplified in the resulting enlargement. Again, it was superior to daylight, inasmuch as the light was always constant and under perfect control. He thought there was a good opening for some enterprising manufacturer to put on the market such an apparatus as he had described.

#### A NEW METHOD OF ARTIFICIAL LIGHTING FOR PORTRAITURE.

At the last meeting of the Croydon Camera Club, Mr. W. H. Smith gave a demonstration of "A New Method of Artificial Lighting for Portraiture."

Mr. Smith, at the outset of his remarks, alluded to a few of the methods of artificial lighting in use for photographic work. There were great disadvantages in the systems already adopted. The arc lamp had its drawbacks in its expense of current and skilled labour required to use it and also in its varying candle power. A certain system of incandescent lights seemed to have an insufficient reflecting surface, and was deficient in actinic rays. Incandescent gas was probably the worst of the lot, as it was found not very durable, the heat was unbearable, and the light far from satisfactory. Flash lamps were rather dangerous, and a nuisance also arose from the fumes and products of combustion. One of the great difficulties experienced with artificial light was the want of diffusion, and he had come to the conclusion that they might obtain what they wanted, viz., a pure reflected light, with magnesium burned in oxygen. With this end in view, he had fitted up a room lined with white paper to diffuse the light satisfactorily and evenly. Mr. Smith then proceeded to explain in detail the various experiments which had led to the present invention. This was a piece of magnesium ribbon, fired by a current of electricity in a glass combustion vessel containing oxygen, with the help of mechanism specially contrived for the purpose. The cost of this system of lighting was very small, the total outlay being about one farthing per exposure. He had arranged his apparatus so that just as much oxygen would be taken up as was needed for the exposure. About five inches of magnesium wire was used at one time, and the combustion vessel contained a little water to keep it clean.

With the assistance of Mr. A. Beales at the camera a number of negatives were taken by the new light of those present, and these, on being developed, showed most clearly the success and importance of the apparatus invented by Mr. Smith.

The President, in subsequently inviting questions and criticism, said he was sure all would join with him in expressing their pride and admiration of the demonstration which had been shown them that evening by their fellow member, Mr. W. H. Smith. It was undoubtedly a great step forward in artificial lighting, and they could congratulate themselves on the fact that this had been first displayed to that Club.

Mr. Maclean handed round a print from a negative he had taken with the lamp, which was much admired.

Mr. Packham said, in his view, it was the acme of perfection for both professional and amateur, and it would not be surprising if it were more favoured than even daylight illumination, for by this apparatus they could always get the same amount of actinic power.

Mr. Beales also gave it as his opinion that this was a step in advance of even daylight, and he regarded it as a very smart invention indeed. He had ordered three of the appliances, and should start using them, as he regarded this as the future light.

Very enthusiastic votes of thanks were then passed to Mr. Smith for his lecture, and to Mr. Beales for his help in putting the light to a practical test before the audience.

#### THE BRITANNIA WORKS COMPANY.

The following is an extract from the Directors' report for the year ended October 31, 1899, to be presented at the Third Ordinary General Meeting, to be held at Winchester House, Old Broad-street, E.C., on Wednesday, November 29, 1899:—

The Directors have the pleasure to report that after payment of working expenses, Directors' fees, income-tax, &c., and making provision for doubtful debts, the net profit for the year's trading is 51,928l. 12s. 2d.

† This amount, with 5637l. 3s. 1d., brought forward from last year, gives 57,565l. 15s. 3d. for appropriation.

† The Directors have paid an interim dividend on the ordinary share capital, for the half-year ended April 30, 1899, at the rate of 8 per cent. per annum, free of income-tax, absorbing 7600l.; and for the same period they have paid the dividend on the 6 per cent. preference shares, amounting to 5700l. Since then the second dividend on the 6 per cent. preference shares has been paid. From the balance the Directors recommend that a dividend be paid on the ordinary share capital for the half-year ended October 31, 1899, at the rate of 12 per cent. per annum, free of income-tax, making with the above interim dividend 10 per cent. for the year; this will absorb 11,400l. On this dividend, by the terms of the profit-sharing scheme submitted at the last meeting, 718l. 15s. 10d. will be paid as bonus to the *employés*. Of the balance, 26,451l. 19s. 5d., the Directors recommend that 14,899l. be written off goodwill, processes, &c., that 8000l. be placed to reserve, and the balance, 3552l. 19s. 5d., carried forward.

The business continues to show satisfactory progress, the sales having been considerably larger than last year.

#### RESULTS OF THE "MAWSON" PRIZE COMPETITIONS.

The following are the results of Messrs. Mawson & Swan's Prize Competition, 1899:—

Class I.—The Best Snap-shot Photograph on Films only (5×4 and under), 5l., 4l., 3l., 2l., and 10 of 1l. each.—E. D. Girdlestone, A. Thomson, W. B. Green, W. H. Barraclough, J. W. Ellis, H. Phillips, W. G. Elcombe, J. L. Griffiths, E. G. Boon, Mabel Metcalfe, C. F. Inston.

Class II.—The Best Snap-shot Photograph on Plates or Films (5×4 and under), 5l., 4l., 3l., 2l., and 10 of 1l. each.—T. Hartley, W. Kilbey, C. F. Inston, H. Holt, H. C. Leat, A. P. Russell, G. Edwards, T. J. Crofts, W. B. Green, E. W. Philpott, C. Church, W. Mitchell, W. H. Barraclough, E. A. Boon, W. H. Pallister, J. T. Rodgers.

Class III.—The Best Landscape or Seascape Photograph on Plates or Films (8½×6½ and under), 7l., 6l., 5l., 4l., 3l., 2l., and 10 of 1l. each.—T. Hartley, W. Norris, J. Patrick, V. C. Baird, W. M. Dodson, J. K. Ayling, J. W. Ellis, W. H. Berkeley, A. J. Squires, E. W. Philpott, W. Atkinson, T. Stratton, A. W. Cooper, R. H. Beavan, C. F. Inston, W. Haslett, W. Kilbey.

Class IV.—The Best Portrait (Groups included), Photograph on Plates or Films (8½×6½ and under), 7l., 6l., 5l., 4l., 3l., 2l., and 10 of 1l. each.—Graystone Bird, F. W. Fielder, C. P. Cassine, F. Coop, N. Elliott, F. M. Sutcliffe, W. G. Clark, A. Dwin, S. H. Wrighton, W. McLean, W. Lindhe, F. W. Beilby, W. Mitchell, J. Walker, G. Edwards, W. Atkinson.

#### AT THE CAMERA CLUB.

The Camera Club lectures have not, during the past week or so, partaken of that photographic character which one is led to associate with that comfortable home of things photographic. Still, it is difficult in these days to take up any subject which does not in some way employ the camera, so that, either directly or indirectly, the Club members get their appetites whetted by the varied bill of fare prepared for them by the energetic Hon. Secretary, Mr. Godfrey.

On Thursday, the 9th inst., Dr. Hampson gave a lecture on "Liquid Air," which aroused the very greatest interest, and his discourse was not only abundantly illustrated by unique experiments, but the members were enabled to see the air in process of liquefaction. So far as we can remember, this interesting process has never been made manifest to an audience before. The apparatus used is of Dr. Hampson's invention, and consists of a small cylinder, the interior of which is crowded with the convolutions of a narrow-gauge copper tube, the whole arrangement being jacketed in a heat-excluding cover. First the copper tubing was cooled by the expansion of air and carbon dioxide, and shortly afterwards air alone was admitted. In a short time it was visible in a liquid state running from the apparatus. Dr. Hampson gave a capital lecture, and made a difficult subject easily understood. A short discussion followed the lecture, the remarks of the speakers very naturally trending towards the behaviour of photographic sensitive surfaces under the action of such intense cold as was represented by liquid air.

On the following Monday Mr. Spiers gave an admirable account of photographic work at high altitudes, illustrating his paper with some truly magnificent pictures taken in the Matterhorn district.

Mr. H. W. Chubb gave, on Thursday, 16th, a most interesting lecture on mediæval and other locks, and it was most thoroughly illustrated in a somewhat novel manner. First, the walls of the Club-room were covered with large and elaborate drawings of locks and keys of nearly every conceivable pattern. These served to illustrate the first portion of the lecture. Next came a lantern section, which included a number of most cleverly contrived mechanical slides, by which the movement of different forms of locks was beautifully shown. Lastly, the lecturer used an aphengescope, or reflecting lantern, for showing parts of locks and keys in a manner which would have been impossible by any other means, so that in this case the Camera Club enjoyed a well-delivered lecture on a non-photographic subject, which was illustrated by means which were of peculiar interest to them.

But, without any such elaborate setting, Mr. Chubb made the subject, of which he is a master, most interesting and entertaining. There is nothing *per se* in a modern lock which would tempt any man to express deep interest or keen delight; but, when the evolution of the lock and key is followed up from the simple bar running into fixed staples, it must be conceded that it is a very fascinating subject. Mr. Chubb dealt with it under two aspects, artistic and mechanical. The first key was shaped like a hook or scythe, the point of the instrument being used to raise a pin, which dropped into a sliding bar. Such a lock was used in the time of Pharaoh, 4000 years ago. Much the same arrangement was shown in the lock which the lecturer had brought from a barn door in Switzerland. Next were shown specimens of Roman locks, chiefly from Pompeii, and these, strangely enough, were comparable with present-day locks made in China and Japan.

One curious key, of Roman origin, formed part of a finger ring. This probably was the key of a wine cellar, for, when a wealthy Roman took to himself a bride, she was presented with all the keys of the house save one, and that was the key of the cellar. A curious feature of this particular key was, that the barrel was pierced right through, so that no fluff could lodge in it, as it so often does in a modern key. Mr. Chubb said that this old Roman notion was patented about twice every year in our own model Patent Office, which will calmly allow aspiring inventors to indulge in such vagaries so long as they pay the necessary fees. He also showed a key ring which he wore on his own finger, remarking that the New York customs officers were so interested in the curiosity that they chalked his luggage without examining it.

Keys of the early Renaissance and the Renaissance proper were also shown, together with many old curious locks. Some of these were of the most elaborate decoration, and it was not difficult to believe the statements of an old French locksmith, who states, in a book upon the subject of his craft, that some keys took a man twelve months of steady work to make. The trade guilds at that time were far more onerous in their conditions than are the trades unions now, but their efforts did not tend to make a man scamp his work, but to improve it, no man being allowed to become a member before he had sent in a masterpiece showing what his hands could do.

The lecturer concluded with an interesting account of the manner in which modern locks and safes were made, especial attention being given to the wonderful time and combination locks which are attached to strong-rooms at banks, &c. Pictures were also shown of collections of burglars' tools made for the purpose of breaking into these strong-rooms, and defying bolts and bars. Keyholes are now unsafe, for they afford lodgment for small charges of dynamite the explosion of which would wreck an ordinary lock. In a modern safe, therefore, the keyhole is absent. The chronometer lock inside is set to a certain hour, say nine a.m., and, when nine o'clock strikes, the mechanism acts automatically and the bolts are withdrawn.

#### Our Editorial Table.

THEORIE UND GESCHICHTE DES PHOTOGRAPHISCHEN OBJECTIVS.

By DR. MORITZ VON ROHS. Berlin: Julius Springer.

SINCE the publication of Dr. Josef Maria Eder's volume of the *Handbuch*, dealing with photographic lenses, this is unquestionably the most im-

portant work which has been published on photographic optics. The author, as one of the members of the scientific staff of the Carl Zeiss Optical Works, at Jena, has not only had special opportunities to investigate various branches of the subject, but has been able to avail himself of the services of trained calculators in giving a graphic representation of the possibilities of most of the photographic lenses which have been constructed during the last sixty years. As might be expected, the result is a masterly and comprehensive treatise that will rank as a standard book of reference on photographic optics.

The first part of the work, covering some ninety pages, deals with the theory of photographic lenses and their defects. The exposition is lucid, and the author has made it his aim to bring this portion of the work within the grasp of the general reader.

The second part of the work, comprising about 300 pages, is an historical account of the development of photographic lenses from the single landscape lens of Charles Chevalier to the astigmatically corrected combinations of recent years. With pardonable pride we read Dr. von Rohr's acknowledgment of the valuable assistance he has received from the volumes of *THE BRITISH JOURNAL OF PHOTOGRAPHY*, and the Royal Photographic Society may also be congratulated upon the great service afforded by its library. The history of photographic optics is divided by the author into various periods, or schools, viz., the optics of the camera obscura at the time of the discovery of photography; the Franco-Italian opticians; the English-American opticians; and the Germano-Austrian opticians. The exposition enables the reader to trace very clearly the development of the various single lenses, the doublets and the triplets, and their variety will perhaps be a surprise to many photographers. In this brief account of Dr. von Rohr's work it would be an over-accentuation of the work of English opticians to quote his appreciation of their services. Goddard, Thomas Grubb, Andrew and Thomas Ross, and J. H. Dallmeyer, as leading figures of the old school, meet with due recognition, but whilst the author is not prepared to admit great powers of originality on the part of the last-named optician, the fact remains that his work was highly popular with photographers both here and abroad. As might be expected, the influence of the late Traill Taylor receives its acknowledgment. Dr. von Rohr justly points out that the patents secured by Continental opticians have limited the efforts of recent English opticians, but he also recognises that, whilst the doublet has been practically forbidden ground, notable lenses have been made of the triplet type, which may be regarded as a characteristically English combination. It is also deserving of note that the firm of Ross & Co., through Dr. Hugo Schroeder, was the first to take advantage of the new glass for photographic purposes, as the conentric lens due back to 1887, although it was not placed upon the market until 1892.

Turning to the Germano-Austrian school, it will at once be recognised that it comprises the men who have contributed the most important work to the optics of photography. J. Petzval, Adolph Steinheil, Professor Abbe, and Dr. Rudolph stand head and shoulders above other contemporary opticians. The detailed account which Dr. von Rohr has given of the work done by Dr. Adolph Steinheil and Dr. Rudolph constitutes a valuable addition to the literature of photographic optics. Nor should we omit to mention the great services of Dr. von Hoegh, as testified by the objectives he has calculated for C. P. Goerz. Drs. Kaempfer and Miethe, as representing the firm of Voigtlander & Sohn, have also indelibly impressed their names upon the roll of opticians.

The work concludes with a series of diagrams representing the residuum of spherical aberration and astigmatism in a large number of lenses referred to in the text. This is, doubtless, a very valuable index to the performances of the various lenses, but it must be examined with due regard to the conditions laid down by the author. The curves have been calculated, doubtless, with the utmost care and with a sincere desire to represent the lenses accurately, but the data are taken from specifications which do not necessarily correspond with the lenses actually upon the market. A patent specification serves to secure the right of the inventor to the essentials of the particular construction, but the lens may differ in its details. Thus we find Dr. Steinheil's orthostigmat, Type II., represented by curves calculated from the patent specification with aperture  $f/6$ , whereas the lens is manufactured with the smaller aperture,  $f/6.8$ . Comparisons must therefore be made by the reader with due regard to the data given.

We have only been able to give a brief sketch of Dr. von Rohr's book, but we trust we have made it clear that it is of great merit and worthy of serious study.

#### NATURE MOUNTS.

Messrs. PERCY LUND, HUMPHRIES, & Co., of Bradford, send us a packet of their Nature mounts. This is a new style of mount, made of stout, rough paper, adapted for postal cards and for every occasion where thick cardboard would be objectionable. The mounts are suitable for platinum, carbon, bromide, or gum-bichromate prints, but their employment for ordinary glazed sensitised papers is not advised. They are made in four special tints—grosvener green, playfield cream, duffel grey, and grey bark, selected to harmonise with the principal shades of carbon, gum, and platinum. Those who adopt these mounts are advised to use paste sparingly, roll the print well down with a squeegee, and place under a weight for a time to ensure flatness. They are supplied in

assorted packets, or packets containing one tint only. A white tint is the latest introduction to the series, which should be in great demand for a more tasteful mounting of prints than is required in the production of the "usual thing."

We have received from Messrs. Osman & Co., of 182 and 184, Commercial-street, London, their forty-page illustrated price-list of horticultural sundries, fancy goods, and imperishable palms. The latter might be found of service by our professional readers in the adornment or decoration of the studio.

Messrs. DAWBARN & WARD, of 6, Farringdon-avenue, E.C., have commenced the publication of a series of books on the useful arts and handicrafts under the general editorship of Mr. H. Snowden Ward. The first of the series, entitled *Designing and Drawing for Beginners*, by Mr. C. G. Leland, M.A., has just been issued, price 6d. The series is intended to be large and comprehensive, and it should be found of great use to practical students of the minor arts and crafts.

Messrs. HEPWORTH & Co., cinematographers, of Hurst Grove, Walton-on-Thames, send us some excellent examples of their cinematograph film work, accompanying which are a full synopsis of two entertainments with the optical lantern and cinematograph, given by Mr. Hepworth; a list for the trade only, and a detailed list of Hepworth film subjects for the cinematograph manufactured solely by Messrs. Hepworth.

#### SCOLI GLUE.

COLLOID, LIMITED, of 121, West George-street, Glasgow, write us: "With reference to the discussion that is going on in your *JOURNAL* re mounting, I am to-day forwarding you a sample tin of our scoli glue. This has been on the market now for over three years. It does not cockle the mount if only a thin layer is put on, and it is warranted to contain no acid or other material that would injure the photo."

\* \* Owing to great pressure on our space this week we have been obliged, at the last moment, to hold over several notices and reviews.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening November 29, 1899, at eight o'clock. "How I Photograph Domestic and Wild Animals," by Mr. Thomas Fall, F.R.P.S.

THE Hon. Secretary of the Hove Camera Club writes: "Will you kindly note in your next issue that the entries to our Exhibition close on Saturday next, November 25." *W. E. W.*

ROYAL PHOTOGRAPHIC SOCIETY.—Technical Meeting. Tuesday, November 28, at 66, Russell-square, at eight p.m. "Practical Three-colour Lantern-slide Making," by Mr. E. Sanger Shepherd.

THE AUSTIN-EDWARDS MONTHLY FILM NEGATIVE COMPETITION.—The prize-camera for the current month has been awarded to Mr. E. Thompson, 53, Croxteth-road, Liverpool, for his negative, *Black Kittens at Play*.

Messrs. ADAMS & Co., of 31, London-street, Greenwich, S.E., in sending us their price-list, observe that the Photographic Printing Department is under the control and supervision of Mr. A. Stephens, and is in addition to the already existing business of Mr. E. P. Adams (Adams & Co.). Albumen printing will receive special attention, the paper being sensitised daily.

CRYSTALS ETCHED ON GLASS.—Mr. C. E. Benham, of Colchester, has, it is said, produced some interesting effects by crystallising various salts in a thin layer on glass, and then exposing the glass to the vapour of fluoric acid. The crystals act as a "resist," and their microscopic forms are beautifully reproduced etched into the glass. The exposure to the vapour varies from three to five minutes, the glass being first well warmed to prevent the crystals from dissolving.

A THOROUGHLY practical lecture was that delivered by Mr. H. W. Bennett, F.R.P.S., before the Borough Polytechnic Photographic Society on the 15th inst., on "Architectural Photography," when, by the aid of a piece of chalk, blackboard, and duster, the lecturer succeeded in emphasising his points with considerable clearness. Sketches were made of several of the last Pall Mall exhibits in order to illustrate various defects and irregularities in the general composition and arrangement of architectural subjects.

Re HENRY R. TREVETHICK, photographer, 1, Orchard-street, Sheffield.—This debtor appeared for public examination at the Sheffield Bankruptcy Court on Nov. 16 last before Mr. Registrar Binney. The summary of accounts filed by the debtor disclosed liabilities amounting to 385*l.* 13*s.* 6*d.*, and assets estimated to produce 69*l.* 17*s.* 7*d.* The Official Receiver stated that the examination had been adjourned from the previous sitting of the Court in order that the debtor might be enabled to file a cash account. The account had since been filed, and, as it was satisfactory, he had no objection to the examination now being closed. The Registrar accordingly allowed the debtor to pass his examination.

THE Duke of Newcastle personally inspected the installation of Röntgen apparatus, on November 21, on board the *Princess of Wales*. In addition to the electrical necessities his Grace has provided all the materials likely to be of use in the photographic department. His Grace being an amateur photographer, no detail has been missed. Mrs. Blewitt (wife of General Blewitt) and friends are donors of the outfit for ss. *Spartan*, and, as Sir Peter and Lady Walker have provided the apparatus needed, all three ships will be now thoroughly equipped. The Duke of Newcastle has also provided a number of Dr. Walsh's books on the use of Röntgen rays, together with charts for reference, which are to be distributed to the surgeons on the hospital ships.

THE following are some recent additions to Messrs. Fuerst Brothers' list of cinematograph films: 9101, Coldstream Guards embarking on troopship *Gascon* (close view); 9102, Coldstream Guards embarking on troopship *Gascon* (showing the Royal Engineers in the foreground); 9103, Departure of troopship No. 4 (*Nubia*), with Scots Guards aboard, Southampton, October 28, 1899; 9104, 1st Battalion Rifle Brigade embarking on s.s. *Gascon*; 9105, H.R.H. the Duke of Connaught and party coming aboard to bid farewell; 9106, Soldiers waving "Good-bye" as ship leaves; 9107, Union liner, *German*, departing (close view, showing soldiers); 9108, Wiltshire regiment, church parade, the Sunday before leaving for the Transvaal; 9109, A Basuto "indaba" (animated war council); 9110, Royal Horse Artillery firing guns (good smoke effect); 9111, Brick battery in action (good smoke effect); 9112, Disappearing guns at Shoeburyness (good smoke effect).

ROYAL PHOTOGRAPHIC SOCIETY.—*Fellows Admission Committee*.—The next meeting of this Committee will take place on Tuesday, December 5, for the examination of the qualifications of applicants, who are referred to the following bases of qualification: Applicants must be members of the Society. They should furnish the names of one or more members of the Society to whom they are personally known. The receipt of the medal of the Society is in itself sufficient upon which to base an application for Fellowship. The candidate is expected to make a written statement of his qualifications in relation to one or more of the following heads: Important contributions to photographic knowledge, either in theory, practice, or invention; the production of notable work, either in pure photography or in the arts and sciences kindred thereto; work done in disseminating photographic knowledge, or any public service tending to the advancement of photography. Further particulars, forms, &c., may be obtained on application to the Assistant-Secretary, at 66, Russell-square, W.C.

Re L. J. JESSOP, photo-engraver, 25, Farringdon-avenue, London, E.C.—The first meeting of the creditors interested under this failure was held at the London Bankruptcy Court, under the presidency of Mr. Howell, Assistant Receiver. No statement of affairs was filed, but the liabilities were estimated at 1200*l.*, with assets consisting of shares valued at *nil*. The debtor stated that he began business in September 1897, in partnership as a photo-engraver, in the Strand. In the following February the partnership was dissolved, the debtor taking over the business, which was subsequently removed to 25, Farringdon-avenue, E.C. In the autumn of 1898 he sold the business to the Holborn Press, Limited, who agreed to pay him 2000*l.* in cash, and 2000*l.* in fully paid 1*l.* shares. The company carried on business for about six months, and then went into liquidation. The debtor stated that he had been without occupation since the failure of the company. He made no proposal to the creditors, and the case went into bankruptcy, with the Official Receiver as trustee. The debtor attributed his insolvency solely to the failure of the company. The public examination is fixed for December 14.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

November.	Name of Society.	Subject.
27.....	Bradford Photo. Society .....	Egypt. W. Claridge, M.A.
27.....	Camera Club .....	Lantern-slide Trial Evening.
27.....	Oxford Camera Club .....	Prize Slides.
28.....	Birmingham Photo. Society ..	Developers and Development. Prof. C. H. Bothamley, F.I.C., F.C.S., F.R.P.S.
28.....	Hackney .....	Technical Control for Pictorial Results. W. Thomas.
28.....	Leeds Photo. Society .....	In Search of the Picturesque. J. W. Wade.
28.....	Royal Photographic Society ..	Practical Three-colour Lantern-slide Making. E. Sanger Shepherd.
29.....	Borough Polytechnic .....	Gravura Paper. A. O. Baldwin.
29.....	Oroydon Camera Club .....	Conversational Meeting.
29.....	Photographic Club .....	How I Photograph Domestic and Wild Animals. Thomas Hall, F.R.P.S.
29.....	Southsea .....	Demonstration: <i>Velox</i> Papers and the New Developer Kachin. Donald A. Nightingale.
29.....	West Surrey .....	Outing Competition.
30.....	Camera Club .....	Travel in Persia. Basil Williams, M.R.A.S.
30.....	Leigh .....	Film Photography (Wellington & Ward's New Film). H. Wade.
30.....	Liverpool Amateur .....	Belgium. Dr. J. W. Ellis.
30.....	London and Provincial .....	Open Night.
30.....	Oldham .....	The Practical Treatment of Lantern Slides. J. Hall.
December.		
1.....	Ashton-under-Lyne .....	Elementary Photography Class.
1.....	Borough Polytechnic .....	Practical Evening: Lantern Slides.

### ROYAL PHOTOGRAPHIC SOCIETY.

NOVEMBER 21,—Mr. H. Snowden Ward in the chair.

#### ARCHITECTURAL PHOTOGRAPHY.

Mr. HENRY W. BENNETT, F.R.P.S., read a paper on "Architectural Photography," in which he dealt mainly with that class of work which had for its object the pictorial representation of some fine or characteristic piece of architecture rather than the accurate reproduction, which aimed at fulfilling the functions of working or detail drawings, and it was written specially in connexion with the architectural photographs in the Society's recent Exhibition. Referring first to the question of selection, the author said that no effort should be spared, and no time considered too great, for selecting a subject and studying the conditions requisite for expressing it in the most characteristic manner. Whatever the subject, it should possess some characteristic architectural feature in addition to its photographic quality, and also a due proportion of foreground and extreme distance, an entire absence of any suggestion that

it is incomplete or imperfect; the perspective should not appear strained or unnatural, the composition should be good, and the disposition of light and shade should be harmonious and satisfactory. One very weak point in many architectural photographs was the want of sufficient foreground, the sense of the space between the observer and the nearest vertical object being lost if the floor was cut off too closely. Distance was quite as important as in landscape work; there should always be something, or the suggestion of something, beyond the principal object of interest. Nothing was worse than to see the whole of a subject in one plane, as was frequently the case when doorways were photographed, in which case the mere opening of the door would give the suggestion of distance and save the picture. In this connexion the author emphasised the importance of selecting a standpoint yielding an angular rather than a square view, as the placing of the camera directly in front gave a result too geometrical to be pleasing, and destroying the sense of relief. The Exhibition contained many examples, some of them by leading workers, of the disregard of the quality of completeness, an arch or column being broken off just incomplete, and this was a fault which could not be too strongly condemned. A considerable part of the paper was devoted to the discussion of questions of exposure, development, and printing. For interior work, Mr. Bennett was of opinion that the most suitable weather was when there were plenty of light clouds, the light being then so diffused that the dark corners were well illuminated and the lighting of the whole building was soft and harmonious. With regard to the camera, rigidity rather than lightness should be studied, the focussing should be from the front, and the extension should range from two-thirds to at least twice the length of the plate. The front should be capable of rising to the extent of one-third the length of the plate, and the bellows should be attached to the rising portion of the front, to prevent the cutting off of any portion of the picture. The use of a tripod stay, consisting of three slotted bars connected by screws and attached to the legs of the tripod, was strongly recommended for the prevention of slipping, an additional safeguard being obtained by inserting the points of the legs in corks or indiarubber tubing. The lens should cover an angle of 100°, to allow of perfect definition to the margins of the plate when the lens was raised much above the centre. The necessity for good perspective rendering applied with great force to architectural subjects, and so much depended on the relation between the focus of the lens and the size of the plate, that this question of perspective should receive particular attention. Mr. Bennett thought that the most satisfactory length of focus ranged from rather less than the length of the plate to about 1½ times, or for a 12×10 plate from 10 or 11 inches to 16 or 18 inches. An 11-inch lens on a 12×10 plate, if judiciously used, would not produce the exaggerated perspective that disfigured photographs taken by very wide-angle lenses, and would include sufficient of the subject to produce a pleasing composition under all ordinary circumstances. The camera should be placed at about the normal height of vision. Working from a height had nothing to recommend it, and was condemned by the results obtained by that method. Plates of moderate rapidity were to be preferred. With regard to exposure, actinometers were of no practical value for interior work, the only reliable method being to estimate the exposure from the appearance of the image on the ground glass. The lecturer preferred to develop for density first and for detail afterwards, commencing the development of all negatives with a standard developer containing in each ounce 1½ grains pyro, 1½ minims ammonia, and ¾ grain ammonium bromide. He aimed at securing a negative with a rather longer range of gradation than the printing process would render, and then, by covering the glass slide with tracing paper, and cutting away or adding to the paper as required, he produced a more harmonious and satisfactory rendering than would be possible by developing a thinner type of negative.

Mr. Bennett's paper was illustrated by sketches of architectural pictures exhibited at the recent Pall Mall Exhibition, and by slides from his own negatives.

Mr. SEBASTIAN DAVIS raised the question as to the relative advantages of tilting the camera and using the swing back, as against the use of a considerable rise of front. He preferred the latter method.

Mr. BENNETT said his invariable practice was to level the camera, with the front and back vertical and parallel, and not to move it; it was for that reason he emphasised the necessity of using a wide-angle lens, so that the lens might be raised without cutting off the corners of the picture. Many interior subjects required a prolonged exposure with *f*/32; if the front and back of the camera were not parallel, it would be necessary to use an exceedingly small aperture to get good definition, and the exposure would consequently be so prolonged as to render many subjects impossible.

The Rev. F. C. LAMBERT referred to the difficulty of securing detail in dark roofs, and remarked that such subjects could be more conveniently undertaken when there was freshly fallen snow outside, a great deal of additional light being then reflected into the darker portions of the structure. He asked what plan Mr. Bennett adopted for focussing in dark interiors, &c.; whether he recommended artificial illumination by means of magnesium wire or otherwise.

Mr. BENNETT thought that dark roofs should be shown dark in the photograph. For focussing in dark places, when the authorities would not permit the use of lights, he generally put a sheet of white paper at such an angle that it would reflect what little light there was on to the object to be focussed, and by the aid of a powerful magnifier he managed to get the image fairly sharp. He did not advocate the use of magnesium wire, which gave a patchy and unnatural result.

Mr. E. MARRIAGE showed some slides illustrating the results obtained with lenses of different focal lengths, and said he preferred a lens of longer focus than Mr. Bennett had suggested, although the question largely depended upon the taste of the worker.

Mr. J. C. S. MUMFERY thought the question of long or short focus was much influenced by the character of the building. A Norman doorway often looked extremely well in a front view because it was geometrical in design, and the solid geometry of the structure was thus emphasised. A dark roof was sometimes a great advantage from a pictorial point of view, the gloom imparting majesty and beauty to the whole, and it was frequently intentional in the building.

Some further remarks were made by Messrs. BOLAS, BECKETT, and others to which Mr. BENNETT replied, and the CHAIRMAN expressed the indebtedness of the Society to the lecturer for giving a paper so full of valuable hints and thoughtful suggestions.

#### COMING EVENTS.

November 28, "Practical Three-colour Lantern-slide Making," by Mr. E. Sanger Shepherd. December 5 (Lantern Evening), "Lincoln Cathedral," by Mr. Frederick H. Evans.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 16.—Mr. H. C. Rapson in the chair.

Mr. S. H. FAY showed a speaking example of what may happen to a photograph by its being printed on two different makes of paper, or on pieces of the same paper cut from the sheet in different directions. The same negative was used in printing the two portraits, but it was found on measuring the same that one was two millimetres longer in the head than the other. The shorter of the two was right for length, but added somewhat to the true width of the face. The longer one, on the other hand, was fairly right for the width, but falsely represented the length of the head. The difference was everything between a face tending to fulness and one having the contrary characteristics.

Mr. WALTER D. WELFORD brought forward a new flashlight powder which he had received from Messrs. Fuert Brothers. For it was claimed an absence of all smoke, residue, and explosive properties, while, on the other hand, it was not based upon chlorate of potash or picric acid. It gave an exceedingly brilliant flash. Two quantities were fired, and, although smoke cannot be said to have been absent, yet so little was there that it readily dispersed and was lost. In making flash exposures of a group there is often a desire on the photographer's part to be in the group. For this purpose a length of touch paper, which is also supplied, will be found useful.

#### STRIPPING NEGATIVE FILMS FROM GLASS.

Mr. FRANK KELLOW described an easy method for removing and transferring gelatine films from glass. Many people, he observed, saw in such operations as those he was about to demonstrate great difficulty and risk of damage, but this was mostly due to fancy. He had saved by its means many negatives which had been accidentally cracked, and, as this might occur with anybody, he proposed to show the *modus operandi*. A formula was published some time back composed of carbonate of soda and formalin, followed by hydrochloric acid. With this, however, he found the gelatine rather apt to blister. For the carbonate of soda he therefore substituted caustic potash. The following solutions are made up:—

A.	
Ten per cent. solution of caustic potash .....	$\frac{1}{2}$ ounce.
Commercial formalin .....	$\frac{1}{2}$ "
Water .....	5 ounces.
B.	
Hydrochloric acid .....	1 part.
Water .....	60 parts.

The negative is put for five minutes in Solution A, followed by a similar period in Solution B. If the negative be cracked, a little preparation is required, or the sharp edges of the glass will cut through the gelatine. The method he adopted was to take a clean piece of glass upon which the glass side of the negative was affixed with Canada balsam, thinned down with benzole, previously heating the glass plate. It was then set aside to harden for some twenty-four hours, when it could be treated as described. This applies only to negatives of which the glass is cracked but the film not broken. With negatives of this latter category a further difficulty is encountered. Means must be taken to fit the severed piece exactly to its counterpart in the way described for the cracked glass. A solution of pure gelatine is then prepared and poured hot over the whole of the film, allowed to set and dry, afterwards being soaked in formalin solution.

In reply to an observation, he agreed that cobbler's wax or marine glue would serve instead of the Canada balsam, but he had not used other than the last-named. The hot gelatine solution had not, in his hands, melted the gelatine film or spoiled the image. Probably, as Mr. Haddon suggested, the developed film was sufficiently tanned to withstand the solvent action of the hot solution. After the immersion in the acid bath, B, the film readily came away, and could be transferred to a new glass, or reversed, as desired. It may then be dried, washing afterwards to get rid of the acid. It was curious to note that this method did not act with other than developed and fixed plates. He objected to the carbonate of soda on account of its tendency to unevenly stretch the film.

Mr. P. EVERITT thought that its power of stripping a developed and fixed film, while refusing to bring away that of an unexposed or undeveloped plate, would be explained by his idea of the action that went on. The fixed film he likened unto a sponge. The particles of silver unexposed would lie near to the back of the plate, and these fixed out would leave the film full of minute interstices. The formalin hardened the surface, and the acid worked through underneath, and the sponge formation facilitated the removal of the film.

Mr. A. HADDON thought that he would prefer the use of hydrofluoric acid to dabbling with caustic potash. Unless the former were very strong, it would not be so harmful. He thought, too, that the acid from Solution B might be removed at once by immersion in a judicious blend of alcohol and water.

Mr. S. H. FAY preferred the preparation made by Avery for stripping purposes. It was a very expeditious operation. He usually cut the negative film through with a knife, about one-eighth of an inch from the edge all round. This gave a new and clean edge to the film. He then flowed over the plate a small quantity of the formalin and spirit solution, with a few drops of fluoric acid. A piece of paper served to guide the stuff over, and the fingers need not come into contact at all with the mixture. After fifteen or thirty seconds, the film would probably lift up; if not, another application would ensure its removal. A good way to remove the film, when treated, was to rub down upon it a sheet of good surfaced paper—not a bibulous sample; lifting a

corner, and with it the film, one could strip the two together without fear of damage to the gelatine. The hydrofluoric acid was in such small proportion that little harm could result from it, but the application of several more doses of the formalin and spirit would practically remove it. For celluloid films some other treatment was required. He coated the gelatine film with gelatine solution, and, after drying same, put the whole into a solvent of celluloid. The supplementary coating of gelatine gave the negative film sufficient body to stand handling.

**North Middlesex Photographic Society.**—November 13, Mr. J. MacIntosh in the chair.—Mr. E. J. WALL gave an interesting lecture on

#### THREE-COLOUR WORK.

He explained the difference between colour photography by means of pigments and by the transparency method, and the reason why different colours had to be used for each method. He described the method of preparing suitable screens of red, blue-violet, and green, as in the Ives process of colour projection, and also the way in which prints in pigments were produced. Slides by Ives's process and that of Joly were projected on the screen. In the former, the three separate coloured images were shown and then combined, and, in the latter, the slide was shown without the special screen of ruled coloured lines, and afterwards with it the lines in the slide cutting out those in the screen where they were not wanted, so that a coloured image resulted.

**Bath Photographic Society.**—November 8, Colonel H. H. Sealy presiding.—This was the first open meeting, and the Committee had invited all interested to be present. Mr. J. T. SANDELL, of the Sandell Plate and Film Company, Limited, gave a demonstration of the new films issued by the firm. The lecturer prefaced his demonstration with some particulars of emulsion-making, and pointed out the method by which he considered perfection in plates and films was obtainable. A series of transparencies were projected on the screen, illustrating very difficult subjects successfully treated. A number of prints of large dimensions were also shown. Having explained the details of multiple coating of a suitable transparent base, like glass, and the enhanced value of the principle as adopted in the new films, he proceeded to develop some of these, pointing out possible defects and means of avoidance. Many questions were asked and replied to, and at the close the lecturer was thanked for his courtesy in visiting the Society.

**Leeds Camera Club.**—November 15, Mr. W. J. Warren (President) in the chair.—A lecture, illustrated by lantern slides, was given by Mr. S. MARGERISON on the subject of

#### OLD CHURCHES AND THEIR INTERESTING FEATURES.

In the course of his remarks the lecturer said: The first thing a tourist seeks when resting at any out-of-the-way district is the church, whose associations are always interesting, its antiquity undoubted, and its various transitions through often troublous times clearly indicated in its predominant features. The subject was of great interest, far too much for any single individual to undertake to establish a permanent record of all which it might be advisable to produce, and the lecturer hoped that every photographer would, whenever opportunity arose, contribute his share by obtaining a record of any interesting old feature, without which, as time wore on, it might be lost. Beginning from the outside, and working from west to east, Mr. Margerison traced in succession the leading features dominating the structure, and their variations under different styles of architecture, from the ancient Saxon down to modern times. He showed Bottesford, with its stocks and whipping-post adjoining the church, indicating that the power possessed by the churchwardens of olden times had certainly considerably diminished since then. The church crosses, too, were interesting, as seen in the examples occasionally met with, which very often existed even before the church itself, and formed the only meeting-place of the early worshippers. The towers and spires were important features in almost all old churches. Claypole, with its fine spire; Earlsheaton, with its old Saxon tower; Rothersthorpe, with its saddleback top, and many others equally noted, were passed in view before the audience. The porches, windows, consecration crosses, the poor-boxes, with their three different locks, were dealt with, and many beautiful examples of the founts shown, these latter in nearly all cases at or near the entrance to the church, and so symbolising the entrance of the baptized into Christianity. As time wore on, pulpits began to appear, indicating the necessity of the priests having to personally expound their views or contradict their opponents; while the hour-glass, as found above some old pulpits, was an indication of a suitable time limit to their eloquence. The interior arrangements of the aisles, chancels, and other parts were in turn alluded to, and fully represented. The trend of all the architecture, said the lecturer, led to the central feature of the whole church, the reredos and altar, the emblem of Christianity itself.

**Newcastle-on-Tyne and Northern Counties Photographic Association.**—At the last meeting of this Association Mr. HENRY WADE, of Manchester, attended on behalf of Messrs. Wellington & Ward, and gave a most interesting demonstration of that firm's new stripping film. This new product of the Elstree firm has been so frequently described lately that it is only necessary to say that it forms quite a revolution in photography, and is adapted to a great range of work, from use in the roll-holder of a hand camera to making enlarged negatives. To the carbon printer or collotypist it will be of immense advantage, as, when stripped, it can be printed from either side without loss of definition. It lies perfectly flat and is very tough, and, with ordinary care, its manipulation presents absolutely no difficulty.

#### FORTHCOMING EXHIBITIONS.

1899.

November 24, 25. .... Longton and District Photographic Society.  
Thomas Mottershead, 43, Stafford-street,  
Longton, Staffordshire.  
" 27-Dec. 18 American Institute Photographic Salon (New  
York). Hon. Secretary for European Exhibitors,  
H. Snowden Ward, 6, Farringdon-  
avenue, E.C.

- December 7-9 ..... Hove Camera Club. C. Berrington Stoner,  
24, Holland-road, Hove.  
,, 11-Jan.1900 Huddersfield (Invitation). W. A. Beevers, Cloth  
Hall-street, Huddersfield.  
,, 27-30 ..... Borough Polytechnic Photographic Society. Hon.  
Exhibition Secretary, E. J. Hoar, 59, Hillingdon-  
street, S.E.  
1900.  
January 29-31..... Southsea Amateur Photographic Society. F. J.  
Mortimer, 10, Ordnance-row, Portsea.  
April 3-7 ..... Birkenhead International. C. F. Inston, 25, South  
John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

THE following applications for Patents were made between November 6 and November 11, 1899:—

- PHOTOGRAPHS ON GLASS.—No. 22,136. "An Improved Method of Producing Photographs on Glass for Hand-painting Purposes." G. J. SERSHALL and A. F. BIDDLE.  
CAMERAS.—No. 22,195. "Improvements in and connected with Photographic Cameras." A. C. SMITH.  
SHUTTERS.—No. 22,225. "Improvements in Shutters for Photographic Plate-holders." Communicated by N. Bull. Complete specification. A. J. BOULT.  
ANIMATED PICTURES.—No. 22,289. "Improvements in Photographic Apparatus for the Production of Animated Pictures." H. OLIVER.  
CAMERAS.—No. 22,346. "Improvements in Photographic Cameras." Complete specification. F. A. FICHTNER.  
PHOTO-MECHANICAL PRINTING.—No. 22,350. "Improvements relating to Photo-mechanical Printing Plates or Colour Printing." Communicated by the firm of Meisenbach, Riffarth, & Co. J. WATTER.  
CAMERAS.—No. 22,358. "Improvements in and relating to Folding Photographic Cameras and to Plate and Film-holders therein." Complete specification. C. P. GOERZ.  
SENSITIVE COATING.—No. 22,370. "A New and Useful Process for Covering Plates or Rollers with a Photographic Substance Sensible to the Action of Light." E. ROLFFS.  
WASHING PLATES.—No. 22,371. "Improvements in Devices to be Used in Washing Photographic Plates or Films or the like." H. COVENTRY.

## Correspondence.

- \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* We do not undertake responsibility for the opinions expressed by our correspondents.

### SOME PRINCIPLES OF DEVELOPMENT.

To the Editors.

GENTLEMEN,—Mr. Micklewood criticises the summary of my lecture given on p. 716. This summary must be taken as another man's impressions in short of what I said at the Camera Club. I have in no way revised it, and should have to do so in some important respects before I could endorse it. At the same time any imperfections probably arose from the fact that I spoke extempore and rapidly.

I doubt whether it is possible to condense the principles with sufficient accuracy in a few short paragraphs. For instance, although I can endorse the general principle marked "a," I expounded in my lecture the very exceptions which Mr. Micklewood brings forward as a criticism on the principle, and in fact Mr. Micklewood omits quoting that part of the summary which indicates exceptions.

I have revised a full report to be published in the Transactions of the Camera Club. No doubt there is matter in it open to criticism, but until that is published it is idle to discuss the paper.

Mr. Micklewood's views on the progress of development in over-exposure are not borne out by exact trials. In any exposure, over or under, the contrast between any two tones which have a difference of deposit increases with length of development up to a certain limit, although with some plates (prone to fog) that limit is reached before maximum density in the high lights is attained. To obtain this maximum contrast with an over-exposed negative, the negative is very dense, and takes long to print. Most photographers stop the development of over-exposures long before maximum contrast is attained.—I am, yours, &c.,

Hereford, November 18, 1899.

ALFRED WATKINS.

### AUTOMATIC SLIDE-CHANGING.

To the Editors.

GENTLEMEN,—Your issue of November 17 contains a letter from Mr. W. D. Welford, in which he refers to my patent automatic slide-changer. I am pleased to know that such an expert as he was so impressed with it, especially when I remember that it was in very crude form when I,

though not an *employé* of the Dunlop Tyre Company as Mr. Welford supposes, showed it to him in January 1897, and fitted it up for his lectures.

Since that time the changer has been perfected, and by next season I hope to have it placed upon the market in forms which will be suitable for any of the present-day lanterns, thus enabling lecturers to have the means of changing their own slides at the exact instant required without the usual signal to the operator, which I think you will agree is objectionable and unsatisfactory.—I am, yours, &c.,

ALFRED SUMMERS.

Marlowes, Kilmainham, Dublin, November 20, 1899.

### "THE ABSENT-MINDED BEGGAR."

To the Editors.

GENTLEMEN,—It is a feature of the photographic press, that for a penny or twopence you can obtain all the general information contained in the paper, and also as much further special information as you like to ask for.

Last week four papers, between them, gave free special information to 180 correspondents, which may be taken as a fair average number.

If for, say, twelve weeks every querist sent a postal order for one shilling with his questions, he would receive value for his money, and a total sum of 108*l.* could be handed over to the War Funds.—I am, yours, &c.,

P.

[Our correspondent's suggestion is an admirable one; and, if any of our readers care to forward us their shillings, we shall be pleased to transmit them to the editor of the *Daily Telegraph*.—EDS.]

### THE BUSCH LENSES.

To the Editors.

GENTLEMEN,—I have pleasure in informing you that, at the recent photographic Exhibition held at Stuttgart, Busch's lenses were awarded a silver medal, an indication that, notwithstanding the firm's great age, which with the advent of 1900 will have reached 100 years, they are still in the forefront.

It is interesting to note that during this year three of the workmen have celebrated their jubilee of employment in the factory.—I am, yours, &c.,

HENRY F. PURSER.

33, Hatton-garden, E.C., November 20, 1899.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

SPOTS ON MATT-SURFACE PRINTS.—Will "Photographer" send us his address. A letter awaits him.

S.—Of the two we should be inclined to select Mr. Welford's, owing to the large amount of successful work he has done with it.

PERCY LYNE (Hull).—We cannot undertake to answer questions by post. It is, moreover, a rule of ours not to mediate in a dispute unless both parties agree to abide by our opinion. Hence we are unable to help in the present matter. We return you the prints.

HARRINGTON & Co.—The machinery for making liquid air is supplied by Brin's Oxygen Company, of 69, Horseferry-road, London, S.W. You are, doubtless, aware that, owing to its rapid transition to the aeriform condition, it cannot be conveyed far from the place of origin.

AGENTS FOR ARISTO PAPER.—R. G. says: "Would you kindly answer, Is there an agent for Aristo paper in England? If so, where could I get some?"—Aristo is a term used both on the Continent and in the United States. If you specify the particular brand of paper to which you refer, we have no doubt one of the trade houses will obtain it for you.

PRESERVING A POTATO.—W. A. GAIN writes: "To 'CURIO.'—A five per cent. solution of formalin—one part of the commercial article to seven of water—is all that is required. I have a potato which I preserved in this manner above two years ago. It is in perfect preservation. Nearly all delicate organic substances may be preserved in this medium without loss of colour."

ACTION OF METOL ON THE SKIN.—SUFFERER writes: "1. Will you kindly inform me what is the date in the JOURNAL in which you have something to say about the evil effects of metol on the skin? I have been suffering recently from this cause, somewhat severely, and I should be for ever grateful to you if you could tell me what to do in such a case. 2. Will you also be good enough to inform me when Mr. Birt Acres' new light for lantern work will be ready?"—1. Better consult a medical man. Metol has an ill effect on some persons, and they have wisely given up its use, or work in finger stalls. 2. We cannot say; write to Mr. Acres, Northern Photographic Works, Barnet, N.

**RIGHT TO NEGATIVES.**—J. W. C. Yes, you are quite right; the three negatives belong to you, and not to the sitters. But you are quite wrong when you say, "Surely one can do as he likes with his own property." You cannot use the negatives for purposes of your own against the wish of the sitters. If they object to enlargements from them being shown, they can restrain you, by law, from exhibiting them, and, probably, also obtain their forfeiture or their destruction.

**DRYING OIL ON PHOTOGRAPHS.**—"METEORS" asks: "Can you tell me what will assist the oil to dry on photographs after they are finished? I am well aware that the damp weather makes against the drying, but I have an impression that painters use something to help the drying."—A drying oil is sold by all artists' colourmen which dries quicker than ordinary linseed oil. "Dryers" added to the paint also facilitates the drying. That can also be had from the colourmen.

**RED TONES ON MATT PAPER.**—TONING writes: "Would you kindly give me a formula or tell me where I could find one, for obtaining red tones with matt paper, P.O.P. for preference."—P.O.P. is not a definite article; all are not alike. It is possible to obtain tones on one that are not possible on another. The redder tones are secured by slight toning only. Treating the prints with a solution of common salt facilitates the securing of reddish tones, when the toning is stopped at an early stage.

**CLEARING SILVER BATH.**—J. CRAWLEY says: "During the last two or three weeks I have, from time to time, been sensitising a little albumenised paper. The bath became of a brown colour, and, as I read that it could be cleared by the addition of kaolin, I procured some. On adding it to the bath a violent effervescence took place, and a good deal of the solution was wasted. Is this the way that kaolin acts?"—No. Evidently what you have been supplied with is not kaolin at all, or it would not have behaved in that way. Kaolin causes no effervescence whatever.

**CLEANING GLASS.**—N. CROWE writes: "Will you be good enough to tell me the easiest way to clean off spoilt negatives? I, like most others, have a large number of spoilt negatives (failures) which I should like to clean off so as to use the glasses as covers for lantern slides."—The simplest way is to soak the plates in cold water for a day or two, and then put them in hot water, when the film will readily dissolve off. If, however, the negatives were developed with pyrogallie acid, or were alumed, they would be a little more refractory, in which case the services of a nail brush may be invoked.

**LEARNING PHOTOGRAPHY AS A PROFESSION.**—PATER writes: "I have a boy who seems to have a taste for photography. I shall be glad if you can inform me the best way to get him forward in it, so that he can get employment, as I am told that good salaries are given."—The best way will be to article the lad to a good house, but we should advise you to hesitate before doing so. The labour market at the present time is much overstocked with proficient hands, and is likely to be for many years to come, we fear. We think you have been misinformed as to the salaries that are generally paid nowadays.

**PHOTOGRAPHING SNOW AND HOAR FROST.**—C. W. E. says: "I am anxious, should there be an opportunity this season, to take some snow and hoar-frost photographs. Please tell me whether any special rules are to be observed. Are ordinary or rapid plates best? Can falling snow be successfully photographed?"—There are no special rules to be observed beyond judgment. Give a full exposure, and develop tentatively. We should employ plates of medium rapidity ourselves. We doubt if falling snow can be successfully photographed—that is, catching the flakes as they fall. When it is snowing, the light is generally very non-actinic.

**SPOTS ON PLATINOTYPE PRINTS.**—C. H. ELLIS says: "Can you help me with the enclosed? All my work in platinum comes out spotty, as by the enclosed specimen. I have kept the paper and pads dry, as usual. I have hitherto been successful, but cannot now master the matter. I should be much obliged if you could assist me in any way. I am working in London on the roof of a house. I can get them clear in the summer, but not this time of year."—The spots on the print enclosed appear to be due to particles floating on the surface of the developer, and so preventing its action on the print where the spots are. See that there are no particles on the print when it is developed, and that there are none floating on the solution when the print is applied to it.

**VARIOUS.**—CONRAD asks: "1. Will you advise me how to use the ortol developer, as described in your issue of the 10th inst., for bromide paper; whether a clearing bath would be necessary, what strength the fixing bath should be, and how long they should be fixed? 2. What is the best make of transparent colours for P.O.P. prints? 3. What is your opinion of radiotint, as supplied by Messrs. Houghton?"—1. The same as for plates, except that it should be used a little weaker, and, perhaps, with a little more bromide. But something will depend upon the character of the paper. All papers are not alike. No clearing solution is necessary. 2. Ordinary transparent water colours, such as you may obtain from Newman's, Soho-square. 3. They are for colouring photographs and are transparent, also easily applied.

**REDUCING AND INTENSIFYING PLATINUM PRINTS.**—PLATINOTYPE asks: "Would you kindly let me know if there is any method of reducing over-exposed platintype prints, and intensifying under-exposed prints? I have several 12x10 prints (platinum) which I should like to save if possible. Any formula on this subject will greatly oblige. Thanking you in anticipation."—If the prints were ours, we should make fresh, and that is the practice with professional photographers, and it is far less trouble than attempting to vamp up ill-timed prints. Furthermore, they are of little use in the end. The over-printed ones may possibly be reduced by treatment with dilute nitro-hydrochloric acid, but they would probably be faint prints when done. If there is no detail in the lights of the under-exposed ones, no method of intensification can, of course, bring them out. Better make fresh prints, and not waste time.

**STUDIO BUILDING.**—STUDIO says: "Enclosed is plan (not drawn to scale) of proposed studio, which I would be very grateful to have your opinion on: First, as to how far to carry glass up the roof? Second, would nine and a half feet of glass be sufficient from beginning to background end? A large triangle beam, as shown in plan, comes exactly in the centre of the room and is the roof's principal support, the builder saying it could not be removed. If you consider the amount of glass sufficient, as shown in plan, I think the base of the triangle could be raised to eight feet, resting on pillars at each side of the room as shown."—As the plan is not drawn to scale, we scarcely follow it. We should prefer the height from floor to eaves raised a foot at least. Eighteen feet from floor to ridge seems to us an unnecessary height for so small a studio. Nine feet six of glass will be sufficient, but it should start about four feet from the background end. We may say, however, that we fancy we do not fully realise the proposed structure from the sketch.

**VARIOUS.**—VARNA writes re answer given November 3: "1. The gelatine, glycerine, &c., adhesive compound on p. 1062 of ALMANAC, used by me for films, was ascribed to Fol by Captain Abney. 2. I see on p. 685 of JOURNAL, No. 2060, that Mr. Bolas seems to recommend lead plaster for that purpose. The limp plaster would probably be inconvenient. Would not lead ointment spread on cardboard answer the same purpose better? But would not the presence of some lead or grease on the film be detrimental in the developer? 3. My queries 1 and 2 (p. 704) were not so much as to the relative permanence of gold or uranium toning as to know if toning after fixing gave equally permanent and good results as toning before fixing. 4. Would zinc plaster or ointment do as well?—1. Some mistake; no such adhesive appears on the page mentioned. Send the formula you have used, we can then express an opinion. 2. We have not tried it, but should expect that the grease would prove an inconvenience. Why not try it yourself, and see if it answers your purpose? 3. If gold toning is employed, we think there would not be much difference. Uranium toning is always after fixing. 4. We can only answer this as we did query No. 2. The lead plaster might be spread direct on to thick cardboard.

**REPRODUCTION.**—C. F. A. writes: "I want to reproduce a half-plate negative. 1. What would be the best way to do so? 2. Would you recommend making the transparency on half-plate by contact printing, or on quarter-plate by reduction in camera? 3. What is the best kind of plate to use for the transparency? 4. I use an 8x10 camera with a half-plate one as a daylight enlarger, but as the lens is eight-inch focus, the half-plate camera I use will not extend far enough to copy half-plate same size. Would I get as good a result by reducing to quarter-plate for the transparency, and then enlarging to half-plate for the negative? 5. Is it the usual method of professionals to make the transparency by reduction? If so, what kind of plate do they generally use? 6. Could I make efficient enlargements with a daylight enlarger, such as I have mentioned, by using ordinary paraffin lamps with 1½-inch burners? 7. If so, what would be the best way to place the lamps so as to illuminate the negative equally? 8. As daylight is very unsteady, is there any means of testing the light to ensure correct exposure?"—1 and 2. By contact printing. 3. A slow plate or a photo-mechanical one. 4. No. 5. Slow plates, but often the transparency is made by the carbon process by professional photographers. 6. Yes, by interposing two or more thicknesses of ground glass to equally diffuse the light. 7. At equal distances apart. 8. The best way, in practice, is to make a trial exposure.

**LANTERN-SLIDE MAKING.**—LANTERN SLIDES writes: "I am starting to make some lantern slides, and find some difficulty with exposure by gaslight. I did not get a properly exposed slide even with fifty minutes. I was reducing 10x8 negatives with an optical doublet of about seven and a half inches, stop f-32. I had succeeded in getting fairly good results during the daylight in sixty seconds with cardboard reflector and ground glass in front of negative with a view of equalising the lights. I used an ordinary enlarging camera, large enough for 15x12 plates, but I am making a box with a fixed focus for reducing half-plates, using the seven-and-a-half-inch lens. I should have thought f-11 stop should have been sufficient. I placed the lens with the front combination towards the negative, and back of lens nearest the lantern plate (a Mawson's). I cannot find, in any of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANACS I happen to have by me, an article to help me in my difficulty, hence my troubling you direct. I may add that I used hydroquinone developer."—F-11 is quite small enough, even unnecessarily small. The lens was rightly placed. We cannot account for the long exposure found necessary unless it be that the gaslight was very feeble or it was placed a long distance from the negative. We should advise you to use a rapid lantern plate, and place the apparatus nearer to the source of light, and perhaps increase the size of the burner.

**AN ASSISTANT'S DIFFICULTY.**—A B C says: "A undertakes to teach B photography, and allows B 1l. per week. B, in return, gives A his services as an animal painter and assists in photography, and signs an agreement for three years not to open or assist within twenty-one miles of C. A now says, B signed an agreement for his (A's) lifetime, and not to open or assist under a penalty of 500l. B had no witness or copy; but there were two young ladies in the room adjoining who heard B say he would only agree for three years. After the three years had expired, A wanted B to sign another agreement; B declined to do so. B is still in A's employment, and has been since 1876. In case the above is binding, could B's wife open in her name and B assist?"—Without seeing the agreement, or a copy of it, it is impossible to give an opinion. A radius of twenty-one miles, unless under exceptional circumstances, seems to us a wide one, and might be ruled in a court of law "an undue restriction of trade." An agreement for a lifetime, we should not think was, if made, binding in a court.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE Thirty-ninth Annual Issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC is now published. The volume reaches the unprecedented total of 1516 pages, and is the largest yet produced. As hitherto, it is issued in paper covers, price 1s.; cloth bound, 1s. 6d.

The frontispiece is a bromide print by Messrs. Wellington & Ward, of Elstree, from a negative by Mr. H. Walter Barnett, of No. 1, Parkside, Knightsbridge. Many other illustrations are also given in the text matter.

Eighty articles, on a great variety of subjects interesting to photographers, and contributed by the principal authorities of the day, form a feature of the volume. The other sections are "Epitome of Progress during 1899," "Patented Inventions of the Year," "Miscellaneous Information," "Practical Notes and Suggestions of the Year," which, with the large collection of formulæ, tabulated matter, and a great deal of other information of use to all photographers, places at their disposal,

for constant reference, a fund of technical knowledge which is not to be found in any other photographic annual.

\* \* The 1899 Edition of the Almanac (20,500 copies) was entirely exhausted within three months of publication—a fact without precedent in the history of photographic publications

## EX CATHEDRÂ.

THE subject of the right to the negative has cropped up again in a case which came before the Yarmouth County Court a few weeks ago. The Judge is taking time to consider whether the negative belongs to the sitter or to the photographer. In order to assist our readers to a knowledge of previous decisions, we last week devoted an article to the enumeration of a number of cases in which it has been decided by Judges of the High Court and others that, in the ordinary relations between photographer and sitter, the negative, subject to certain restrictions, is the property of the former. On the ground of what may be termed trade custom, the recognition of the fact that property in the negative resides in the photographer and not the sitter is so firmly established and obvious that we do not now expect a judicial expression of opinion to the contrary. If not opposed to law, it would be entirely out of harmony with equity, common sense, and precedent.

\* \* \*

STILL, the possibility of the Yarmouth Judge coming to a decision adverse to the photographer has to be borne in mind, and the resulting consequences taken into consideration. If it be laid down at this late date that the negative is the property of the sitter, the immediate effect might be to disturb the relations between photographers and their clients; but we cannot think that such a verdict would long remain unneutralised. It would be the instant duty of photographers to have a case tried before the higher Court, even to the ultimate extent of invoking a House of Lords judgment; for, if the photographer's right in his own negatives no longer exists, the stability and prosperity of the profession will be shaken to its very foundations

\* \* \*

WE call the attention of professional photographers all over the United Kingdom to the fact that they are menaced by

dangers of considerable gravity. Next session in all probability the House of Lords will be again asked by the artists and their publishing friends to rob photographers of their copyright in their own work; and at this moment we have the somewhat disquieting spectacle of a County Court Judge finding it necessary to take time to consider whether a photographer's negative made by the aid of his own material and skill is his property or somebody else's. We cannot possibly understand why there should be a doubt in the matter, any more than in the case of a painter who makes sketches for a portrait; a printer who sets types for the book he prints; an architect who makes plans for the house he is commissioned to design. But it is really not necessary to argue the matter further. We hope that, in the event of an adverse decision at Yarmouth, the Photographic Copyright Union will take steps to have it immediately wiped out or neutralised.

ON Monday afternoon last, at the offices of the Platinotype Company, Bloomsbury-street, London, a practical demonstration of the new oxy-magnesium light for portraiture, to which we referred last week, was given before an assemblage of well-known photographers. To the description of the system which we have already given the following additions may be made: The apparatus consists of a small electric battery; an oxygen gas-container on the well-known "gasometer" principle, and a bell jar, shielded by a concave radiator, to which oxygen is admitted from the holder. In the jar of oxygen a couple of strands of magnesium ribbon are suspended, and these are electrically fired by two wires from the battery. Just sufficient oxygen for the combustion of the oxygen is admitted to the bell jar, the supply being automatically controlled.

ON ignition of the magnesium, a light of the most intense brilliancy is obtained, and it is sufficiently actinic to allow of cabinet portraits being taken in a second or two. At the demonstration, test subjects, in the shape of dark and fair sitters, were photographed, the exposures being two and one seconds respectively, and the developed negatives proved to be exceedingly successful. As a result of the demonstration, we are convinced that the light has a very great future before it. The entire apparatus, which is about six feet high, may be comfortably stowed in the corner of the studio, the light is adjustable to any desired angle, and the weight, plus the water in the gas-holder, is only some forty pounds. A foot or two of oxygen and a few ounces of magnesium ribbon are sufficient for hundreds of exposures, so that, when once the apparatus is obtained, the cost of working it is exceedingly small. We are persuaded that in this ingenious adaptation of oxy-magnesium illumination to the purposes of studio portraiture the Platinotype Company have hit upon an idea which will be highly appreciated by professional photographers anxious to possess a cheap and efficient system of artificial lighting.

ALTHOUGH not a novelty in the country, the holding of a one-man exhibition by a provincial photographic society is a sufficiently rare and noteworthy event to call for prominent reference. We are informed that the Tunbridge Wells Photographic Society are to have an Exhibition of the collection of Eastern photographs by Mr. E. R. Ashton, which has recently been on view at the London Camera Club. The photographs

will be shown at Tunbridge Wells from the 6th to the 13th instant inclusive. We hope that Mr. Ashton's very fine series of interpretations of Eastern life by means of photography will attract a large number of visitors, to whom such unique studies cannot fail to give pleasure and delight.

FROM Messrs. F. & R. Speaight, photographers, of 178, Regent-street, W., we have received a specimen of the "Speaight Photo Christmas Card, 1900." This is a neat and tasteful production, which consists of a booklet,  $4\frac{1}{2} \times 3$ , artistically designed, comprising a primrose cover, having embossed in the centre of the first page a pattern of a miniature frame for mounting the photograph in, and "Christmas Greetings" stamped in mauve in the bottom right-hand corner. The four-page mauve inset, which is tied to the cover with dark mauve watered silk ribbon, has stamped on its third page a suitable greeting and space left for autograph. While congratulating Messrs. Speaight on their enterprise, we also desire to express surprise that such a comparatively few number of our professional readers engage in the production of Christmas photographic cards. For years we have been urging photographers generally to take up this interesting and remunerative branch of business.

#### BRONZES IN PHOTOGRAPHY.

THE present, for reasons to be mentioned, is not an unsuitable time for bringing to light a chapter of what, in photography may now be termed ancient history. It is over twenty years since—simultaneously with others, as events showed—we engaged in an investigation to discover the cause of certain mysterious spots which were prevalent in the mounted prints of a certain photographer, but which proved to be by no means confined to his prints, for it seemed as though an epidemic of spots were abroad. No chemical tests were capable of putting us on the right path; but, the moment we used the spectroscope on the flame from the ignition of a number of these minute spots cut out from the surrounding paper, the key of the enigma was found in the presence of copper. Not to make a long story of the further steps taken, it will suffice to say that each spot had an extremely small nucleus of metal, eventually proved to be a particle of "bronze powder." All the injured prints were mounted on so-called "gold-printed" mounts, the gold being merely bronze powder, and quite innocent of the noble metal itself. For scores of years past gold printing has been done by printing first in ink, leaving a sticky surface, with or without an admixture of bronze powder, and then giving the metallic appearance by dusting or brushing bronze powder over the whole surface of the paper or card whereon the printing was executed. When the non-adherent powder was brushed away, a very golden-looking surface was left behind; but, at the same time, a certain amount was left behind, and, by holding the printed surface at an angle with the light, it was not difficult to discern the metallic particles in greater or less number all over the paper or cardboard.

It took years of argument before it came to be a generally accepted fact that gold-printed mounts should be "anathema maranatha" for those who wished to preserve a reputation for permanent work. The vested interests of the printers were in danger, and they would not admit that their mounts could possibly be at fault. Then, when facts proved too strong for them, a very firm stand was made in the interests of a

favourite style with so many photographers by the statement that a new method of printing had been adopted which obviated all possibility of stray particles of metal being distributed over the prints.

All this, we have said, is ancient history, but we find that there is now upon the market an alarmingly large number of mounts which, though not printed in "gold," are yet equally fatal to silver prints by reason of a "gold" line—"gold-bronze," of course—placed round the space allotted to the print. Now, we would warn every one of the younger race of photographers, who have learnt their photography since the bronze disease became practically extinct, and by whom therefore the intensity of its incidence can scarcely be understood, that if they mount silver prints, more especially, perhaps, albumenised prints, the chances are very greatly in favour of white spots eventually making their appearance on their pictures.

We believe these mounts were devised with the idea of their being used for platinotype or carbon prints, and, if their use is confined to that purpose, no harm is likely to result to such prints. But it is to be remembered that, when these mounts are passed through the rolling press, some of the bronze particles are likely to become detached, and possibly adhere to the polished metal surface of the press, from there to be attached to some of the next lot of silver prints that are passed through. Hence the press, after being used for such mounts, should be sedulously and jealously cleaned before passing a print through. Before leaving this practical aspect of the subject, we suggest an old experiment as an object-lesson on these possibilities. Let a waste print be pasted over the gold of a gold-lined or gold-lettered mount, and the mounted print left in a damp place for a month. At the end of that time the maleficent properties of the metal will be evident by its having acted, through the substance of the paper, on to the surface of the print, and entirely bleached that portion of the print lying over it, the printing or lining showing light on a dark ground as a result of the destructive action of the metal.

The only way to use a bronze powder safely is by protecting it from being detached by imbedding it in a varnish of some kind. This is scarcely practicable for the printer, but, when the bronze is required to be used for decorative purposes, whether to patch up or ornament a frame or cover a surface, the most efficient mode is to suspend it in a celluloid varnish and apply it with a brush. Such a varnish or gold paint is now to be had commercially and economically.

Some light on the chemical aspect of the matter—the mode of action of the bronze in bringing about a destruction of the image, is thrown by some recent investigations on explosions of bronze powder—aluminium in [this case—that have taken place in the mills where the sheets of thin metal are ground up between rollers to make the aluminium bronze powder. It was found that this powder was capable of absorbing 1.4 per cent. of aqueous vapour from the air, and that it was further able to decompose the water so absorbed, the liberated gases being the source of the explosions. It is very probable that something of the same sort occurs with a print, and in the presence of these gases and of moisture it would be strange if the print did not suffer.

Before ending our remarks, we may point out that aluminium bronze gives an excellent light when used for flashes in lieu of, or by admixture with, magnesium powder, and it is also capable of explosion when mixed with potassium chlorate.

#### ORTOL, WHOLESALE DEVELOPMENT, REPEATED USE OF DEVELOPER, AND OTHER THINGS.\*

Pyro cannot come up to the scratch with ortol as regards all-roundness, to use a term associated with pyro, as, for one thing, it is not a good developer for bromide paper. Probably I shall be told, as of yore, that it can be used for this purpose; but "can" and "is" are two very different words when applied to the commercial side of photography. I assert that pyro is not used for the development of bromide prints, whether direct or enlarged, except as a scientific experiment or a little diversion in procedure to fill a spare half-hour at a society meeting, whereas ortol will come greatly into favour ere long for that attribute alone. Indeed, I should not be even a wee bit surprised should some old hand stick to his beloved pyro for negatives and adopt ortol for bromide prints. Therefore, with a developer that appears to be suitable for negatives, lantern slides, transparencies, and bromide prints, we have every reason to call it "all round."

With most developers, except pyro, it is possible to warm up the tone of bromide prints by increasing the exposure and diluting or restraining the solution; but with ortol this can be done more simply, by leaving out the sulphite of soda altogether and adding just a little more of the other restrainer.

Since writing the first portion of this article I have made some little experiments with regard to the action of the sulphite of soda. The old argument that sulphite is not a restrainer because it can be used alone for development with the reagent, whatever it may be, was the one I wanted to verify or disprove with ortol. I utilised a home-made screen with pieces of paper, each square representing a density of one to sixteen, the first square being a single thickness of paper, No. 2 two thicknesses, and so on up to sixteen.

*Experiment No. 1.*—Two plates were given the same exposure exactly. One was developed with a normal solution of 1 part ortol,  $\frac{1}{2}$  part soda,  $\frac{1}{2}$  part sulphite, 10 grains bromide. The other with the same proportions, but leaving out the sulphite altogether. With both development was continued until square 13 could be just discerned. The result as regards time was that the second plate (without the sulphite) took slightly under half the time of the other; and, as regards gradation, the No. 1 (with the sulphite) was considerably deeper—i.e., more contrast.

*Experiment No. 2.*—Two plates were again used with the same exposure. No. 1 was started in 1 part ortol,  $\frac{1}{2}$  part sulphite, and 10 grains bromide, thus leaving out the carbonate of soda altogether. No image whatever appearing in 30 minutes, the soda was added and development completed. No. 2 plate was treated in the same way, but was allowed to soak for 2 hours, and then no image appeared, and this in turn was developed by adding the soda. The difference in time was not so marked, although No. 2, the plate soaked longest, certainly did take longer to develop. The result, however, as regards contrast, was much the same as the first experiment, that is, the plate longest in the plain ortol and sulphite showed greater contrast.

*Experiment No. 3.*—For this I took three medium rapidity plates, and by previous experiment found out the exposure necessary to get a fair amount of over-exposure, sufficient, in fact, to necessitate the use of considerable restrainer. No. 1 was developed in the normal strength of solution with the bromide increased to 20 grains. No. 2 was developed without bromide, but with the sulphite doubled in strength. No. 3 was developed with both the 30 grains of bromide and the double strength of sulphite. The results showed No. 1 and No. 2 to be as near alike as possible, whilst No. 3 showed greater contrast. In this case I consider Nos. 1 and 2 had each 1 part restrainer whilst No. 3 had 2 parts.

Now, the application of these experiments is to remember that, when using sulphite of soda, to restrain the colour of the image, for that is exactly what it does, it does not alter, it restrains, we are at the same time restraining development in the ordinary sense, and allowance must always be made for this. For instance, with a very under-exposed negative, in order to get the utmost out of it, the matter of colour of the image must be left out of consideration altogether and the sulphite omitted entirely. To take the other extreme, to make the best of gross over-exposure, plenty of sulphite should be used, and, if it is desired to get a brown image in that case by reducing the sulphite, then the bromide must be increased.

I think the foregoing points pretty clearly to the modifications possible when using bromide paper as regards the resulting colour of the print, and I have gone into it rather fully because the effect of the restraining action of sulphite must be then seriously taken into account. Given two equally exposed prints, it would not suffice to leave out the sulphite, in

\* Concluded from page 712.

order to get a brown tone, if the two results are to match as to gradation, for in this case part of the restrainer also has been removed, and must be replaced by an increase of bromide.

For the development of bromide paper I advise the following proportions, viz., 1 part ortol,  $\frac{1}{2}$  part soda, 1 part sulphite, about 20 grains bromide, and 1 part water. For warmer tones, reduce the sulphite and increase the bromide. That is about as clearly as I can put it. I do not imagine that the small quantity of hypo used has very much effect, but, if the hypo solution should be kept separate, by all means leave it out. As to ortol's keeping power with bromide paper, I have already referred to this, and of course I mean a mixed solution. I have repeatedly developed twenty prints one after the other in two ounces of solution, though care has to be taken to drain the prints fairly well before washing in order to avoid unduly lessening the bulk of solution. How often it may actually be used I have not tried, deeming twenty to twenty-five prints a sufficient test for practical purposes.

During the whole time I have used ortol for bromide paper I have never seen the slightest appearance of stain, and I will candidly confess that with no other developer that I have previously used has such complete immunity been my lot, at all events. Staining has always come sooner or later, even when using comparatively freshly mixed solutions.

During the course of the article I have dealt with lantern slides and transparencies as different items, and they are so in one respect, viz., the result necessary to obtain. A lantern slide must be of a certain degree of density to make a good appearance upon the screen, with a fairly powerful illuminant in the lantern. And that degree of density or contrast is considerable. On the other hand, a transparency for reproduction or enlargement can be, and perhaps should be, very much weaker in contrast and a different type altogether. And so, although lantern slides and transparencies are the same as regards material, they differ in treatment to accomplish a certain result. In an article, therefore, the object of which is to treat ortol fairly exhaustively, the difference between these two is sufficient to justify a distinction.

The softest and most delicate transparencies may be obtained with ortol by the omission of the sulphite and dilution of the developer with water; whilst, on the other hand, by setting to work the other way brilliant lantern slides are most easily obtainable, either of a black, warm black, or brown tone. The procedure is practically the same as with bromide paper.

The fact that ortol will give either black or brown deposits, therefore, becomes a factor in lantern-slide making of considerable importance. Not only can we regulate the density but also the colour, and, with these two powers, it is possible to turn out slides suitable for any illuminant. Light does not pass through a brown deposit quite as easily as through a black, even given the same density, if it is possible to gauge density under these conditions without the test of light. I mean if it is possible to say two slides are equally dense without passing light through them, because, as soon as we vary the strength of that light, the relative proportions of a black and brown image will vary.

Now, I know of no other developer that will give such a range of colour with normal exposures. Pyro gives usually warm black tones, whilst others, such as hydroquinone, give grey-black. Neither will give both, as ortol will and does. I am now, of course, speaking in a practical fashion, not of elaborate experiments to get a grey-black tone with pyro. It might be done; I do not say it is not possible, but it would be going out of the way, whereas with ortol one tone is as easy as the other, and easier. There appears to me, however, also a further difference, the brown tone of pyro on a lantern slide is more of a universal stain than an actually brown deposited image. This should make a grey-black colour with pyro an easy matter, only it doesn't.

Leaving, however, some of these debatable matters, there are many subjects that are better rendered in monochrome by a brown or a warm black as compared to the cold grey-black. If we want any proof of this, we have only to remember how often wet-collodion slides are toned to get away from the crudity of the natural colour of the process. Almost all landscapes are truer to nature in a warm tone. We have, of necessity, to translate the rich greens and browns into a much colder tone, but in making them absolutely black we overshoot the mark. We see a slide representing a leafy lane in June, the leaves on the trees all tingling with the warm greens reflected by the sunlight; in the hedgerow are wild flowers, and at the side perchance a rose-covered red-tiled cottage. We have to reproduce all this in practically one shade, black to grey according to density, and clear glass for the white, blue, and lighter colours. A brown tone gives a closer approximation all round.

Of course, this can be overdone. I was once shown a rather striking

group of grimy coal miners leaving work, the foreground being coal dust, with, just behind, a huge heap of refuse from the pit, and coal stacked, whilst for background the blackened coal-grimed shafts and chimneys kept watch and guard. The slide, however, had been toned a rich ferrid-cyanide red, a crude colour fit only for the representation of that place we are occasionally told to go to.

To turn now to the item of wholesale development, I have for many years been an advocate of not only getting development done as soon as possible, but have claimed an advantage in using a large tray and developing as many plates at a time as possible. I have never been able to understand, probably due to my ignorance, where the fun of painstaking development comes in, unless it be necessary. We can do so little with our developing solutions—and that I stoutly maintain—that, after selection, and arrangement, and exposure, nothing interests me until I begin work again on the finished negatives. These delirious little joys we read about of adding two more drops of bromide, or three and a half minims more of accelerator, have never been mine, at least, not for the last twenty-five years or more. Except on rare occasions, development, to me, is merely a necessary evil, it is work, and work only. If my plates would come out of the camera developed, fixed, and dried, ready for working up or printing from, I should be the more pleased. All the loving little titivations we hear of, dabbing, patting, and breathing on the plate, and, in fact, all the little dodges that our photographic penny-a-liners run so frequently through our periodicals, possess no attraction for me. I want the mechanical operations of photography done with as soon as possible, and development, with me, is a mechanical, uninteresting occupation.

How many times I have been attacked for what has been termed slipshod plate spoiling I cannot count; people used to be horrified at my putting six, eight, ten, or twelve hand-camera shots into one dish. A good deal of this horror has now vanished, because it is becoming gradually recognised that that I have maintained for years that we can modify but very slightly in development, and that the safest way is to modify in the exposure. If the worker will trouble over the duration of his exposures, he need not worry his head about development.

No; careful exposure is what is wanted, and then the plates can be developed in a bucket by the bushel.

How many series of plates are exposed at the same time or under equalising conditions? Many thousands. Take the every-day professional: he may have one or two tough jobs, but the best part of his work, he knows, is fully exposed. Even take the amateur with an exposure meter who develops a trial plate; he could put all his others into one dish. Or take the case of making a series of contact lantern slides; how easy it is to get a hundred or so all properly exposed. In fact, in many tasks that we undertake it is the easiest possible thing to get a whole lot of plates which will develop absolutely right in one strength or proportions of a developer. To most of us, whether professional or amateur, such a time comes, and when it does, I repeat, wholesale development gives a better average result.

In my own practice, I find it pays, whenever a large number of prints or slides are required, to arrange the negatives according to density, exposing all first and developing in dozens. I certainly do not lose more than three per cent., and, if exposed and developed singly, I should lose more.

The continuant power of ortol is a great help in wholesale development, as plates can be placed into plain water to continue, whilst others are gone on with in the developer.

In conclusion, I hope enough has been advanced in the cause of ortol to lead to an earnest trial of it by my brother workers.

WALTER D. WELFORD.

NOTE.—As in two makes of a developing agent there may be different qualities, I ought to have stated that all my experiments have been made with Ortol-Hauff.

#### TEACHINGS OF DAGUERRETYPE.\*

THE TRAIL-TAYLOR MEMORIAL LECTURE.—No. II., 1899.

THERE is little doubt, therefore, that iodine was given off under the influence of light in presence of an iodine absorbent. It may be noted that, in all these cases, the parts of the iodised silvered glass that had been in contact with the iodine absorbent surfaces were transparent, while those in contact with the mica showed distinct cloudiness or opacity, though enclosed and protected from the air.

\* Concluded from p. 755.

Scholl then argues that, if the clouding be due to loss of iodine during exposure, it ought to be less or disappear altogether if the plate is exposed in the vapour of iodine. He found, however, that, on the contrary, the plate clouded much more readily under exposure to light in the iodine vapour than it did in the air. The opacity, therefore, is not due to loss of iodine, and the action of the collodion or varnish in hindering it must be due to its preventing the access of air to the film. The change in the iodide must consequently depend upon the nature of the gases in which the plate lies during exposure.

[The occurrence of the clouding in the cases above noted, when the iodised films were exposed in contact with mica, may, I think, be explained on Scholl's theory by the iodine being first given off and then resensitising the film, as if it had been exposed in the vapour of iodine.]

Experiment showed that hydrogen and nitrogen had absolutely no effect in producing the opacity. In oxygen, however, it was produced rather more quickly than in air, and it was evident that oxygen is the active agent in the change.

This being the case, the first question was whether any oxygen compound of silver and iodine is formed—such as silver oxide, iodate of silver, or silver oxyiodide? It was found, however, that the clouded film remained perfectly unchanged in ammonia, and no trace of chloride could be obtained by adding hydrochloric acid. Moreover, the opacity could be produced in the complete absence of oxygen in an atmosphere of hydrogen, which, as we have seen, favours it. In this case the opacity occurred distinctly more quickly than it did in air with the same exposure.

If no oxygen compound is formed, Scholl says, we can only conclude that pure silver iodide is present. That this is the case may be shown by heating an exposed plate which is strongly opaque in parts; both the clear and opaque parts turn of a clear deep yellow, which is characteristic of the change from the hexagonal system of crystallisation to the regular at temperatures over 146° C. (In repeating this experiment I find that the deep yellow colour produced by heating goes off again at once as the plate cools. This is exactly analogous to the deepening of colour of pure iodide in the light, and the return to the original colour I have already noticed.)

In fixing solutions of sodium thiosulphate or potassium cyanide, the film dissolves equally in the unexposed transparent and exposed opaque parts. (The action of sodium thiosulphate is to make the unexposed parts of the film opaque, just like the exposed parts. Potassium iodide has a somewhat similar effect, ammonium sulphocyanide also, but it seems to dissolve the exposed opaque parts less readily than the transparent parts.)

From these experiments Scholl says we may conclude that the opaque film is formed of pure, mechanically divided silver iodide, and that oxygen plays a catalytic part in advancing the formation of an intermediate substance. He considers the reactions caused by the exposure of the silver iodide to be somewhat as follows:—

According to Arrhenius, silver iodide exposed to light is dissociated and its stability strongly affected. For complete decomposition, a substance must be present which can combine either with silver or iodine. In the foregoing case, the silver forms, with the oxygen of the air, a compound, possibly  $\text{Ag}_2\text{O}$ , and the silver iodide will be more easily decomposed by the presence of oxygen. This silver oxide must be again decomposed by light, and the silver set free again forms silver iodide with the free iodine, whereupon the same process can begin all over again.

In this way there must be a continual transference of atoms, which, no doubt, is connected with the loosening and clouding of the whole film. It is unimportant whether  $\text{Ag}_2\text{O}$  itself or another body easily decomposed in light is formed; the essential point is that oxygen, by forming a compound, favours the complete decomposition of the already dissociated silver iodide, and then there is an immediate return to the original state, and a new formation of the silver iodide originally present.

Iodine must evidently, therefore, act more strongly than oxygen. On account of the greater affinity of silver for iodine than for oxygen, a compound which can be split up by oxygen must be decomposed much more readily by iodine. It is thus easy to understand why the opacity takes place so much more readily the greater the excess of iodine the plate exposed to air contains.

The fact that the images produced by the exposure of this pure iodide to light can be developed by mercury vapour or by silver deposited from an acid pyrogallol developer does not require, according to Scholl, to be attributed to a chemical change in the exposed film, but rather to the roughness of the surface caused by the breaking up of the film in the exposed parts, the rough surface more readily taking the mercury and silver. This agrees with my own observations, but I do not think it applies in all cases.

I have gone somewhat fully into these observations of Scholl's in order to make them clear. Whether his theory is correct I cannot say; but that oxygen, taken either from the surrounding air or from the watery vapour which is always more or less present in it, does play an active part in the decomposition of silver haloids in light, has been proved by H. B. Baker (*Trans. Chem. Soc.* 61, 1892, 728).

From experiments recorded in the *Researches on Light*, Hunt came to the conclusion that the first action of the solar ray is to liberate one-half of the combined halogen (chlorine in the cases recorded, but the conclusions apply equally to iodine and bromine), which is very readily, moisture being present, replaced by oxygen. This absorption of oxygen or its combination with the decomposing chloride he proved by placing some pure silver chloride in a bent tube closed at one end while the other was immersed in distilled water. After some days' exposure the water rose in the tube and contained chlorine, which was shown by the usual precipitate with silver nitrate.

That water is decomposed by the action of light on silver iodide is, I think, shown by the following simple experiment. Some of the brick-red powder of anhydrous super-iodised iodide was placed in a tube with distilled water, and then exposed in the sun. After a time it was found covered with little bubbles of gas, most probably oxygen. The iodide became paler in colour, though not lemon yellow, and the supernatant watery fluid gave a slight cloudiness to a solution of silver nitrate. By remaining longer in the water the pale yellow iodide was formed.

Similar little bubbles of gas were observed when precipitated silver was treated with iodine in distilled water and exposed to the sun.

Captain Abney has recorded a similar experiment in which silver iodide was placed in a test tube with a boiled solution of silver nitrate. On exposure to light, bubbles of gas were found collecting in the solid iodide, and proved to be oxygen. From which, he says, we may suppose that the liberated iodine decomposes the water in contact with it (as does chlorine) and produces hydriodic acid and oxygen.

Professor Meldola has also gone into this question in his *Chemistry of Photography*, and seems to think that an oxychloride may be formed by the decomposition of silver chloride by light in presence of watery vapour. This view is confirmed by Baker's recent work, already referred to. From the appearance of the substance produced by the union of silver and iodine under water, and its peculiar olive green colour, it is possible that it may be an oxyiodide or a subiodide, and it may be worth more careful examination than I have been able to give it.

In an earlier part of the lecture it was stated that iodine has a very much greater affinity for oxygen than the other halogens have, and so it seems not unlikely that oxygen may produce more marked effects upon iodised silver plates by the action of light than it does with the chloride or bromide.

I have noticed other effects in the opaque parts of these films which seem to be due to the formation of some gaseous product, but further observation is necessary, the tearing up of the film can, however, be readily seen on two plates I have here. Another plate exposed in contact with a gelatine film negative does not show it, but rather a great increase of density.

That there is an evolution of a gaseous product during the exposure to light in contact with air of these superiodised plates is demonstrated by the blister-like appearance visible in the exposed parts. Moreover, on exposing one of these films in contact with a silvered glass plate not only was the surface of the silver darkened in the parts exposed to light through the iodised film, but minute black spots were produced on the silver corresponding exactly with the blisters, as you will see. The composition of the dark spots remains to be seen, but they were most probably caused by iodine expanding and bursting through the film. This effect has not been noticed by Scholl.

If Scholl's theory of the catalytic action of oxygen be correct, and this action takes place when haloid salts of silver are exposed to light, even without the presence of organic matter, it will probably also take place, but in a much greater degree, when organic matter is present. When oxidation takes place in presence of water or watery vapour Schönbein has shown that peroxide of hydrogen is formed, and, more recently, Sonstadt has traced its presence, when chloride of silver is exposed to sunshine in water (*Proc. Chem. Soc.* 14, 1898, 179). This substance, as we know from Dr. W. J. Russell's recent researches, is capable, even in very small quantities, of producing the developable state of the haloid salts of silver on an ordinary gelatine dry plate. In this way, therefore, we may possibly be able to trace the connexion between the effects produced by peroxide of hydrogen vapour and by light upon the haloid salts of silver. Further investigation is, however, required.

I hoped to have been able to say something with regard to the action of light upon the ordinary Daguerreotype plate, and had intended to almost confine myself to the question of the probable nature of the latent and printed-out images upon iodised silver, but, as I went on and my attention was diverted to the points I have brought before you, I have not been able to complete the work I began. I propose, therefore, to close my lecture here and defer further consideration of the question till I can work it out at leisure and give the results to the Society in a supplementary paper.

The points I have dealt with are none of them new, but are, I think, of some interest generally, and I hope I may have been able to throw light upon them and carry on the work of my predecessors.

MAJOR-GENERAL J. WATERHOUSE, I.S.C.,

Hon. Secretary, Royal Photographic Society. ♀

## FOREIGN NEWS AND NOTES.

**Ferric Oxalate for the Platinum Process.**—Herr Gaedicke has worked out the following method of preparing this salt, and publishes it in the *Photographisches Wochenblatt*. To prepare half a litre of ferric oxalate solution of the strength required for the platinum process, take 30 grammes of iron wire, polish it with glass paper to free it from dust, place it in a porcelain dish with 150 c. c. of nitric acid, and heat it over a spirit lamp. At a certain temperature there will be violent ebullition, and red fumes will be emitted in considerable quantity. Avoid their effects by placing the vessel out of doors. If all the iron is not dissolved, add more acid. A thick, dark brown liquid is thus obtained, with a small precipitate of carbon, which is of no importance. Pour the brown fluid into another vessel containing 150 c. c. of strongest ammonia (sp. gr. 0.91); stir up the dark brown paste with a glass rod, and, if necessary, add more ammonia until it smells strongly of the same. Be careful to avoid waste, otherwise the final solution will be too weak. Dilute the paste with a little water and pour it into a 5-litre bottle. Make up the quantity to 4 litres with water, cork the bottle and well shake it. After it has stood for five minutes, gently lower the bottle on to its side with the neck projecting beyond the edge of the table, and let it rest five minutes longer. The brown precipitate will sink below the level of the neck, and the cork should then be slowly withdrawn to allow the water to escape. This process of washing by decantation should be repeated four times, and the bottle should be allowed to stand half an hour after the final washing to permit the removal of as much water as possible. After draining the precipitate, add 110 grammes of oxalic acid in crystals (fresh). This and subsequent operations should be done by artificial light. Stir or shake until completely dissolved, but avoid heating the preparation, as it would then decompose. The yellowish-green fluid should be filtered to remove the carbon, and kept in absolute darkness. If there is less than half a litre, make it up to that quantity with water, but the yield is usually about 600 c. c. In the latter case there will be only 17 instead of 20 grammes of ferric oxalate per 100 c. c.

**Voigtlander & Sohn, Brunswick.**—We learn that Dr. Hans Harting, formerly with Messrs. Zeiss, of Jena, has joined the board of management of Messrs. Voigtlander & Sohn. He succeeds Dr. Miethe, who was recently appointed Professor of Chemistry and Spectrum Analysis at the Technical High School, Berlin.

**Filter Papers.**—The *Deutsche Photographen Zeitung* mentions that, if filter papers are immersed in a bath of nitric acid (sp. gr. 1.42) for a short time, and then well washed with water, they remain porous, and will not tear when used for filtering warm solutions.

**Surgery and the Cinematograph.**—The eminent French surgeon, Professor Doyen, exhibited in July at Kiel, before a select audience of scientific men, a number of cinematographic representations of surgical operations. The descriptions given in text-books are necessarily incomplete, and it is difficult for students to follow all the details of an operation in the hospital theatre, but the cinematograph affords an opportunity of recording an operation in such a manner that it may be followed at leisure and repeatedly. The representation was regarded with great favour from an educational point of view.

**Flashlight Accident.**—We read in the *Deutsche Photographen Zeitung* that an unfortunate man named Stückrad lost his life recently at Maffersdorf in attempting to photograph by means of magnesium flashlight. The powder was placed in a tube, but, in taking breath to project it through the flame of a lamp, he drew the ignited charge into his mouth. His jaw was shattered and he was instantly killed.

**Poisons.**—Edward Crouzel, in the *Chemiker Zeitung*, recommends the following remedies for first help in case of poisoning, when the cause is unknown: Give half-gramme doses of tartar emetic in hot water at short intervals. Make the person drink cold milk to which five per cent. of borax has been added. The milk will tend to protect the walls of the stomach and the borax form insoluble compounds with mineral bases. To counteract collapse, give a mixture of concentrated cold coffee and Peruvian bark in equal quantities, with a little sugar and a few grammes of Hoffmann's drops. A solution of albumen may be used instead of milk. A doctor should be fetched immediately, and these remedies used meanwhile.

**A Spotting Medium.**—The *Photographische Chronik* mentions that an excellent medium may be prepared by scraping away the dense portions of old negatives. When a sufficient quantity has been secured, place it in a small bottle, add a little water, a few drops of acetic acid, and dissolve by means of heat. A thickish paste is thus obtained, which has the same properties as the negative, and which is easily used with the brush. The paste may also be prepared from the cuttings of toned prints.

**The Pictorial Post Card.**—The *Progrès Typo-Litho* draws attention to the enormous development of this industry. At Frankfurt a/M, 12,000 hands are employed, and it is estimated that 100 new designs are brought out every day in Germany. Reckoning that 1000 cards of each sort are printed, the annual production must exceed 30,000,000. Most of the cards printed in Germany are exported to Austria, Italy, England, France, Sweden, Russia, South America, and Australia.

**A Durable Ferrous-oxalate Developer.**—Dr. Hauberisser, of Munich, has been making a series of experiments as to the action of certain additions to the ferrous-oxalate developer, and finds that the following gives the most lasting developer:—

1. Neutral potassium oxalate .....	500 parts.
Hot distilled water .....	1500 "
2. Ferrous sulphate .....	200 parts.
Distilled water .....	600 "
Sulphuric acid .....	g. s.
3. Rochelle salts .....	20 parts.
Water .....	100 "
4. Potassium bromide .....	10 parts.
Water .....	100 "

For use, add 5 parts of No. 2 to 1½ parts of No. 3, and boil, and, whilst hot, add to 17½ parts of No. 1. For stand development, the above should be diluted with from 100 to 200 parts of water.

**Orthochromatism and the Characteristic Curve of a Plate.**—Dr. Eder points out, in the *Photographische Correspondenz*, that we understand by the term characteristic curve the dependence of the blackening on the exposure, that is to say, in what way the blackening increases as the exposure increases. With white, or blue, or violet light the course of this curve is usually regular, that is to say, with increasing exposure the blackening also increases to a very high limit. This, however, is not the case with many orthochromatic plates by red, yellow, or green light. It may here happen that small quantities of light may produce a deposit, and this may increase to a certain amount; then, however, it will remain almost constant, although exposure is increased. This is the reason why many plates when tested in the spectroscope may prove to be very sensitive, and yet give no good results in practical work. Spectroscopic tests are therefore insufficient, the whole course of the characteristic curve must be determined by coloured light.

**Balagny's Silver Intensifier.**—This is given in the *Bulletin de la Société Française*:—

1.	
Sodium sulphide .....	25 parts.
Water .....	100 "
2.	
Silver nitrate .....	5 parts.
Water .....	100 "

No. 1 is dropped slowly into No. 2. The precipitate first formed is redissolved on further addition of No. 1. The negative is placed in this till bleached, and well washed and redeveloped with any developer.

**Another Three-colour Process.**—According to Dr. Neuhauss, the very best results which he has seen in trichromatic printing have been obtained by Herr Hofman who uses the ordinary method of taking the three negatives, but has discovered how to make carbon tissue in the three requisite colours. Neuhauss states even very large sizes can be worked, and that there is no difficulty of registration, and that paper prints are as brilliant as transparencies.

**To Clean Nickel.**—The *Photographische Chronik* recommends a bath of 2 parts of sulphuric acid to 100 parts of alcohol. Immerse the articles in the bath for a few seconds, rinse with water and dry them. They may be polished in the usual manner.

**A New Reducer.**—Professor Namias suggests the following as a new reducer which will keep well, and obviously does not require the negative to be absolutely free from hypo:—

Potassium permanganate .....	1 part.
Sulphuric acid (strong) .....	2 parts.
Water .....	2000 "

The dish must be continually rocked whilst the reduction is taking place, and the solution cannot be used over again. If the gelatine is stained brown, it can be removed by bathing in a one per cent. solution of oxalic acid. The above solution, when made double the strength, may be used to produce *contretypé*. The negative should be fully exposed, and developed with a hydroquinone developer rich in bromide as long as possible without producing fog; the negative should then be rinsed well, and immersed in the permanganate solution, when the image will dissolve, leaving the silver bromide unaffected by light intact, and this, after exposure to light, may be developed in open daylight, and the following should be used:—

Metol .....	10 parts.
Sodium sulphite .....	40 "
Potassium hydrate .....	10 "
Water .....	1000 "

#### OZOTYPE AT THE CAMERA CLUB.

THE march of events is such a quick march, and so many photographic events are crowded into the short space of eight months, that many are apt to forget the particular items of photographic advance which happened so long ago as the month of March; but, if the inquirer will take the trouble to overhaul the journals of that date, he will find that in that month Mr. Thomas Manly read a paper at the Royal Photographic Society on a new printing process, which he called Ozotype. Mr. Manly has much improved this method of printing, and he last week demonstrated the nature of the process at the Camera Club.

Ozotype may be described as resembling the carbon process, while at the same time it is distinct from it. Carbon tissue of the ordinary kind is employed, but it is not sensitised, while at the same time its carbon is used to build up the image. As Mr. Manly was able to show the entire process, from the preparation of the paper to its final appearance as a picture, we cannot do better than to follow his manipulations in detail.

A sheet of Rives paper is pinned to a horizontal board, and a couple of drachms of sensitising solution—the operation taking place in full daylight—is poured into the centre, and worked all over its surface with a broad hog's-hair brush. The exact nature of this solution is at present a secret, and further than that it contained a bichromate and a manganous salt Mr. Manly did not describe its composition. It can be bottled off, and will keep indefinitely. The paper so prepared is hung up to dry, and, provided the paper be of a pure kind, it will keep when dry for several days. It is exposed under a negative in the usual way, and seems to be about as sensitive as platinum paper. It may be noted that the image which becomes visible in the printing frame is not unlike that afforded by platinum. When printed, the paper is washed until all soluble matters disappear, when it can be dried and kept for any reasonable period before being submitted to the next stage of the operations.

This consists in pigmenting the image by associating it with a sheet of carbon tissue of the same size as the print. Note that, unlike the carbon process, the tissue does not come upon the scene until exposure has been completed without its aid.

To accomplish this purpose, the print and the tissue are placed together in a tepid bath, consisting of water, 40 ounces, to which has been added 50 minims of glacial acetic acid, 30 grains of quinol, and a drachm of glycerine. After a couple of minutes' immersion, the two sheets are withdrawn together and squeezed face to face. They are now hung up and dried.

When dry, the print, with its tissue adherent, is placed to soften in cold water, and is then developed in a hot bath, just as if it were an ordinary carbon print. The colour oozes from it, and it is laved with the hot water as soon as the tissue leaves it. It is here that control over the print comes in, for excess of washing will dissolve away all the colour and leave nothing but blank paper. While this washing operation is going on, the print is laid upon a sheet of zinc which lies ready for it in the hot bath. Treatment with weak alum solution completes the operation, and the print can then be mounted on cardboard in the usual way. Mr. Manly showed the entire process from beginning to end, by means of prints which he had ready to take up at its various stages from point to point. He also showed a large number of finished and mounted pictures, which the members present could examine at their leisure. Some of

these prints were extremely good, but it would have been as well if the lecturer had had other prints, from the same negatives, by a standard process, so that his auditors could have compared the two. We say this, because, in some cases, it was not clear whether faults were traceable to the process or to the negatives from which the prints were made.

Mr. Manly concluded his demonstration by showing some very interesting experiments with unpigmented ozotype prints. In the first of these he took a print, and, placing it in a dish, poured upon it a solution of aniline hydrochloride, made strongly acid with sulphuric acid. The print under this treatment gradually acquired a fine green colour. By further treatment with ammonia this changed to a rich purple. Taking now the original aniline solution, and adding to it a proportion of a two per cent. cupric chloride solution, and applying it to a fresh print, the latter turned bright blue. It was suggested by a member present that possibly such a method of colouring might be applied to lantern slides, and the lecturer said that there was no reason why such an application should not be successful.

The Rev. F. C. Lambert, who occupied the chair, said that the Club ought to congratulate itself upon passing an evening in such a practical and pleasant manner. Such a paper, combining as it did both theory and practice, was a model one for a club of photographic workers. The usual vote of thanks closed the proceedings.

#### ON PRINTING IN CLOUDS.

How often is it, when a landscape has been selected and the lighting proves satisfactory, that the expanse of sky which demands inclusion is beautified by the presence of varied forms of clouds which are requisite to set off the picture? And, even when the photographer is fortunate in viewing above his selection a charming crown of light, fleecy clouds, with what frequency is he successful in securing them on the same plate as the landscape without sacrificing the latter by under-exposure for the sake of retaining the clouds? Thus generally in the simple finished print the sky is a blank, uninteresting, white expanse, which is so fatal as to prove quite sufficient to discount any beauty which may exist beneath its canopy, and destroy what might otherwise be a picture. On the other hand, with suitable clouds, often a very ordinary photograph can be so improved as to really merit the higher title of "picture," notwithstanding that it may still have its weak points.

Somehow or other, numberless amateurs, even those who would indignantly repudiate the designation "tyro," seem to have got it into their heads that to print in clouds is a feat quite beyond their powers of performance, and, despite every assurance to the contrary, they will persist in believing that it is on a par with the Labours of Hercules; and so still their prints are finished with their ghastly white skies, and not even an attempt is made to sun down the most glaring.

At least, why will not the P.O.P. printer try what he can make of printing in a cloud or two? "Nothing beats a trial" is a wise maxim, and one which the fatalist in photography would do well (*pictorially*) to take to heart. Certainly, printing clouds in platintypes, bromide, carbon, and other unseen, or comparatively unseen, printing processes is a more formidable undertaking, but even here a little care will accomplish much, as the writer hopes in due course to show.

But first to generalities. The landscape or pastoral photographer should be as keenly on the outlook for pictures overhead as for those more on a level with his eye. Readers of this paper have so often obtained full instructions in taking cloud negatives that it is only wasting valuable space to repeat them here. The writer, at the outset of a career photographic, endeavoured to print clouds in half-plate prints from half-plate cloud negatives, proceeding in the orthodox fashion, using the back of a printing frame to support the print and negative over it, and holding the whole in the sun (or apology for it) during the entire operation. In cold winter weather, with the sun in hiding, it was quite an heroic undertaking to stand at the open window and shiver, with fast freezing fingers, for a period of time varying from fifteen to thirty minutes until the clouds were "done." Nor, apart from this drawback, was the method satisfactory. Where the view was taken horizontally, whether the clouds fitted in well or no, there was no choice, the sky negative, being of the same size as the print, of necessity could only be placed squarely over the print so as to cover it entirely—this obviously; and yet often the clouds were not desirable in the place where they coincided with the print.

Though this disadvantage disappeared when a vertically taken landscape print was placed under a horizontally taken cloud negative, there was the awkwardness of shading the lower portion of the photograph, necessarily uncovered by the cloud negative, from the light. Again, in both cases, when the light was bad and printing prolonged in the frequent compulsory examinations of the print, either negative or print was very apt to slip and double printing result. A way out of all these troubles occurred to the writer, and that by utilising whole-plate cloud negatives for printing into half-plate prints. Printing was then done in a whole-plate printing frame, when all previous difficulties and annoyances at once disappeared. The advantages accruing from this plan were enormous, and should be obvious to every one. Hands were free, and there was considerable choice in the available expanse of negative of that

part most suited to the particular print. Of course, initially, some extra trouble is involved, but it is more than repaid in the subsequent ease of procedure, &c., it affords. From the original cloud negatives first of all are made transparencies. To the lantern-slide maker this will present no difficulties, but others may prefer to use the useful Novitas stripping P.O.P. (most simple to use), and transfer these prints to glass. From these, enlargements to double the diameter of the prints to be "clouded" are made; that is to say, quarter-plate prints will require a half-plate cloud negative, and half-plates a whole-plate negative. Each individual must decide for himself what he will make the medium of his enlargements—whether he will use films, plates, or Wellington negative paper. Films, though, of course, the most expensive, are undoubtedly the best for the purpose, since they can be printed from either side, and celluloid, being almost as transparent as glass (the cloud image in any case being thin), the landscape print, when fastened down in the frame, will show through the negative very clearly—quite a necessity for exact masking. While the Wellington negative paper has the great merit of being the cheapest and at the same time a very excellent material, which, like films, can be used either side up in the frame, yet necessarily it has not the same degree of transparency, which, for our purpose, is the great advantage of the former, and even when a very thin negative is made thereon, and, with a very bold print underneath, it is seldom that the outlines of the latter can be distinguished through the negative in the same way as through films; not, indeed, unless it be held up to the light, which, for the purpose of adjusting masks, is seldom practicable. Plates, in price coming between films and negative paper, can, of course, only be printed from one side, this constituting their drawback; but, of course, they print as expeditiously as films, which is not the case with negative paper, though the latter is astonishingly grainless.

For those who have never used this paper, and think of trying it for this purpose, it may be remarked that its manipulation presents no special trouble, being almost identical with the working of bromide paper. However, whatever material be used, metal is the developer recommended to secure a nice soft, thin, quick-printing enlargement, full of detail, and such a one any amateur who can enlarge should find no trouble in making. Of course, where enlarging is not done, these could be made professionally from the amateur's negatives if it were desired. If the sky does not fill the entire enlargement (which will seldom be the case, since, in enlarging, due care must be taken to preserve a certain proportion between the clouds and the size of landscape with which they will be used, or the combination will be absurd), the rest should be rendered quite opaque (either with some blocking-out medium or paper) to protect any part of a print which may rest upon this portion. It should hardly be necessary to remark that, if films or paper negatives be used, the printing frame will require a piece of clean glass in it on which to support the flimsy material. Before the actual printing is touched upon, it cannot be too firmly impressed upon the cloud-printer that it is essential, that some sense of fitness should be shown in the selection of clouds for each negative, that due and full regard should be given to the lighting and character of the landscapes into which they are to fit. The reader may laugh at this word of caution, but it is a necessary one, for the reader has seen a smiling summer landscape, obviously taken in sunlight and without a suspicion of a heavy sky, actually finished off (in more than one sense) with threatening storm clouds; and, again, buildings strongly lighted from one side crowned with clouds as strongly lit from an opposite direction! So, good readers, beware of such anachronisms.

Before starting upon the cloud-printing it may be necessary to cut a mask to protect the landscape or building if the sky line be very delicate or irregular, but very often such a special mask is unnecessary, and simply one or two pieces of cardboard (like those found in packets of printing paper) will serve the purpose; but, if a special mask is necessary, the best way to secure one is to paste down a waste print on a bit of card, and carefully cut away the sky. Next select a suitable cloud negative from your store, and place your print requiring a sky in position upon the most suitable portion of the chosen negative. Then, after fastening down the back, the mask can be laid over the part with which it coincides, the adjusting of which is quite a simple matter, as the picture should show through the cloud negative. The mask placed, the frame can be put out in the sun, but this necessitates keeping the shade moving all the while to obviate a palpable join; but, if the frame be left by itself out in the shade, beyond an occasional examination of the print and moving of the mask just an atom higher or lower, there is no need to stand over it—a great convenience. With platinotypes whose faint image is difficult to discern under the negative, and still more so with carbons and bromides, where there is no visible image, cloud-printing is not quite such plain sailing, as obviously the mask is not so readily adjusted. Therefore, using these papers, as a print with an only too wide join between landscape and sky, is a "waster," it behoves the printer to take especial care, since such faults do not come to light until the prints are developed. In printing clouds in carbon tissue, of course, some guide to the action of the light—some actinometer—is essential, and is also desirable in the case of platinotype. The best plan is to use on a spare part of the negative an unprinted trimming of P.O.P.

In both cases, when this is printed to the depth desired in the finished print, its companion can be safely assumed to be finished too. As a

guide to the accurate placing of the mask, the back of the print should be covered by a large-sized piece of white paper, which will show up the guides for the arranging of the mask, which guides are to be presently cut. Before the print be taken off the landscape negative, open each half of the back in turn, and, raising the print exactly where the sky line begins, cut out a nick in the edges. These, thanks to the white paper, will clearly be seen through the cloud negative, and will serve as guides to accurately adjust the mask. But let it be noted that, where many prints off one negative requiring clouds or an enlargement from such are to be made, it is far less tedious to make one satisfactory print of landscape and clouds on Novitas P.O.P. and transfer it to glass, whence a combined negative, saving all further trouble, is secured. It is hoped this paper will help some photographically "lame dogs over a stile;" if so, it has not been penned in vain.

SEMPER EADEM.

#### HOW TO MAKE A TWIN-LENS FOCUSING HAND CAMERA.

No doubt many readers on seeing this title will at once come to the conclusion that the making of such a camera is beyond their powers. I trust that any such will believe me that it is not at all a difficult matter, and that, if they only follow the instructions, they will find themselves in possession of a very serviceable hand camera.

As a twin-lens camera must necessarily be larger than a single-lens camera, it is necessary to use as light a substance as possible. I therefore selected millboard for the interior of the camera, and shall now proceed to state the *modus operandi*.

We will first make the camera box (fig. 1, A). To do this, take a piece of millboard 4 inches wide by 16 inches long. Rule lines across at  $4\frac{1}{2}$ ,  $3\frac{1}{2}$ , and  $4\frac{1}{2}$  inches respectively, and, with a sharp knife, cut nearly through, but not quite. Fold the millboard over in these cuts, and, by gluing the two ends together, we get the four sides of our camera box. Next take another piece of millboard the same size, cutting and folding as before. This latter is for the finder, and should be glued to the top of the camera box (fig. 1, B).

We next require two pieces of millboard, about  $5\frac{1}{2}$  inches by 9, for the front and back of the camera box and finder. I have given these measurements rather larger than is actually required, any surplus can be cut away later on. Glue these two pieces to the back and front, leaving about

a quarter of an inch at the bottom. This should be done very carefully, so that no light can creep into the camera box. I found some old mackintosh cut into strips answer the purpose very well. Now cut a hole in the back of camera box  $4\frac{1}{2}$  by  $3\frac{1}{2}$  inches (fig. 1, C), and, in the front, a hole about 2 inches square (fig. 1, D). Next cut a hole 2 inches square in front of finder (fig. 1, E), and on the top cut one about 4 by 3 inches (fig. 1, F).

Before proceeding further, it would be advisable to decide on the size of the dark slide we intend using, as we can then cut away any superfluous millboard. Place the dark slide chosen on the back of the camera box so that it is in exact register with the hole,  $4\frac{1}{2}$  inches by  $3\frac{1}{2}$  inches, that has been cut out. Mark this on the millboard, and then cut away any from the sides that is not required. Get some pieces of velvet or plush, and glue over the back of camera box where the dark slide comes, so as to keep any light from creeping in.

We will now proceed to make the focussing arrangement. Several methods may suggest themselves; but, as I am giving my own experience, I will state the arrangement that I adopted, and which has given every satisfaction. Moreover, it has the advantage of cheapness.

In fig. 2 I have made a rough sketch of the focussing arrangement. A is a board to which the lenses are attached. It is advisable to make it the full size of the inside of camera case, as by so doing it helps to keep the light from the camera box, and also hides any defects in the making of same. B is a piece of wood about 3 inches long by about  $1\frac{1}{2}$  inch wide, and about  $\frac{1}{2}$  inch thick. This is fastened to the focussing board with two small brass brackets; see that they are at right angles, or otherwise the two lenses, when in position, would not be exactly in register. C C are two pieces of wood the same thickness as B, but which need be only about 2 inches long. These are screwed to the bottom of our camera case, so that B will slide up and down easily between them. In order to keep the board upright, a small brass plate, D, should be screwed to C C.

As the two pieces of wood, C C, must be fastened in the correct place on the bottom of camera case, it would be as well to fasten them in position now. The case can be made of any kind of wood, the lighter the better. Unless the reader is very clever with his tools, I should advise him to use any light wood, and cover it with leather. However, whatever kind is decided upon, take a piece about  $6\frac{1}{2}$  inches wide by 9 inches or 10 inches long. Place the camera box on this, allowing about  $1\frac{1}{2}$  inch at the back, according to the thickness of the dark slide. Cut away sufficient of the millboard at the bottom of the front of camera box to allow the pieces of wood, C C and B, to go under. Mark the position of C C, and screw them on the bottom of case so as to allow the piece, B (to which is attached the focussing board), to slide smoothly backwards and forwards. Now

Fig. 2.

get what is termed a T screw and milled head, which can be purchased at any maker of camera fittings. Make a hole in B to admit the T screw, sinking the T piece in the wood (fig. 2, r), so that when in position it will slide easily with B under brass plate, D. Make a slit in the bottom of camera case between C C, about two inches long, to allow the T screw to come through; screw the milled head outside on to the screw. If this has been carefully done, the focussing board can be moved backwards and forwards, and a turn of the milled head will tighten and hold in position.

We will now connect the focussing board with the camera box. This connexion must be absolutely light-tight, and we must purchase or make a small piece of bellows. The stretch of this will depend on the focus of the lens we intend using. The distance from the back to front of camera box is 4 inches. This, with the velvet at the back and the small piece of bellows connexion, would make the distance about  $4\frac{1}{2}$  inches to  $4\frac{3}{4}$  inches. Presuming the focus of the lens to be 5 inches to  $5\frac{1}{2}$  inches, we shall only require a stretch of about 2 inches of bellows. Glue this to the focussing board and to the camera box. Should a wide-angle lens be chosen, the millboard of which the camera box is made should be cut in the first instance 3 inches instead of 4 inches. For general work, however, a lens of 5-inch to 6-inch focus will be found more useful.

The finder can be connected to the lens board in the same manner by a small piece of bellows, but, if the board is made the full size of the interior of the camera case, this is not necessary, as any little light creeping in may be discarded, as it makes no appreciable difference in the brilliancy of the picture on the finder. Should, however, a smaller lens board be chosen, it would be imperative to use a small piece of bellows.

We will now finish the finder. Get a piece of looking-glass about  $4\frac{1}{2}$  inches wide by 5 inches long; place this in the box opposite the lens at an angle of  $45^\circ$ . Now get a quarter-plate focussing screen, and place over the hole cut out on top of finder. Before fastening these permanently in position, see that the image on the finder coincides with that in the camera. Fasten the lenses in position on the lens board. Now

place a piece of ground glass in the dark slide, drawing both shutters; place this in position at the back of camera box, and focus on some object. Now look at the finder. If everything has been carefully done, the image should be perfectly sharp and coincide with that in the camera. If it is not so, alter the position of the ground glass or looking-glass until they agree. Having done this, glue the glasses in position, and the interior of the camera is complete.

We will now put on the sides of the case, the bottom being already done with the camera in position. Place the sides close up to camera box, having previously cut out a piece from one side to allow the dark slide to be inserted and withdrawn. Fix these sides in place by glue or screws, place the dark slide at the back of camera box, and cut a piece of wood to fit exactly for the back of the case.

As it is necessary for the dark slide to fit close up to the camera box, fasten two springs on the back of the case so that, when it is placed in position, the springs will press against the edges (not the shutter) of the dark slide. Before putting the top of the case on, mark the place where the ground glass of the finder comes, cut this piece out very neatly, as it will serve for the lid of the finder. Now place the shutter on the lens and rack it out to the fullest extent required. Place the door in position and fasten with hinges, having previously cut out the holes opposite the lenses. Saw or plane away any superfluous wood, and the camera is complete with the exception of being covered with leather. I have not gone into every minute detail in this article, as I have concluded that any one deciding to make such a camera would not require every little detail and measurement given, but I trust I have made it clear enough to enable any one to turn out a very serviceable camera; I have had mine in use now for some years and am quite satisfied with the results.

J. H. BURKE.

#### ROOM FOR IMPROVEMENT.

DURING the last five-and-twenty years photography has admittedly progressed wonderfully. We can hardly desire much advance in the quality of our plates and paper, except perhaps in their keeping properties; our knowledge, too, of their manipulation is almost scientifically exact; but our studios, at least, still bear a remarkable resemblance to those of that blissful period when the public cheerfully mounted six flights of stairs to obtain *cartes-de-visite* at two guineas per dozen, and were not so hard to please as they are now.

The photographer, even in these days of enlightenment, still buries his head beneath that awesome black cloth, the terror of children, or, possibly, a potent source of smiles and unseasonable mirth. Then, what unnecessary waste of time is involved in the removal of the focussing screen, the insertion of the slide, and the withdrawal of the shutter. When is some inventive genius going to give us a studio camera with some sort of full-sized finder, giving the picture right side up, and enabling us to have the plate in position, with slide drawn, ready for immediate exposure directly the aspect of things satisfies our critical taste? Then no more will any sorely worried camerist get his shutter withdrawn only to find that the sitter has moved entirely out of position since he focussed him, her, or it—a thing which really does happen sometimes, to the great enrichment of the English language. Only think how we might seize baby's prettiest looks at the very moment, or record for ever the special characteristic of my lady's pet if we only had that camera! Of course, we already have twin-lens arrangements, but only of a small size. If their principle could be embodied on a suitable scale without making the affair materially larger, possibly obtaining the additional image by means of some reflecting arrangement, thus needing but one lens, we should at once be in possession of the suggested improvement.

Again, our cameras might be made much lighter. When is the day coming that we shall have, say, a  $15 \times 12$  outfit, perfectly firm and rigid, suitable either for field or indoor use, and not necessitating a porter to carry it for us? What Elysian times those will be! Larger pictures will then be seen at the exhibitions, and the frame-makers will be in clover. No doubt, glass plates will at that period be superseded by a perfect film, at a lesser cost, and dark slides, in all likelihood, by a featherweight changing box, available for perhaps a hundred exposures.

Then that focussing screw. How long are we going to fumble blindly for it in half a dozen impossible directions, or turn a curious barrel-organ sort of handle at the back, which often obstinately refuses to budge—of course, when you most want it to? Surely our mechanical skill should be equal to the task of devising something more rapidly adjusted and accessible.

Our lenses, too, so exquisite in definition, such perfect products of the highest optical research; but, oh how heavy, and how bound down we are, within limits, to one definite focus, unless we attempt the risky experiment of changing the combinations! What a blessing it would be if we could have a lens available for almost any purpose, with varying focus, easily and accurately adjusted by means of a scale attached to it; one that we could use for interiors, groups, architecture at close quarters, copying, enlarging, or ordinary portraits, so that we need not get rid of all our cash in the purchase of half a dozen different lenses. It seems impracticable now, but so did wireless telegraphy twenty years ago.

When heavy cameras and fittings vanish, they will take with them their present clumsiness and ugly stands, with those creaking and tiresome levers

and screws; something more graceful and ornamental—movable by a touch of the finger from place to place—will have entered the region of actualities. There is not much to be said on the subject of backgrounds, furniture, and accessories that has not already been well thrashed out. The day of cruelly stiff and wooden posing chairs, rustic seats, balconies, &c., is practically past, and, if a man now uses an inartistic or inappropriate setting to his picture, he has no one but himself to blame—indeed, the time of total emancipation from these things approaches. But does not the very form of the studio itself admit of considerable modification? If the "painters' light" has proved itself generally inadvisable, and it is found undesirable to make our *ateliers* as much like ordinary rooms as possible, as some are now loudly preaching, why need they always resemble a sort of glorified greenhouse, without the beauty of its flowers, and ten to one far from waterproof? When shall we be rid of our complicated array of blinds and curtains, whereby we fondly imagine we regulate the light to a nicety, and on the management of which no two photographers ever seem to agree?

And when the day wanes, or the dark foggy season arrives, are we yet in possession of the perfect artificial light, equal in effect to the solar rays? Some will aver that their favourite illuminant, be it the arc light, electric incandescent, acetylene, or some modified form of coal gas, is quite equal to daylight. The fact, nevertheless, remains—whatever a few specially skilled workers can accomplish, the generality of portraits taken by artificial light are by no means up to ordinary standard; there is a certain glare, a nameless imperfection, about them that the sitters themselves are the first to recognise. No doubt, the science of the future will bestow on us that ardently wished-for desideratum, an easily managed and steady illuminant, really bearing comparison with the light of day, and so inexpensive that we may use it to do our printing by when the sun is conspicuous by his absence.

Turning from the studio to the dark room, Mr. Howard Farmer seems about to give us cause to change the name of that indispensable, if generally uncomfortable, place; and there is now really no excuse for our slopping about—working emphatically by faith rather than by sight—in a gloom that rivals the shades, and bemoaning the pertinacity with which that glass graduate keeps getting broken. By the way, why cannot our measures be made of some unbreakable material, as celluloid, *papier-mâché*, or vulcanite; surely this is not difficult?

There have been, as is well known, several distinct improvements in our developing dishes, and other little matters tending to our greater comfort when engaged in compelling the latent image to make itself visible. Chemical research has also kindly placed at our disposal a large array of new developers, each supposed to be better than the last, but all bearing a strong family likeness, and unreasonably lengthy names. We are still, however, crying in the wilderness for that ideal developer which shall do anything we want it to—adjusting itself, without modification, to the given exposure so amiably that we may obtain a good negative under almost any circumstances, thus making over and under-exposure absolute terms of the past. Let us not call it impossible; no man can tell what another decade may bring forth—perhaps even that elusive mystery of the composition of the latent image may be unearthed and proclaimed from the housetops. Perhaps—but let us speak with bated breath—some practicable system of colour photography may by then have made the fortune of its lucky discoverer, after convincing and rejoicing a too incredulous world!

These remarks are far from being made in any carping or ungrateful spirit. We have indeed to be thankful for much that our predecessors dreamed not of. Credit unlimited should be, and is, ungrudgingly given to the persevering men of theory, who have lived laborious days, adding richly to our knowledge of the chemical, physical, optical, and mechanical aspects of our art-science; and to the no less assiduous men of practice, who have given us the excellent and beautifully finished apparatus which we get along so well with that there is some danger of our fancying that the climax has been reached, forgetting that the higher we aim the more we attain to. It, of course, goes without saying that, given the most perfect tools humanity could wish for, the master hand of the skilled artist is necessary to the production of satisfactory work; but, if it is true that the expert, with meagre outfit, can surpass the incompetent or inexperienced, be they never so well equipped, it is still more an obvious fact that the former, unhampered by any petty mechanical hindrances, has a double chance to give his art full and untrammelled play.

A. LOCKETT.

#### CAMERAS FOR COLOUR PHOTOGRAPHY.

MR. T. R. DALLMEYER'S mirror camera, for use in colour photography, is so described in the inventor's patent specification:

I employ a movable mirror for successively diverting the beam of light from the lens to a number of sensitive plates.

I employ a mirror fixed at an angle of  $45^\circ$  to a shaft co-axial with the lens, so that by turning the shaft the image is successively directed on to plates at the sides of the camera.

Fig. 1 is a back elevation, and fig. 2 a longitudinal section of the apparatus.

Fig. 3 is a longitudinal section of a modification.

In figs. 1 and 2, *a* are the walls of the cameras, *a'* is a tube fixed to the

camera and which carries the lens. *b b* are four plate-holders sliding in grooves in the ordinary manner, but placed at the four sides of the camera instead of at the back as is usual. *c* is a frame, the front of which revolves on the ring of balls, *d*, surrounding the tube, *a'*, and the back carries the shaft, *e*, which revolves in the ball bearing, *f*. *g* is a mirror fixed to the frame, *c*. *h* is a spring having one end fixed to the shaft, *e*,

and the other to the camera. *j* is a four-toothed ratchet or cam wheel fixed to the shaft, *e*, and *k* is a bolt engaging with it. *l* is a flexible ball placed between a lug, *a''*, on the camera and a lug, *k'*, on a lever, *k''*, operating the bolt, *k*. The ball, *l*, is connected by the tube, *m*, to a second flexible ball, *n*. By squeezing the latter the ball, *l*, is expanded, the bolt, *k*, is withdrawn and the frame, *c*, and mirror, *g*, are revolved through a quadrant by the spring, *h*, and are then again arrested by the bolt, *k*, engaging with the next tooth of the ratchet wheel, *j*. This forms a very

convenient arrangement for manipulating the mirror, but any other suitable device may be employed.

In fig. 3 the frame, *c*, is dispensed with, the mirror, *g*, being fixed to the tube, *a'*, which in this case is free to revolve in the ball bearing, *m*, and constitutes a hollow shaft carrying the mirror.

By this arrangement a smaller mirror is required. In this figure the means for rotating the mirror are not shown, they may be the same as in figs. 1 and 2.

#### THE USE OF SCREENS IN NEGATIVE AND POSITIVE WORK.

MR. R. R. BEARD has patented a process of this kind, which he thus describes in his specification:—

"I make a photographic negative or positive by employing before the sensitive photographic plate or film a ruled gridiron or other screen, which has (say) spaces one half the width of the bars or rulings of the screen, so that, if an exposure is made, I obtain a negative made up of lines with spaces double the width of the exposed portion—sixty or eighty bars to the inch is a suitable number. Now, if I move the screen so that the bars or rulings overlap the exposed portion and expose again, and so on with the third portion, in this way I obtain three negatives of different objects on one plate, or as many more or less, according to the width of bars or rulings as the screen affords.

"The screen can be a photograph, or anything so long as it serves the purpose to screen the sensitive plate or film.

"A positive produced from such a negative can be used in conjunction with a screen similar with that which the negative was taken for various purposes, such as, for instance, a magic-lantern slide. In this case I employ a frame in which is fitted two movable frames, one for the screen and one for positive or negative (if desired). I move one of these by a screw, and thus display the three pictures in succession.

"Or in window decoration or advertising, if the transparency, when mounted with the screen, be viewed at different angles, either of the photographs can be seen."

#### AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

At a meeting of the Executive Committee, held at No. 66, Russell-square, on Tuesday, November 21, 1899, Mr. G. Scamell (Hon. Treasurer) in the chair, it was decided to at once issue a letter to the various affiliated societies, asking for official information as to the dark room and other conveniences at the disposal of members of affiliated societies, delegates, &c., for inclusion in a small pocket volume intended to give particulars of everything appertaining to the affiliation. It is hoped that this volume may be an annual one, and that the first will be issued early in the new year, sufficient copies to provide one for every member of the affiliated societies being printed.

It was also decided to ascertain what societies would wish to avail themselves of an organized interchange of lecturers, and to ask for their opinion as to the possibility of extending the "grouping" scheme in different centres.

A suggestion was considered for the circulation of the affiliation lectures longer in advance than is now practicable, and for the supply of abstracts of the lectures, with formulae, &c., to be retained by the societies borrowing same. Steps will be taken to supply the lectures booked to societies ten days in advance, to allow the reader thereof time to become acquainted with the subject-matter before the meeting takes place.

To meet the expressed desire of several societies for the services of a travelling lecturer, the Committee directed that some preliminary steps be taken to ascertain the feasibility of such an arrangement, and upon this a formal pronouncement will be made as soon as possible.

Negotiations are in progress for a lecture upon "Photography in Natural Colours," which will treat of every process now being worked, and will be illustrated as far as possible.

It was announced that a lecture upon "Rejlander: his Life and Work," by Mr. A. H. Wall, illustrated by slides of many of his best pictures, will be ready for circulation before very long.

The Committee entertain the hope that they will be able to secure the services of an eminent authority for the preparation of a critical lecture upon modern photographic picture-making, as exemplified in the work of the exhibitions during the past few years. Every effort will be made to circulate with it prints or slides of the pictures referred to.

## Our Editorial Table.

#### NATURALISTIC PHOTOGRAPHY.

By P. H. EMERSON, B.A., M.B. (Cantab.), F.R.P.S.

Third Edition, revised, enlarged, and rewritten in parts. Price 5s.

London: Dawbarn & Ward, 6, Farringdon-avenue, E.C.

WHEN a fourth edition of Dr. Emerson's book is published we hope that the printing will be done in England, so that the author may have the opportunity of supervising the work as it passes through the press. In the present case the book suffers from the fact that it appears as a specimen of American typography, which has not had the advantage of the author's revision, and thus, here and there, we come across some examples of transatlantic spelling, and one or two minor errata, which disfigure the pages of the volume. One can sympathise with Dr. Emerson in the annoyance of having his book maltreated in this fashion; and we are sure that no reviewer of gentlemanly feeling, in the circumstances of this case, would treat such unimportant slips as pegs upon which to hang an adverse criticism.

It is eight or nine years since the last edition of *Naturalistic Photography* was published, and, no doubt, there are to-day large numbers of photographers who will make the acquaintance of the book for the first time in its third edition. Of the new readers who will turn over its pages it may safely be conjectured that a very large percentage will be ignorant of what Dr. Emerson has done for photography. Neither the man nor his work is sufficiently known to the general photographic public, and for this state of things the person most responsible is Dr. Emerson himself. In an age when any charlatan can catch the ears of the mob by persistent shouting, Dr. Emerson is content to lead the life of a silent country gentleman in Norfolk, and eschew vulgar self-advertisement. He does not go lecturing on pictorial photography on the smallest provocation, or reproduce his own pictures in a newspaper, or publish never-ending lengths of penny-a-lining diffidence upon that topic, with the most unblushing and wearisome reiteration year after year. In other words, Dr. Emerson disdains to force himself down the throats of the photographic public, and, if he thus misses notoriety, at least exchanges it for respect.

But Emerson's place in the history of the development of pictorial

photography in Great Britain—and, for that matter, the world—is assured. When the photo-faker and all his works have been swept into the dustbin of time, three personalities will stand forth with the greater clearness to the gaze of the student of the future. We mean those of D. O. Hill, Mrs. Julia Margaret Cameron, and P. H. Emerson. The first two in portraiture, and the last in landscape and figure work, have, in the phrase of the time, "got more out of" photography than anybody else in the interpretation of human character and the sentiment of nature. In these days of illustrated photographic periodicals, nobody interested can fail to acquaint himself with the Hill and Cameron broadly treated portraits to the extent which the half-tone process, despite its imperfections, allows, but it is a thousand pities that Dr. Emerson's work is so inaccessible. In some of his books, notably *Life and Landscape on the Norfolk Broads*, *Pictures from Life in Field and Fen*, *Idyls of the Norfolk Broads*, and, above all, the magnificent *Pictures of East Anglian Life*, as well as in several separate plates, amongst which the dainty *Gathering Water Lilies* was more imitated than almost any other photograph we know—in these books, produced with a painstaking carefulness and labour which stamp the author as a thorough genius, there are a great number of photogravure reproductions from his negatives (direct, untouched, unfaked negatives, let it be marked), which, in our deliberate opinion, form a collection of the most wonderful and faithful nature photographs that have ever been produced. Of their kind nothing to-day excels or even equals them, and we repeat that it is a thousand pities they are not accessible to all modern photographers. But there must be many who can recall individual pictures, and as we write we pause and think, What arresting charm and conviction there was in the always delightful *Poacher*!

*Naturalistic Photography* should be considered as merely a part of the fine and conscientious work which Dr. Emerson, still fortunately a young man, and with his best working years in front of him, has contributed to art and literature. It cannot be adequately appreciated without a knowledge of the man. To his unflinching thoroughness there is no limit. He is sincere in all that he undertakes. In a *Son of the Fens*, for example, he gives a minute study of a Norfolk peasant from youth to man's estate, derived from actual and close observation. His pictures of East Anglian life were, so to speak, sketched and finished on the spot, for the author lived and worked amongst the very people he was closely observing. So, again, in *On English Lagoons*, the record of a year's wherry cruise on the Broads, not a line found its way into that fascinating record of a natural history tour which was not the outcome of keen observation and accurate knowledge.

It is precisely these faculties which Dr. Emerson brought to bear in the study of pictorial photography, which he took up some fourteen or fifteen years ago, when he produced some of his best work. *Naturalistic Photography* was the literary result of that study, and the book was preceded by object-lessons in the shape of the photographs to which we have referred. Thus Dr. Emerson has always sought to teach by his examples as well as his precepts, and the ideal edition of his book, which we hope one day to see published, should be illustrated by reproductions of his own photographs.

"A naturalistic photograph must be

"(1) True in natural sentiment;

"(2) True in appearance to the point of illusion;

"(3) Decorative."

In these sentences we have the key to Dr. Emerson's teachings in the volume before us. It is divided into three books, and there are some appendices. "Impressionism in Pictorial and Glyptic Art," "Phenomena of Sight, and Art Principles Deduced therefrom," "Naturalistic Photography and Art," "Technique and Practice," "Pictorial Art," "Photography not Art," are some of the subjects exhaustively dealt with. Those portions of the book which trace the characteristics of each nation's art, as well as some of the chapters devoted to the camera, the dark room, and so forth, are possibly not vital or even essential to a comprehension of what Dr. Emerson has to say on pictorial photography and its study. The author's characteristic vigour of expression may occasionally surprise, but it can never offend, for his manly advocacy of the pictorial photograph, which is the outcome of sincerity, observation, and truth, cannot but win him the regard of all interested in the progress of "pure photography" as opposed to mere photo-faking.

Of *Naturalistic Photography* we have before expressed the opinion that it is one of the most notable books that have ever been produced in connexion with the subject, and the new edition before us finds us of the same opinion still; but thorough justice will never be done to the author until a fourth edition is published which substitutes for some of the not very necessary chapters on technique a number of reproductions from his photographs, so that Emerson's theory and practice may stand side by side for all to profit by.

In conclusion, it will be well to remind our readers that the author withdrew his second edition, because he was convinced by his own researches and those of his painter friend, that no photographs give reproductions of nature as the eyes see it, and because of the impossibility of strengthening or making selected tones by development as proved by the researches of Dr. Hurter and Mr. Driffield. That is the true reason of the withdrawal of the second edition in a nutshell, and the third edition views photography from this standpoint.

# TELE-PHOTOGRAPHY: AN ELEMENTARY TREATISE ON THE CONSTRUCTION AND APPLICATION OF THE TELE-PHOTOGRAPHIC LENS.

By THOMAS R. DALLMEYER, F.R.A.S. With 26 plates and 66 diagrams. 145 pp. and a Bibliography.

London: William Heinemann.

THESE are parts of Mr. Dallmeyer's new book which make an especial appeal to all portrait photographers. In the seventh chapter, when dealing with the practical applications of the tele-photographic lens, he dwells upon its uses in the avoidance of distortion in portraits, or, as he succinctly puts it, "aiming at too large an image with a lens which is too short in focal length to allow an adequate distance to intervene between sitter and lens for good perspective drawing." We have several plates in the book, made respectively from negatives obtained with portrait and rectilinear lenses and lenses with tele-photographic attachments, illustrating the difference between good and bad perspective, which we commend to the study of portrait photographers, especially those with short studios. For drawing attention to the advantages of tele-photography in obtaining portraiture in true perspective, Mr. Dallmeyer deserves general thanks, and, when those advantages are more widely known, we shall expect to see them availed of by many. The book is addressed to those who practise photography either for pictorial or scientific ends, and it aims, and we think successfully so, at arresting the understanding of those having only a slight acquaintance with the science of optics. To this end the author devotes his second chapter to a discussion of the formation of images by the pinhole camera and, most importantly, its perspective drawing; and this is done so lucidly and simply that the reader is easily prepared to follow Mr. Dallmeyer into those branches of his theme which deal with tele-photography in theory. Chapters III. and IV. are concerned with the subjects of the formation of images by positive and negative lenses, and Chapter V. with the formation of enlarged images—the very pith of the book. The use and effects of the diaphragm, practical applications, and working data next take the reader from theory to practice.

The illustrations are as fascinating as they are instructive. We see again the famous photograph of Mont Blanc, taken at a distance of forty-four miles; enlarged pictures of the human eye, obtained by tele-photography; eclipse photographs; distant Alpine views, by Dr. Spitta; reproductions of balloon tele-photographs, by Captain Mario Moris, of the Italian Government; bird work, by Mr. Lodge; architecture, by Mr. Cruickshank; and some of the author's long-distance marine view work—all illustrating the wonderful power of tele-photography in delineating on the sensitive plate images which, when made with the ordinary lens, are comparatively insignificant, if not unrecognisable. Even in its illustrations alone Mr. Dallmeyer's book makes a powerful appeal to the imagination, and shows more vividly than words can express the inestimable value of the tele-photo attachment in long-distance photography.

Notwithstanding that the book is an elementary one, it by no means leaves its subject unexhausted, and there is no doubt that it at once takes pride of place as the most important books on tele-photography yet published. In a characteristically graceful preface Mr. Dallmeyer reviews the efforts of other labourers in this sphere of work, and pays the compliment of recognition to Barlow, Porro, Traill Taylor, Miethe, Steinheil, Schroeder, and others who had preceded him with their publications and constructions. But the fact remains that it is Mr. Dallmeyer himself who deserves the chief credit for having given tele-photography, in theory and practice, the prominence it now enjoys, by the paper on the subject which he read at the Camera Club eight years ago.

The book is handsomely produced and illustrated, and should prove in the highest degree instructive to many classes of photographers, from military strategists down to humble portrait photographers, who may be desirous of availing themselves of the unique facility which tele-photography affords of obtaining greatly enlarged images with a short extension of camera. But it will come with surprise to most readers to be told that, besides Mr. Dallmeyer himself, only three other English writers have dealt with the practical applications of tele-photography—Mr. Lodge, Mr. Marriage, and Dr. Spitta.

Messrs. BURROUGHS, WELCH, & Co., of Snow Hill-buildings, E.C., send us a copy of *Welcome's Photographic Diary and Exposure Record, 1900*. It is a compact pocket-book such as the amateur photographer can always carry with him. The greater part is devoted to ruled pages for recording exposures, and to exposure tables, diary, and memoranda pages. The printed matter is mainly such as will be serviceable to every photographer whether a user of "tabloid" chemicals or not. The book may be obtained of any photographic chemist, dealer, or bookseller.

Owing to great pressure on our space we are obliged to hold over several notices, including one of a new plate by Messrs. Cadest and Neall—the "Royal."

## News and Notes.

AMONGST the list of contributions to the Mansion House Refugee Fund we notice that of Kodak (Limited), 105*l*.

PHOTOGRAPHIC CLUB.—Wednesday evening, December 6, 1899, at eight o'clock. Demonstration of "Gravura," by Paget Prize Company.

OBSERVATIONS OF THE BIELAIDES.—Successful observations of the Bielaides were made by the astronomers of the Vienna Observatory last week from Sonnwendstein Peak, in the Austrian Alps. Sixty-seven shooting stars, mostly from the constellation of Andromeda, were seen from the beginning of evening up to moonrise. Also a magnificent fireball was observed shining in the constellation. Twelve photographs were taken.

We are informed that a photographic Society has been started in South Norwood known as the South Norwood Amateur Photographic Society. The meetings of the Society are held at the South Norwood Polytechnic on the second and fourth Thursdays in the month. Up to the present, forty members have joined. The subscription is 5*s*. per annum. The President is Mr. W. F. Stanley, of "Cumberlow," South Norwood. Communications should be addressed to the Hon. Secretary, Mr. E. Pierce, 26, Balfour-road, South Norwood, S.E.

THE TWENTIETH-CENTURY INTERNATIONAL PHOTOGRAPHIC EXHIBITION.—The display of photographs, which formed no strong a feature of last year's Exhibition at Bingley Hall, Birmingham, is to be repeated in March next in connexion with the Engineering and General Trades Exhibition, under the management again of Mr. Walter D. Welford. We understand that there will be competitions for the photographers' assistant, and one or two other novelties. The prospectus is in preparation, and, when ready, may be obtained from 19, Southampton-buildings, Chancery-lane, London, W.C.

CONSIDERABLE interest was manifested in the Borough Polytechnic Society's first monthly lantern-slide competition on the 22nd instant, members turning up in strong force. A good entry was obtained, and competition was keen throughout. Slides were judged in sets of three, and the least successful in each round were gradually weeded out, until only three slides remained. The best one of these three proved to be by Mr. E. J. Hoar, and was entitled *South Aisle, Ely*, for which he obtained the maximum number of ten points. He was closely followed by Mr. W. H. Andrews with *At Eventide* (nine points), and Mr. L. E. Cotterell was placed third with *Daffodils* (eight points). All slides were then criticised by the judges (Messrs. Bannister and Rawkins) as they were again projected on the screen, and points awarded.

THE Southsea Amateur Photographic Society's Twelfth Annual Photographic Exhibition will be held at the Society's rooms, 5, Pembroke-road, Portsmouth, on Monday, Tuesday, and Wednesday, January 29, 30, and 31, 1900. The following are the open classes: G, Landscape, Seascapes, and River scenery; H, Figure Studies, including groups, portraits, animal studies, and still life; I, Hand-camera Work, set of six prints, the camera to have been held in the hand during exposure; J, Lantern Slides, set of six; K, Beginners' Class, for those who have commenced photography since January 1, 1898; L, Not for Competition, exhibits invited. All exhibits must be delivered not later than Wednesday, January 24, 1900, to the Hon. Secretary, Mr. F. J. Mortimer, Southsea Amateur Photographic Society, 5, Pembroke-road, Portsmouth.

COLOURING BROMIDE PRINTS.—For oil colours, a hot solution of three per cent. of good white gelatine is spread upon the surface of the print by means of a wide and fine sable brush. After drying, according to M. Henry, the layer thus formed will take oil colours readily, and one may proceed to colour the print as desired. For water colours, the best results are obtained by the use of a solution of 120 grammes of shellac in 240 c.c. of alcohol. When completely dissolved, the solution is allowed to stand for twenty-four hours, and is diluted by taking 120 c.c. of the former and 120 c.c. of alcohol. This is to be filtered before using. The solution is applied to the surface of the bromide print by means of an atomiser until it appears to be slightly wet. When the print is well dried, which takes from ten to fifteen minutes, water colours may be applied as desired. If in certain parts the print does not take the colour sufficiently, the process of applying the solution is repeated in these places. The fixative varnish used for charcoal drawings, &c., may be used instead of the solution of shellac. The use of pastel is especially in favour for retouching or colouring bromide prints, but it is necessary that the paper should have sufficient grain, in order that the pastel may be readily applied. M. Henry has found that this grain may be obtained by the use of powdered pumice-stone in the following manner: A tuft of cotton is thoroughly impregnated with the powder, and, after having applied to the surface of the print a layer of the shellac solution above mentioned, the powder is applied by tapping lightly with the wad of cotton. The print should thus be covered with the powder before the solution is dry; in this way the powder attaches itself, and is fixed during the drying of the solution, leaving below a clear image. If necessary, the operation may be repeated until the desired grain is produced.

## Patent News.

THE following applications for Patents were made between November 13 and 18, 1899:—

RECORDING OSCILLATING LIGHT RAYS.—No. 22,613. "Improved Apparatus for Photographically Recording Oscillating Rays of Light." Complete specification. A. POLLAK, J. VIRAG, G. EGGER, and F. SILBERSTEIN.

DEVELOPING APPARATUS.—No. 22,614. "An Improved Automatic Developing Apparatus for Photographic Exposures." Complete specification. A. POLLAK, J. VIRAG, G. EGGER, and F. SILBERSTEIN.

CAMERAS.—No. 22,676. "Improvements in Photographic Cameras." Complete specification. D. H. HOUSTON.

ARTIFICIAL LIGHT.—No. 22,747. "Improvements in Apparatus for Producing Light for Photographic Purposes." W. H. SMITH and W. WILLIS.

KINEMATOGRAPHS.—No. 22,954. "Improvements in Kinematographs." L. E. GRANTICHTAEDTEN.

CAMERAS.—No. 23,039. "Improvements in or relating to Photographic Apparatus applicable to a Camera." Complete specification. A. LÉON and W. H. ENGLAND.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

December.	Name of Society.	Subject.
4.....	Bradford Phot. Society .....	{ East Anglia and Adjacent Counties. Godfrey Bingley.
4.....	Camera Club .....	{ Travels in Ashanti and Neighbouring Countries. Dr. R. Austin Freeman.
4.....	Cripplegate Photo. Society .....	Gracina. A. C. Baldwin.
4.....	Darwen .....	Prize Slides.
4.....	Glasgow and West of Scotland .....	Demonstration: <i>Velox</i> Paper. Mr. Belton.
4.....	Kingston-on-Thames .....	{ Exhibition of Slides lent by the Royal Photographic Society.
4.....	South London .....	{ A Brief History of British Architecture. W. H. Dawson.
4.....	Stafford Photo. Society .....	Portraiture. M. Averill.
5.....	Bristol and West of England .....	Elementary Technical Instruction Meeting: The Negative. Henry Ormerod.
5.....	Gospel Oak .....	Demonstration: <i>Gravura</i> Paper. Paget Prize Plate Company.
5.....	Hackney .....	{ A Practical Lesson in Outdoor Photo- graphy. A. Horsley Hinton.
5.....	Redhill and District .....	Demonstration: <i>Kachin</i> Developer, <i>Velox</i> . Messrs. J. J. Griffin & Son.
5.....	Royal Photographic Society [ .....	Lincoln Cathedral. Frederick H. Evans.
6.....	Borough Polytechnic .....	Here and There with a Hand Camera. R. Child Bayley, F.R.P.S.
6.....	Croydon Camera Club .....	Secco Film.
6.....	Photographic Club .....	Demonstration: <i>Gravura</i> . Paget Prize Company.
6.....	Southsea .....	British Architecture. A. Fisher, A.S.A.
6.....	West Surrey .....	Demonstration: <i>Secco</i> Films.
7.....	Ashton-under-Lyne .....	Demonstration: <i>Dekko</i> and other East- man Papers. Robert Hobbs.
7.....	Camera Club .....	Photographic Surveying. Bridges Lee, M.A.
7.....	Ile of Thanet .....	Demonstration: <i>Gravura</i> . A.C. Baldwin.
7.....	Liverpool Amateur .....	Demonstration: The Evolution of a Snap-shot. F. Anyon.
7.....	London and Provincial .....	Elementary Composition and Perspective. W. R. Stretton.
7.....	Oldham .....	Lantern-slide Making. W. A. Nash.
7.....	Tunbridge Wells .....	Technical Control for Pictorial Results. W. Thomas.
7-9.....	Woodford .....	Members' Exhibition.
8.....	Borough Polytechnic .....	Practical Evening: Bromide Enlarging by Artificial Light.
8.....	Bristol and West of England .....	Demonstration: Films of the Secco Com- pany. Secco Film Company.
8.....	West London .....	Demonstration: Enlarging. L. Selby.
8.....	Whitby .....	Lecture: A Practical Lesson in Outdoor Photography.

### ROYAL PHOTOGRAPHIC SOCIETY.

NOVEMBER 28,—Technical Meeting,—The Rev. F. C. Lambert in the chair.

#### MR. WHEELER'S "METZOGRAH" SCREENS.

The ASSISTANT SECRETARY passed round two examples of the use of Mr. James Wheeler's "Metzograph" screens for process work, one of them a pull from the first block made with one of the screens, and the other a specimen of a print which will appear in the next issue of the *Photographische Correspondenz*. These screens are intended to impart an even and ungeometrical grain of any desired size, and are applicable to ordinary studio work or to process work. In the first case, they are placed with the grained surface separated from the negative by the thickness of an indiarubber band, and in process work the screen may be placed at the same distance from the plate in the camera, the exposure being the same as without the screen. A modification of the method of manufacture is applied for producing a kind of very fine ground glass for focussing screens, and also for reticulating ruby glass for diffusing the light of a dark-room lantern.

MR. SNOWDEN WARD said that, although Mr. Wheeler's screens had not at present been adopted by process workers in this country, they were used by several Continental firms with such success that they had recently sent orders for sizes up to forty by thirty inches. An essential advantage which they possessed lay in the fact that no opaque material was employed for filling up the inter-spaces, so that the light was not obstructed, but only diverted from its path, the exposure being thus reduced to about one-third of that required with screens of the ordinary character.

#### THREE-COLOUR LANTERN SLIDES.

MR. E. SANGER SHEPHERD read a paper on "Practical Three-colour Lantern Slide-making," and showed a number of slides produced by a method which he has recently brought to a high degree of perfection, the results being capable of projection by an ordinary single lantern. Having alluded to the work of Clerk-Maxwell in 1861, of Du Hauron up to 1875, and of F. E. Ives, he said that the present process was based on the fact that all the colours of

nature may be counterfeited, sufficiently nearly to deceive the human eye, by mixtures of particular red, green, and violet colours. The first practical step towards making colour photographs was attained when Dr. Eder and Captain Abney started the sensitising of plates for colour; and Captain Abney's new measurements of colour curves, when finally revised and published, would greatly simplify the work of colour measurement and materially help the attainment of really accurate results. In Mr. Ives's Kromskop process there was a mixture of coloured lights, but the method which Mr. Shepherd was describing was one in which three coloured films were superposed, the absorption of one print being thus added to the absorption of another; and for that reason the colours used by Mr. Ives for the three positive transparencies were not suitable in this case, in which the colours were respectively minus green, minus blue, and minus red. The screens for taking the three negatives, which are now on the market, could not have been made commercially without the aid of the colour sensitometer invented by Captain Abney; and Mr. Shepherd had devised a modification of a camera, designed in 1868 or 1869 by Du Hauron, with which the three negative images could be obtained of identical size and with one exposure. The positive transparency for the blue print was best made as an ordinary black lantern slide, afterwards toned blue with a solution sold with the apparatus for the process, and finally used as a cover glass. The pink and yellow prints were made on very thin and transparent celluloid films coated with bichromated gelatine containing a small quantity of bromide of silver, the latter rendering the image visible. After printing, the images were developed with warm water, and the silver removed by a weak hypo solution, leaving a picture in clear gelatine. The print from the negative through the red screen was then to be stained with a greenish-blue solution, that from the negative through the green screen in a pink solution, and that from the negative through the blue screen in a yellow solution. The pink and yellow images were next placed in accurate register upon the blue image on a lantern plate, and the whole bound together in the usual way. If, however, the slide were to be projected with a long-focus lens, this method of mounting would entail the scattering of a great deal of light and a consequent loss of brilliancy, and it was better in this case to cement the films together with Canada balsam. In the course of the evening slides mounted in both these ways were shown side by side on the screen, that sealed with Canada balsam having a very great advantage over the other.

In the course of the brief discussion which followed the reading of the paper,

MR. CHAPMAN JONES asked whether it was possible to over-stain the films by allowing them to remain for too long a time in the solutions, or were they correct when they had absorbed to their maximum absorptive power?

MR. SANGER SHEPHERD said the staining solutions were mixtures of different dyes, and were of such a character that they could be washed out of the films if it was desired to do so. If the three images were correctly stained, the deep shadows of the picture would be of a neutral tint, and, if this was not the case in a particular slide, the over-stained film could be placed in water for a few minutes and the depth of colour would be reduced.

MR. BOLAS thought the sealing of the films with Canada balsam was a distinct advance upon former methods; but

MR. SANGER SHEPHERD said it was introduced by Du Hauron.

The CHAIRMAN emphasised the importance of the investigations carried out by Clerk-Maxwell at a time when his name was little known outside of Cambridge University, and which would have been regarded then by many as very dry and unproductive mathematics. He was one of the men of whom to-day England was proud, and whose brilliant genius would be recognised even to a greater extent by those who would follow us.

#### COMING EVENTS.

December 5, Lantern Evening, "Lincoln Cathedral," by Mr. Frederick H. Evans. December 12, Ordinary Meeting, "Notes on the Use of Mr. Dallmeyer's Focometer," and also "The Origination of Printing Types by Photographic Methods," both by Mr. T. Bolas. December 19, Photo-mechanical Meeting, "Negatives for Three-colour Work," by Captain W. de W. Abney, C.B., F.R.S.

#### PHOTOGRAPHIC CLUB.

NOVEMBER 22,—Mr. E. A. Newell in the chair.

MR. F. H. CARTER showed prints toned in the ordinary sulphocyanide bath, and in the combined bath for comparative purposes. The results were certainly not in commendation of the combined processes of toning and fixing.

MR. JOHN H. AVERY demonstrated the method of working Secco film in his ordinary business, in which it had largely superseded glass plates.

Secco, it had been pointed out, was thirty years old at least, but Mr. Avery thought that he might say, at any rate, that at the present time it was a new departure. The method of preparing the film was briefly that a piece of paper was coated with a substratum, then with a layer of Secco film, and on that with the sensitive emulsion. The second film is simply Secco film coated on paper, and its use is as an auxiliary or protective film. The film is exposed in the usual way in the dark slide or roll-holder, a piece of card in the former case being used to keep the film flat. Card was sufficient for the purpose up to whole-plate, or even 12 x 10, but for bigger sizes a carrier was required. The speed of the emulsion was about eighty H. & D. It was up to the present of German manufacture, but the English Company would soon be turning out home-made supplies. After exposure, the film is placed in two per cent. of glycerine and water for a minute, and in this only does its preliminary treatment differ from that of plates. The solution keeps the film from curling. Pyro ammonia, or anything, in fact, could be used for development. After fixing and washing, a piece of the auxiliary film is soaked in the glycerine solution for a time, then the negative is drawn up in contact with it, lightly squeezed, and allowed to dry in between blotting-paper. The negative is now enclosed between two sheets of paper. It is best to trim away all roughness of edge before stripping, an operation which is simplicity itself. One then has a negative film which is protected by two layers of Secco film, one on each side,

of an entire thickness of one five-hundredth of an inch. It is non-inflammable. It can be crushed up into a ball in the hand, and ironed out flat again. Both sides may be retouched without medium. The negative may be printed from either side. It can be made in any length. There is no possibility of halation, and a print from a plate and a film were shown to bear this out. The subject was identical, but the glass negative was very poor on account of halation effects. As regards intensification or reduction, this should be done before the auxiliary film is applied. If the necessity for intensification or reduction is not perceived until after the stripping, the operations previously described may be reversed. The negative is soaked in glycerine solution. Pieces of auxiliary film are squeezed to it, and then separated, so that the emulsion film is exposed again. The intensification may then be effected. Mr. Avery showed the operations required, and passed round many negatives and positive transparencies, and enlargements and prints were placed around the room.

**Croydon Camera Club.**—Between twenty and thirty members attended on Wednesday, the 22nd ult., to hear a talk by Mr. A. C. BALDWIN upon

THE GRAVURA PRINTING PROCESS AS APPLIED TO PAPER, OPAL, AND GLASS.

Although in the main manipulations are akin to what are gone through with similar types of paper, some variations were noticed. Gravura, like Velox, may be handled in the ordinary light of a room lit by gas or electricity, yet, strange as it may seem, a mere half-inch of magnesium ribbon burnt at a distance of thirty inches will strike right through the negative and impress the paper, so that, on taking it from the printing frame and placing it into a reducing solution, a full black image immediately appears. A print may thus be exposed and developed inside half a minute. The paper, opal, or lantern plate will not only print black, but, without any further treatment than development, will yield brown or red tones. To obtain these, instead of half an inch, if three inches of magnesium are burned, brown tones ensue, while, if four inches be used, the tone is that of red crayon. In each of these two cases the developer is somewhat diluted, and carbonate of ammonia added to it. With brown tones the development takes a normal time—a minute or more—so that it may be watched and controlled. It is preferable, if in doubt, to over-develop, the print being easily reduced after fixing by employing a diluted solution of Farmer's reducer (ferricyanide of potassium and hypo).

**Baling Photographic Society.**—November 20.—Mr. J. T. SANDELL, of the Sandell Film and Plate Company (Limited), attended for the purpose of giving a demonstration with

#### THE NEW PERFECT FILM

which the Company are about to place in the hands of photographers. Mr. Sandell prefaced his demonstration with a display of lantern slides and prints illustrative of the capabilities of the well-known multiple-coated plates which bear his name. The slides, which numbered about 100, were reductions from negatives of Mr. Sandell's own taking. In definition, technique, and *vraisemblance*, the slides could hardly be surpassed. In commencing his demonstration, Mr. Sandell explained that the Perfect film corresponds to the Sandell double-film plate, consisting of a slow and a rapid emulsion superimposed. The new film is composed solely of the two emulsions without any "support," and development consequently proceeds from both sides, with the result that the time for development and subsequent fixing is materially shortened. Mr. Sandell proceeded to develop four films simultaneously which had been exposed for 1, 5, 60, and 300 seconds respectively, and the result proved the very considerable latitude which the new films allow in exposure.

**Richmond Camera Club.**—November 13.—Lecture by Mr. H. T. MALBY, F.R.P.S., on

#### THE PHOTOGRAPHING OF FLOWERS,

illustrated by some fine lantern slides, was read. Mr. MALBY advocated the use of isochromatic plates, aided in some cases by coloured screens, but he warned his hearers against the indiscriminate use of the latter, and showed, by means of slides, that the truest results were often obtained by the use of the plate without the screen, pictures so taken being compared with the same subjects taken with a screen, in order to show the over-correction of the colours produced thereby.

NOVEMBER 20.—A paper, by Mr. A. HORSLEY HINTON, on

#### PLATES AND PAPERS FOR PICTORIAL PHOTOGRAPHY,

was read. Mr. HORSLEY HINTON strongly advocated the use of isochromatic plates, and, where possible, of a slow plate. He preferred platinum to any other printing process, and described his method of printing by means of a board covered with cloth, on which the paper, with the negative above it, was laid, the position of the negative being fixed by six stout pins, two on each of three sides of the negative, passed through the paper and cloth into the board. This allowed the negative to be removed bodily, and replaced in exactly the same position as before, and the whole of the print could consequently be seen at once. He also described his method of printing in a sky or figures from another negative, and of controlling the action of the light by means of tracing paper on the back of the negative, blackened with charcoal where necessary.

**Liverpool Amateur Photographic Association.**—November 16.—A lecture was given by Mrs. E. MAIN. Mr. Paul Lange presided, and there was a large attendance. The lecture was a demonstration in photography, as well as an interesting chat about a summer tour among the mountains and fjords of Norway. Mrs. Main has climbed precipitous mountains, and tramped almost interminable glaciers, where nothing was visible but eternal snow, and bare, bleak, craggy mountains, whose serrated peaks spread around her on every side with appalling ruggedness and wild grandeur. All these things she discoursed pleasantly upon for a couple of hours, illuminating her story with many humorous touches. About a hundred pictures were shown, all of which, as well as the slides, were done by herself. Mrs. Main is an enthusiastic mountaineer, and a very competent photographer. Some of the cloud effects obtained by her are wonderful, and her rendering of snow scenes was no less magnificent. She was rewarded with a cordial vote of thanks.

NOVEMBER 25.—Mr. HARRY WADE, of Manchester, read a paper on  
INTENSIFICATION AND REDUCTION.

Mr. Wade told his hearers that photographers were too fond of using one formula for all kinds of intensification and one kind of formula for all kinds of reduction, and gave several formulae for each. These varied for intensification from the well-known mercury and ammonia to the lesser-known methods of redevelopment by means of cyanide of silver, and for reduction from the well-known Farmer reducer to the newer methods by means of persulphate of ammonia and permanganate of potash. Mr. Wade, whose remarks were listened to with great attention, passed round specimens of negatives intensified or reduced by each of the methods he advocated, and at the conclusion gave a practical demonstration of his various formulae.

**Rotherham Photographic Society.**—November 21.—Mr. T. G. HIBBERT (Hon. Treasurer of the Sheffield Photographic Society) dealt with the subject of

#### GOLD TONING OF P.O.P.

Mr. Hibbert's method is to make use of old sulphocyanide and gold baths strengthened as required. The addition of two or three drops of gold solution affords clue by colour as to which of the two chemicals is requisite.

**Southsea Amateur Photographic Society.**—November 22.—A demonstration of Eastman's Dekko paper was given before the members of this Society by Mr. PERCY HUME. After the demonstration, the HON. SECRETARY stated that he had made arrangements with Mr. H. Snowden Ward to give a lecture on "Dickens Land." He pointed out, however, that such a lecture should prove extremely popular if given in a large public hall in Portsmouth, which was Dickens's birthplace, and was closely associated with the great author. He asked for the co-operation of the entire Society in forming a committee to guarantee the expenses, and proposed that the entire profits of the undertaking given under the auspices of the Southsea Amateur Photographic Society should be handed over to the South African War Fund for the benefit of the widows and orphans of those killed in active service. This met with the entire approval of the members present, and over six guineas were collected at once towards the guarantee fund. Mr. MORTIMER then stated that he had entered into communication with the Mayor of Portsmouth for the hire of the Town Hall for December 12 next for the purposes of the lecture, and drew attention to the fact that the hall was one of the largest in the south of England, seating over 2000 people, and that, to make the affair a success, every one would have to work hard, as the time was short. On Saturday afternoon the HON. SECRETARY gave a practical demonstration of daylight enlarging with the Society's enlarging apparatus, and afterwards gave further particulars and details of the Dickens lecture, and distributed circulars and tickets to the members for them to sell, and everything seems to promise success for the venture.

**Carbon Portfolio Club.**—The Annual Meeting was held on November 23, when the following gentlemen were elected Councillors for the ensuing session:—*President:* Dr. H. Scott Lauder, R.N.—*Council:* Messrs. W. J. Croall, C.A., J. Warrack, jun., Douglas Croall, and T. Knoblanck.—*Secretary and Treasurer:* Mr. Stewart Wallace, W.S. On the motion of Mr. Eddington, a cordial vote of thanks was accorded Mr. James Hay, the retiring President, also to Dr. H. Scott Lauder for his most efficient services as Secretary during the past two years. The financial statement showed a satisfactory balance in hand. At present there are no vacancies, the membership of the Club being at full strength. A proposal to increase the limit of membership was not favourably received. In the course of the evening Mr. Douglas Croall presented a handsome leather portfolio to the Club, so that in future prints varying in size might be passed round. Several members spoke of the valuable criticism received and of the experience gained through being connected with the Carbon Portfolio Club. It was also felt desirable that members should investigate any new and at the same time permanent printing process.

#### FORTHCOMING EXHIBITIONS.

1899.

December 1-18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.

" 7-9 ..... Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.

" 11-Jan.1900 Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.

" 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.

1900.

January 29-31..... Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.

April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### PRINT-WASHERS.

To the Editors.

GENTLEMEN,—I note a question, by one of your correspondents in your JOURNAL of November 3, as to a good print-washer for professional use. May I take this opportunity of recommending a washer which I have used for about twelve months, and which I have found to give great satisfaction, namely, Marion's sectional print-washer? I believe most photographers wash for two hours, but I consider one hour to be ample with this particular washing apparatus.—I am, yours, &c.,

A. E. STANLEY.

10, Ewart-road, Bedminster, Bristol, November 20, 1899.

### SPOTS ON MATT-SURFACE PRINTS.

To the Editors.

GENTLEMEN,—I am much interested in the letter of last week's JOURNAL re spots on matt-surface prints. I am troubled in the same way exactly. I have used the same brand of paper for nearly three years, and it is only quite recently these markings have shown themselves. I can honestly say, with the writer of the letter in your JOURNAL, that I have taken every possible caution that I can think of, and still they appear, and only after mounting a few days. Fortunately, I have detected before sending prints out, but there still remains the possibility of spots appearing after prints have been sent home to clients. If any of your readers have had the same trouble, and overcome it, I for one shall be most grateful for any information that they can give. I have been a regular subscriber to your paper for nearly twelve years, and value very much any hints and sound advice that you so often give us. Thanking you in anticipation,—I am, yours, &c.,

PROFESSIONAL.

### THE HACKNEY EXHIBITION AND THE HAND CAMERA.

To the Editors.

GENTLEMEN,—I know that I am getting an old man, and so I feel grateful to your Hackney Exhibition reporter for bringing me back to at least twelve years ago. I feel quite young again, and fresh enough to go for him. Time was when I championed the hand camera against all and sundry, but these last few years have seen such a growth of hand-camera work that my mission was absolutely smothered. It is refreshing to hear the bugle-call of war once more, and, as an old horse, I cannot resist the call to arms. Moreover, I will promise you, gentlemen, that there shall be no misuse of the white flag. Your reporter's exclusive report is to the effect that a certain picture of mine in the hand-camera class, which gained an award, might just as well have been taken in a stand camera, because it shows no evidence of motion. He therefore takes it, I presume, that the hand camera should only be used to do something that the stand camera will not do. Well, now, I put it quite the other way. If the picture in question had been a stand-camera result, I should have written, had I been your reporter, that it might just as well have been taken in a hand camera, so as to prevent the necessity of lugging about a tripod and focussing cloth, the focussing, and the crowd of passers-by, who throng round the apparatus. Why, then, take a stand camera when a hand camera will do the work?

The question as to "time" exposure is too much for me, as it is put in such a loose fashion, for all exposures can be timed.

It is rather curious that, just at the end of my exhibiting career, in about the last competition I shall take part in, I gain an award, and your reporter tackles the hand camera. This is a curious and incentive combination, compelling me to occupy space in your columns. But, as it may be thought that there is something behind the criticism (people have a knack of surmising a thing of this sort), I must add that the picture in question was strictly in accordance with the rule governing the class, viz., "work done with a camera held in the hand, without other support than that of the body." It was taken from the ordinary street pavement in a Tella hand camera lens at full aperture (approximately f-6), and longest automatic exposure (approximately one second). There were three gentlemen with me at the time: Mr. Rogers, Hon. Secretary of the Croydon Camera Club; Mr. Newson, Hon. Secretary of the Fakenham Camera Club; and Mr. William F. Slater, of Lee, S.E.

As to the advisability of holding a hand-camera class at all, that is a matter for the Hackney Photographic Society, which is well able to take its own part: but I might add that objections to such a division, and to hand-camera work generally, usually spring from men who do not use hand cameras, and who therefore are not capable judges.—I am, yours, &c.,

WALTER D. WELFORD.

19, Southampton-buildings, Chancery-lane, W.C.

### ORTOL.

To the Editors.

HELLO, COLONEL.—I observe from the photographic papers of the world that a straight boom is on with the new developer, ortol. Being a Chicago citizen, and an amateur photographer of no mean repute, it struck me that your friends across the Herring Pond might reckon to note the experiences of a brother in the cult.

Well, here goes curtly, as I have no desire to take up too much of yours as well as my own time.

I selected one of the warmest days of our Michigan summer for my experiment with ortol. Outside, even under shade, the heat made one frigid. I started right away in my dark-room, and developed, perhaps, the best of a dozen exposed plates, and by the time I was half way through, the heat, even in my shirt sleeves, made me think, and don't you forget it. That Chicago sun was blazing on the roof of my dark-room in such a pertinacious manner that the water in the washing trough was hot enough for sepiá plat, and, Siree; it was under circumstances such as these that ortol stood the test. With this more than warm water streaming on the developed plates, one would have under almost any circumstances reckoned on bad frilling, but with ortol, no, Sir; after final washing there was not the slightest trace of it, and for this reason, if even this alone, I recommend ortol. And now, Colonel, I must quit, but should you ever cross to the U.S. be sure you come to Chicago, and I will show you round, and if you don't put in a good time it will be your own fault, and don't you forget it. My address is 17th-street, Section 46. Should you have trouble in finding, mention my name to the nearest constable.

And so farewell, yours, Senator JONATHAN WIDE-AWAKE.

Sports Club, Exchange-square, Chicago.

### THE ECLIPSE PHOTOGRAPH AT THE R.P.S. EXHIBITION.

To the Editors.

GENTLEMEN,—In your issue of the 13th ult. there appears, under the above heading, a letter from Lieut.-General Tennant, which please permit me, being the author of the photograph in question, to reply to.

General Tennant disputes the accuracy of the subject, with evident assurance on his own part, when he says "How the photograph was made I do not attempt to say, but I am quite certain it does not represent any phase of a solar eclipse, either at Quetta or elsewhere." This is tantamount to saying that the disc, as seen in the picture, is a "faked" arrangement, and literally accuses the "Royal" of accepting a photograph with no relation to the title applied to it. I will tell him exactly how the photograph was made:—

The camera employed was an ordinary (not solar) 12×10 one; the lens a Dallmeyer's 12×10 rapid rectilinear (not wide-angle), using the smallest stop, and without placing any coloured screen in front of the lens to soften or otherwise reduce the intensity of the light, there being great banks of clouds moving about, which, of course, I did not wish to lose. The lens was uncapped in the usual way, by hand, as quickly as it could be done; the plate was one of ordinary kind (not isochromatic) and sensitiveness, and the development slowly effected with pyro and ammonia. We are told by the General that the result obtained is reverse to what should be. I have in my possession several pictures of the eclipse, taken on the same day at Quetta by amateurs, and, although the results are indifferent, nevertheless the light encircling the black disc has the same appearance. This may also seem strange.

Should General Tennant still doubt the accuracy of the photograph, I am prepared to show him, or any one deputed by him to call on me, the original negative, which is in every detail an exact facsimile of the enlarged copy on view at the Exhibition.

Perhaps a more careful scrutiny of the picture (photographically) will convince the General of its technical correctness.—I am, yours, &c.

Quetta, Baluchistan, Nov. 6, 1899.

F. BREMNER.

To the Editors.

GENTLEMEN,—I have read in your JOURNAL of October 13, 1899, a letter from Lieut.-General Tennant on the subject of Mr. Bremner's photograph of the Solar Eclipse as seen in Quetta last year. This picture appeared in one of the London illustrated papers in the early part of last year, and, being greatly struck with it, I asked Mr. Bremner, in April 1898, to show me the negative. I know nothing about eclipses, but I have some years' experience of photography, and I can assure your readers that this negative had not been retouched or "faked" in any way whatsoever.

I have since been shown some amateur productions of the same subject which are in Mr. Bremner's possession, and the effect is precisely similar.

In justice to Mr. Bremner, I trust you will publish this letter, which has not been written at either his suggestion or invitation.—I am, yours, &c.

J. F. FORBES, Capt. 1st Wiltshire Regt.

Quetta, British Baluchistan, Nov. 4, 1899.

## LEAD PLASTER.

To the Editors.

GENTLEMEN,—In your Correspondence pages this week I see that "Varna" has mistaken Mr. Bolas's meaning in the term "lead plaster." Technically, I believe, all the combinations of metallic oxides (other than the usual alkalis) with oleic acid, are called "plasters." Lead plaster is one used in medicine. Watts states that it is flexible and tenacious in summer, but brittle in winter. If spread on a surface and warmed, no doubt films would adhere to it easily.—I am, yours, &c. J. F. T.

## SPOTS ON PLATINOTYPE PRINTS.

To the Editors.

GENTLEMEN,—Most probably the spots on platinotype prints that Mr. C. H. Ellis complains of, in your last week's issue, are caused by particles of soot settling on the negatives when printing, thereby keeping the light from acting on the paper directly beneath these particles.

Having had experience in printing in several large towns, I have found that at this time of the year soot is most troublesome, and will settle on printing frames placed outdoors, especially on a roof, and, unless it is blown off occasionally, will leave its traces in the form of a white spot on the print.—I am, yours, &c. M. E. MITCHELL.

Tonbridge, Kent, Nov. 27, 1899.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

## PHOTOGRAPHS REGISTERED:—

J. Rayne, Glendale Studio, Maldon, Essex.—Photograph of Miss E. H. Smee.

A. F. Clouston, Victoria-street, Stromness, Orkney.—Photograph of Stromness in fishing time.

E. H. Roberts, 30, High-street, Marlborough, Wilts.—Photograph of the Marlborough town beadle and choir.

INQUIRER.—Address the Platinotype Company, Bloomsbury-street, London.

E. H. ROBERTS.—We believe the maker named is dead; at any rate, he is not now in the business.

A. B. C.—1. We do not know either the lamp or the address of its makers. 2. Messrs. Thorne &amp; Hoddle's address is Tothill-street, Westminster.

MR. L. W. ELLINGTON (of Broadwell, near Rugby) desires to communicate with Mr. W. A. Gain, who wrote us last week on the preservation of potatoes.

PRINTS FOR PROCESS WORK.—ERIMUS asks: "To get the best results, should prints be used for process work be burnished or unburnished?"—Of very little moment so long as the surface is smooth and even."

ADDRESS OF A SCULPTOR WANTED.—W. D. asks for the address of a sculptor who undertakes to produce carved busts from photographs.—In reply: We are sorry we cannot give the information, which, however, some reader may supply.

THREE-COLOUR WORK.—H. ERNST says: "I wish to try three-colour photography. Would you be kind enough to give me your valuable advice with regard to the three negatives? When using the yellow screen, is the negative produced for yellow colour and the same with the red and violet screen negatives?"—In reply: Let our correspondent consult a paper in this JOURNAL for September 15 on the "Photography of Colour," and he will find an admirable résumé of three-colour theory and practice.

\* COPYING OLD POSITIVES.—G. BRIMMELL says: "I have received from a customer some old glass positives to copy, but the images are so dark all over that it is useless to attempt to copy them in their present state; can you tell me how and with what to bleach the image white again? I have tried them with the following formula: Terchloride of mercury, 1; bromide of potassium, 1; water, 50; but with no effect whatever."—Probably the pictures are varnished, and for that reason the solution has had no effect, and possibly so much the better for the pictures, for it is a very risky thing to tamper with old glass positives. Probably, if the black varnish at the back were removed, the pictures could be used as negatives and copies made in that way. Any how, make no further attempts to bleach them.

STAMP PORTRAITS.—LIVERPOOL. Cameras, and all the necessary appliances for taking these portraits, are supplied by Fallowfields, and, indeed, by most of the large houses.

PHOTO-RELIEFS.—M. O'CONNOR writes: "I want to make some electrotype medallions from plaster casts taken from gelatine reliefs. Can you tell me the best battery to use for the electrotyping? I am told that the Daniel is the best."—The Daniel battery is very good for the purpose, but we should prefer the Smee's. The latter is the one that is most in use by professional electrotypers who do not use the dynamo.

MATT VARNISH.—W. RESKER sends us a transparency backed with matt varnish, prepared according to the formula given in the ALMANAC, and complains that the grain is too coarse, and asks if it is possible to produce a finer one. Yes, it is, by simply adding less benzole. The larger the proportion of benzole used the coarser will be the grain, and the smaller the quantity the finer it will be.

LITHOGRAPHIC TRANSFERS.—J. R. FOX. If the ink, supposing it to be of the proper kind, will not wash off the paper when treated as you have done, it is clear that the paper is at fault. Either it has been much over-printed, or the gelatine has become insoluble, or non-absorbent of water before printing, possibly through too long keeping. The formula is right, and the gelatine used is of the right kind. Try again, and dry the paper quickly, and use it shortly after sensitising.

CARBON PRINTING; ROUGH PAPER.—CARBONENSIS asks: "Where can I obtain some rough Cresswick drawing-paper, prepared as single transfer paper, for carbon printing? I have inquired of several dealers up north, and they tell me that they have never heard of such a thing."—Probably the Autotype Company, or Messrs. Elliott & Son, will supply it. If they cannot, we do not know where you can get it, unless you prepare it for yourself.

STUDIO BUILDING.—INQUIRER says: "Will you kindly advise me as to best position and size of lights for studio 10x18 feet? Is it better to have both sides of roof at the same angle or not? Studio will stand east and west."—As the studio will be so small, we should say, Have both sides of the roof at the same angle. Have, say, four feet at either end opaque, and the rest glass. The south side, for easy working, need not be glazed, as both ends could be used as the background end according to the light.

CLEARING AN ORTOL-DEVELOPED PLATE.—REV. J. CARTER BROWNE says: "Having developed a Marion's plate with ortol, I put it straight into the hypo; when cleared, noticing a slight veil, I treated it with clearing solution (citric acid and alum), and placed in water to soak. In about an hour I found nearly all detail gone, and scarcely equal to a positive remaining. What caused this?"—We are sorry we cannot say the actual cause. Possibly the clearing solution was very strong, or the plate was left in it too long; or there may have been some disturbing cause beforehand, for ortol-developed negatives should not be veiled. Not necessary to print the address, thanks.

STUDIO BUILDING.—STUDIO says: "Thanks for answer in JOURNAL re studio building, but, as the sketch sent does not make it clear to you, I shall ask you to pardon me for again trespassing on you. The proposed studio is to be converted from a place already built, therefore reason of roof from floor to ridge being so high. As it is unnecessary to carry glass from eave up the whole length to ridge, how far up would you suggest it to be carried? If I carry glass four feet from background end, this will reduce me to eight and a half feet glass; would this not be too little to be confined to for groups? The light would be from the north-east."—We did not retain the sketch, therefore we have but a vague recollection of what it was. It would certainly not be necessary to carry the glass up to the full eighteen feet from the floor, probably not more than ten or eleven feet, even for groups. But we can give no definite opinion from the data before us.

ENLARGING.—HAND CAMERA says: "Referring to your report on p. 746, 'Enlarging Simplified,' do you think such an apparatus could be adapted to an ordinary hand camera, with lens in a focussing jacket? The black part of the sketch is the plan of the camera, and what I proposed was to make a square tube the size of the negative to push into the camera with the lighting apparatus, as described, at the rear. But what I cannot discover from books of reference is whether it will work with a hand camera. The lens is in a focussing jacket, but is it necessary to have a bellows camera to extend to considerable lengths?"—Such an arrangement as shown in the sketch will answer very well, provided the camera will lengthen sufficiently to enable the lens to be placed far enough from the negative. If not, a cone or extension will be necessary on the front of the camera. On this point, consult the table of enlargements and reductions on p. 1092 of the ALMANAC for the current year.

SPOTS ON PRINTS.—CLUTHA says: "Can you give me any information re marks on enclosed prints? They are matt a.c. platino-toned. The marks do not appear until the prints are mounted and dry, and in some cases two or three days after being mounted. Have tried everything before putting the blame on to the mount, but have come to the conclusion it must be the mount that is at fault. Have only just got the mount, and had no trouble before starting to use this mount, and prints from same batch, mounted on other mounts, show no trace of the markings, so can see no other cause to put them down to but the mounts. Have enclosed some of mounts without prints."—Without testing the mounts, which we have no time to do, we can express no opinion upon them; but we see no reason to suspect them, inasmuch as two of the spots show unmistakable evidence of careless manipulation. They are decidedly finger marks, while the finger was contaminated with some injurious matter. Of the finger marks there is no question whatever.

for constant reference, a fund of technical knowledge which is not to be found in any other photographic annual.

\* \* The 1899 Edition of the Almanac (20,500 copies) was entirely exhausted within three months of publication—a fact without precedent in the history of photographic publications.

## EX CATHEDRÂ.

THE catalogue of the second Philadelphia Photographic Salon, an Exhibition which closed on the 19th ult., has been sent to us. Besides giving a list of the 350 exhibits, the catalogue includes twelve half-tone reproductions from the photographs shown. Of the twelve, the majority are old friends in this country; and the work that is new to us, if good, is not exceedingly striking. The catalogue tells us that "the purpose of the Salon is to exhibit that class of work only in which there is distinct evidence of individual artistic feeling and execution." Thirty-one out of the 120 exhibitors were specially invited by the management to exhibit without submission to the Jury.

\* \* \*

PROFESSOR R. W. WOOD, of Wisconsin University, writes to Sir Henry Trueman Wood that he hopes to be able to let the Society of Arts have his promised paper on the "Diffraction Process of Photographing in Colour," by the end of February. Professor Wood hopes to come over himself; but, as he is not quite certain to be able to do this, he promises to send, in any event, a communication, together with specimens of the pictures, and a number of viewing instruments. He is hard at work on the process, and has overcome some of the initial difficulties. His principal difficulty now is to get perfect gratings ruled to arbitrary spacing.

\* \* \*

IN our issue of the 17th ult. we referred to the report of the Chief of the Fire Brigade of a serious explosion of what was said to be six pounds of chlorate of potash, by which seven persons were injured, four of them seriously, and at the same time we made some comments on the report of Colonel Ford, Her Majesty's Chief Inspector of Explosives, with reference to the lamentable catastrophe at St. Helens. In this report the

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE Thirty-ninth Annual Issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC is now published. The volume reaches the unprecedented total of 1516 pages, and is the largest yet produced. As hitherto, it is issued in paper covers, price 1s.; cloth bound, 1s. 6d.

The frontispiece is a bromide print by Messrs. Wellington & Ward, of Elstree, from a negative by Mr. H. Walter Barnett, of No. 1, Parkside, Knightsbridge. Many other illustrations are also given in the text matter.

Eighty articles, on a great variety of subjects interesting to photographers, and contributed by the principal authorities of the day, form a feature of the volume. The other sections are "Epitome of Progress during 1899," "Patented Inventions of the Year," "Miscellaneous Information," "Practical Notes and Suggestions of the Year," which, with the large collection of formulæ, tabulated matter, and a great deal of other information of use to all photographers, places at their disposal,

Colonel said that under certain conditions "the salt is liable to explode." Since the accident at Dalston one of the injured has died, and an inquest was held last week, when a verdict of accidental death was returned. But at the inquest it transpired that the chlorate had been used in the manufacture of coloured fires, and probably it was an admixture, and not the chlorate by itself, that caused the accident. We have often cautioned our readers as to the dangerous nature of flashlight powders, used as an artificial light in photography, when they contain chlorate of potash or similar substances. According to an evening contemporary, the proprietor of the premises in which the accident occurred is to be prosecuted by the L.C.C. for contravening the Explosives Act, the penalty for this offence being one hundred pounds. Those who make flashlight compounds will do well to keep this Act, and its penalties, in mind.

\* \* \*

THOSE who possess genuine works by Vandyck in this country are naturally very proud of their possessions, and when they change hands they always do so at high prices, and often not to remain in this country. England, as represented by our National collections, is not by any means overstocked with Vandycks, although much of his finest work was executed here. We see by the Law Courts reports of last week there was an application in the Appeal Court with reference to the sale of some of the Peel heirlooms, in which a couple of Vandyck's works are included. It was then stated that, in the opinion of experts, these two pictures would not realise more than from six to seven thousand pounds, for in no case had a work by this master, at auctions in this country, realised more than 3500*l*. However, the present owner had been offered, privately, 11,250*l*. for them. Whatever Vandyck's pictures are said to have been sold for at auctions, we do know the *very* high prices that have been paid for them at private sales—much higher than that said now to be offered for the two in question. Mostly, when old masters are sold now, they go abroad, chiefly to America, and are lost to this country. Will this be the case with these two Peel heirlooms if the Court permits their sale, whether privately or at auction? Although our National and Municipal galleries are very devoid of Vandyck's work, the Queen has a fine collection of them, both at Windsor and at Buckingham Palace; but it is only at the former that the public have the opportunity of seeing them. The Court has since decided that the pictures must be sold at auction and not privately.

\* \* \*

ACETYLENE is certainly not gaining in repute. Another fatal accident with it has occurred, this time at a chateau in Brussels. It appears that the owner had installed an acetylene generating apparatus in a small tower of the building. The report says that the gas escaped from the reservoir, and the *concierge*, with the lady of the house, entered the apartment with a lighted lamp, when an explosion of the gas took place, killing the *concierge* and severely injuring the lady. The tower was also demolished. In this case it is clear that the acetylene was mixed with air in explosive proportions, and common coal gas would, under the circumstances, have behaved in precisely the same way as the acetylene did. There is, however, this difference, coal gas is not usually generated on the premises, whereas acetylene is; hence we hear of more accidents with the latter than the former. In the small portable apparatuses used for generating the gas for lantern purposes, if used with only ordinary care, there need be no danger; but we fear that these

frequently reported accidents will, to some extent, militate against their employment—and more is the pity—when ordinary precautions are fulfilled.

\* \* \*

It is somewhat a novelty to see a sailor using a camera and tripod stand. But we read that on the departure of our late Imperial visitors there was a German sailor in evidence to secure photographs of the event. It turns out that he is the same man who so successfully defied the Portsmouth police when the Royal party landed on their arrival here, and it appears that he was specially employed by the Empress to obtain views of the Imperial journey for her Majesty's private album. However, there is no little novelty in seeing a sailor at work with tripod and camera. It is said that the man takes away with him pleasing impressions of his stay in England, but regrets that the atmosphere here greatly militates against successful photography. This one can readily understand when it is considered that the visit was made in November, and the kind of weather experienced during the stay. Doubtless he has plenty of "atmosphere" in most of his pictures, though we doubt if that class of work is much appreciated in the Fatherland.

#### A NEW ACTION OF LIGHT.

FOR some time past considerable attention has been drawn to the subject of lightning flashes, and, more especially, to the form known as dark flashes, as seen on photographic negatives. Lord Kelvin has given a personal experience of how he saw dark flashes, which, however, were merely persistence of vision and tired retina effects. At the same time many negatives, undoubtedly genuine and non-faked, are in existence showing dark flashes, and the question has arisen, "How do they come to be there?" A thoroughly satisfactory explanation was given some little time ago, and has formed a starting-point for investigations by other observers. It is as follows: If a plate be exposed to a lightning flash, and then slightly fogged by light, the flash, instead of coming out on the negative as an opaque streak on a foggy background, is represented by almost clear glass; but, if the fogging is done before exposure to the flash, this curious reversal does not take place, and the negative appears just as it might be expected to do. A similar appearance can be produced when photographing an electric spark; but we have but the recent one we are about to refer to of experiments giving these reversed or Clayden effects by other means. A long illustrated article by Mr. William S. J. Lockyer appeared in *Nature* of the 12th inst., describing and explaining a number of lightning photographs, and recounting experiments with the spark from a ten-inch Apps coil with a pint jar in circuit. The spark negative possessed all the peculiarities of the lightning negatives taken under similar conditions.

In last week's *Nature* the subject is continued in a letter from Mr. R. W. Wood, of the Physical Laboratory of the University of Wisconsin, who describes a series of cleverly devised and well-carried-out experiments, which have led him to a conclusion from which it is difficult to escape, but which is one of the most remarkable in the records of the photographic action of light. This conclusion is of the highest importance, and we may expect to see it further dealt with by other experimenters.

Mr. Wood, like Mr. Lockyer, obtained the Clayden reversals when using a spark from an induction coil with a jar in cir-

cuit, but did not rest there; he tried to get reversals, from other sources of illumination. For some time he failed, though he used several sources of illumination, including an oxygen-hydrogen explosion, the light from which he estimates to have a duration of  $\frac{1}{12000}$  second. But that was not brief enough. Finally, by means of a revolving opaque wheel with a radial peripheral slit passing, at intervals of  $\frac{1}{60}$  second, a corresponding powerfully illuminated slit in an opaque screen, he was able to secure an impression representing  $\frac{1}{55000}$  second, which approximates to the rapidity of a lightning flash. The illumination of the slit consisted of a beam of light from an arc lamp focussed by a large convex lens of short focus. Here again he obtained reversal, and the remarkable conclusion referred to was forced upon him by the facts. Mr. Wood writes: "It seems, then, that we are justified in assuming that the action of an intense light on a plate for a very brief time interval decreases the sensitiveness of the plate to light." If this conclusion should be confirmed by other observers, it will be the beginning of an entirely new chapter of photographic action.

#### A RIVAL TO CELLULOID.

NITRATED cellulose has long held the field as the basis of a flexible glass, as celluloid has been called; but there seems a probability that before long Messrs. Cross & Bevan's invention, aceto-cellulose, may be found a formidable rival, for it possesses many advantages over the pyroxyline which, in combination with camphor, is the main constituent of celluloid. We learn from a foreign journal that the manufacture of tetracetate of cellulose has, during the last few years, made rapid strides, as also has the butyrate, which is a somewhat analogous substance, the substances being now produced on a large scale.

Perhaps the most conspicuous quality of the acetate, compared with the nitrate, is its non-inflammability—it burns very imperfectly. It differs further from the latter in that it is insoluble in methylic and ethylic alcohols, acetates of amyl and ethyl, acetone, and ether, but is soluble in benzoate of ethyl, chloroform, epichlorhydrine, acetic anhydride, glacial acetic acid, and nitro-benzine, the solution in the latter becoming a solid, completely transparent jelly. The solution in the other named liquids can be diluted with acetone without precipitation taking place. The aceto-cellulose resists most reagents in a remarkable manner. Dilute acids and alkaline dyes destroy nitro-cellulose, but, with exception of dilute nitric acid, do not act upon the new substance, in some cases even when boiling.

It is probable, too, that, used as a basis for films, it will be possible to dry them quickly by the aid of alcohol in the usual manner, a process quite out of question with celluloid, as any one knows to his sorrow who has tried it. The acetate does not change by the action of heat below 300° F. The hydrate of cellulose possesses very similar properties, but is more soluble in the liquids named, and is also easily soluble in acetone and in acetate of ethyl. The butyrate is very similar to the acetate, but the filaments formed from it are softer and more flexible. From all these facts the journal alluded to predicts that the new substances will be powerful rivals to celluloid, and especially in cases where non-inflammability is an important consideration. Finally, it is anticipated that they will form excellent lacquers for metal, their resistance to moisture, heat, and chemicals being far above that of the usual

basis; of course, any colour can be given to them that may seem desirable.

**Preserving Brasswork from Corrosion.**—The use of the old lacquers where moisture or chemical fumes are absent is very effective in preserving the appearance of polished brasswork, but in the case of delicate articles used in a laboratory, such as brass weights scale beams, and so forth, it has been the custom to gild the surface in lieu of lacquering. Recently, however, Mr. W. A. Allen, of the State School of Mines, Rolla, Missouri, has made public a case in which a set of such gilt weights put away in a box, but evidently in a damp condition, in a safe for less than three months, were corroded and covered with a white incrustation, and he raises the question whether gold-plated weights are, under ordinary working conditions, preferable to brass.

**Astronomers on the Missing Star Shower.**—It is very disappointing to every one, and especially the astronomers, that the long-talked-of and expected "shower" of meteors did not occur, at least in the night time, as is quite evident was the case, for in several places the possibilities of observation were excellent. When the last great shower occurred, our older readers may remember, considerable uncertainty as to the exact year when they were to be expected was manifested, and, in like manner, on the present occasion, as our previous remarks have narrated, a similar absence of certainty was felt. To avoid complete disappointment, we may say that skilled astronomers still bid us hope to see the "shower" next year. The Rev. C. L. Tweedale writes to the *English Mechanic* that he thinks we shall have the pleasure of seeing the shower next year, and under much better conditions than those prevailing on the recent occasion. There will, of course, then be no moon to interfere with the apparent brilliancy of the display. Then, also, Mr. W. F. Denning writes to *Nature*: "There is every reason to suppose that, though the shower has managed to elude us this year, it must confront us next year, and possibly in 1901. . . . But many of us will hope to find compensation for the disappointments of recent years in observing a brilliant return of the meteors in one of the two ensuing years, and certainly before the denser region of the stream gets too far on its outward journey to aphelion."

**Purification of Acetylene.**—This question, which is of increasing importance, has occupied the attention of many investigators for some time past, and will naturally grow in importance as the use of the gas becomes more general. In a recent number of the *Engineer* an exhaustive article on the subject was given, and the merits of the various systems dealt with, the summing up of the results being as follows: We see that, by keeping the original acetylene free from too much moisture, removing the ammonia, treating it with chloride of lime, diluted, if necessary, with some inert inorganic substance, and making it afterwards pass through a vessel of soaked lime, more of the impurities in the crude gas are extracted than if the Frank or the Ullman process be adopted. The operation is said to be simpler for a non-chemical attendant; it is obviously far cheaper. The one disadvantage of the purified gas, its minute percentage of carbonic oxide, is too trivial to be considered.

**Electric Seeing.**—Some few months ago much interest was roused by the publication of an account stating that Mr. Steins had discovered a method by which, with the aid of electricity, blind persons could be made to see. Naturally such a plan had photographic interest from possibilities it foreshadowed in connexion with photography. But the bubble has been pricked by Mr. G. H. Robertson, who himself is blind, and who has communicated the results of his inquiries to the *Electrician*. Briefly, he made personal inquiries, and, notwithstanding several visits to Mr. Steins, no experimental proof in substantiation of the claims which were put forward on his behalf were obtained, and the conclusion arrived at is that these claims were without foundation.

## JOTTINGS.

THE prospects of British photography being worthily represented at the Paris Exposition do not look bright. By British photography I, of course, mean all branches of photographic production—not merely “pictorial” photography, which a very eminent figure in the photographic world recently declared to me to be relatively so unimportant, in comparison with other branches, that, if the “whole boiling of it” (his words, not mine) were swept away to-morrow, it “never would be missed.” Some of it would not, at any rate; and so far we are in agreement. But to the Exposition: the pictorial and technical works which Mr. Craigie and General Waterhouse are to send to Paris would about fill one of the small walls at the Pall Mall Gallery, so that, however carefully the selection is made, this display can scarcely be considered representative.

And, if British photography is to be inadequately represented at Paris, British photographic manufactures are likely to share the same fate. From an article in *Engineering*, which was probably written by that great Exhibition authority, Mr. James Dredge, it appears that British industries and science will only be represented by 642 exhibitors! Of that number it is obvious that very few indeed can be photographic manufacturers. The writer of the article is of opinion that “possibly this apparent indifference is partly due to the remarkable absence of information available about the Exhibition, and partly because of the unsatisfactory arrangement, from an exhibitor’s point of view, by which exhibits will be scattered over a large area, instead of being concentrated into a British section.” Other causes which need not be referred to here may have been at work; but, whatever is at the bottom of the matter, there is no escape from the fact. However, if British photography makes a poor show at Paris next year, we may confidently expect that nearer home, in 1901, it will make a brave and notable display. I am alluding to the Great International Exhibition at Glasgow, which takes place the year after next.

I notice that Mr. Bolas, in the course of a discussion on stripping films at the Royal Photographic Society a few weeks ago, contributed a useful note on the history of daylight changing. He said that for many years he considered himself the originator of the “daylight cartridge” system, which he described at a meeting of the South London Photographic Society in, he thought, the year 1886; but he (Mr. Bolas) found quite recently that in a number of *Notes and Queries*, issued in 1855, the system was described in very full detail by an Indian officer, Captain Barr. All honour to Mr. Bolas for having so publicly waived his claim to priority. It would be interesting to know if Captain Barr is still alive and a witness of the immense esteem in which the convenience of daylight changing is held by hundreds of thousands of photographers.

Ortol appears to be the reigning favourite amongst the new developers, if we may judge by the amount of attention it is receiving at societies and in the press. I remember submitting it to experimental trial on its first appearance and being much impressed with it, but after a couple of years one’s recollections of the characteristics of a new developing compound can hardly be expected to be very vivid, so I have forgotten ortol’s points. And as to the last word—points—my experience is that the points of resemblance between modern developers vastly outnumber the points of difference. Will anybody undertake to differentiate between, let us say, diphenal, diogen, and imogen? As to ortol, my object in penning this paragraph was to say that the most striking evidence of its value in certain classes of work was submitted to me a little while ago by Mr. Walter Everitt (no relation to Philip of that ilk).

Mr. Walter Everitt is a portrait photographer of surpassing ability, who has only to exhibit his work to be sure of making his mark. He showed me a series of clever studies, the subjects being ladies photographed in very soft, indirect, well-diffused light. The ladies’ dresses were of light silky materials (I’m no man milliner, so I can’t give a more precise description), but they were of delicate, shiny fabrics

which, in a soft light, would be full of the most subtle gradations Mr. Everitt first showed me a series of prints from pyro-developed negatives which excited my admiration; in fact, better renderings of flesh tones and gradation of light and shade I could not wish to see. However, when some duplicate prints from ortol-developed negatives were next produced, I was exceedingly surprised at the difference, the ortol prints betraying a purity and minuteness of gradation not visible in the pyro prints. I do not think I have seen more perfectly modelled and harmoniously lighted portraits than those I am referring to. Hence, possibly for the finer classes of portraiture, ortol may have properties worth the trouble of photographers to put to the test.

Rumour is very busy just now with all sorts of suggested “com-bines,” possible and impossible. I have heard it said that professional photographers are to be invited to unite for the purpose of getting better discounts off plates, papers, &c., than they are at present allowed. The chances of unity in this respect are, it may be supposed, rather slight, for the professional photographer seems to be like the Dunderbary bird which only “flocked” all by itself. And it is “all by” himself that the photographer appears to prefer to combine. If there is no combination or unity in defence of copy-right, the right to the negative, the suppression of price-cutting, and other vital things, you may safely conclude that increase of discounts will not prove the most inspiring and successful rallying cry. But, if the movement is started, it will be watched with interest and sympathy by many, no doubt.

Then, there is the other rumour as to an imminent amalgamation of some of the plate and paper-manufacturing houses. The man in the street has gone so far as to mention names. I shall be surprised, however, if the combination takes place. As I pointed out while writing on this subject a couple of months ago, the Continental manufacturers are only a few hours’ journey from the home market, and a limitation of the sources of English supply would inevitably be followed by a very keen foreign competition; while I am not sure that such a combination, if it was formed, would not also have the effect of unlocking British capital for the purpose of starting plate and paper factories here at home. Considering the number of fortunes that have been made in the business during the last few years, it is surprising that more Richmonds have not entered the field.

Even in the United States, the home of trusts and combines, the latest photographic combination, viz., that of the General Aristo Company, is not escaping opposition and competition. A friend, writing from the other side, tells me that, notwithstanding the “pull” enjoyed by the uncoated paper trust, two kinds of German baryta paper are being placed on the American market. If these papers answer the purposes of the sensitiser—which, of course, has to be seen—then the American trade in gelatine, collodion, and other papers will be once more split up. The old copy-book maxim used to tell us that competition is the soul of trade. Modern British trade is a very “soulful” thing indeed, for it never was so keenly competitive—or perhaps so prosperous.

As regards British photographic manufactures, it is doubtful whether the talked-of “combination” would be successful. Photography, after all, is a very small industry, and has not yet reached that stage when demand exceeds supply, so that the competition which such a combination would surely provoke might bring about a glut in the market, with its many attendant evils. A kind of Pattison’s whisky case over again.

As we are so near the festive season, this is a fitting opportunity to acknowledge a kindly invitation sent by the Editor of *Wilson’s Photographic Magazine* (New York), one of the most beautifully illustrated publications in the States. *Wilson* says: “The Editor of *THE BRITISH JOURNAL OF PHOTOGRAPHY* thinks that ‘American Conventioners’ ‘do themselves’ exceedingly well.’ But he is very

anxious to know more about that clam-bake. Words cannot describe it, but he will find a hearty welcome if he will come over next year and learn bliss by experience." The Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY asks me to very cordially thank his American *confrère* for his graceful compliment. I am also to add that next year the one insurmountable obstacle to his learning the bliss of clam-bakes at the American Convention is a prior engagement at the British Convention, Newcastle-on-Tyne, where he has no doubt various other kinds of bliss await him.

COSMOS.

### THE NASCENT SILVER AND SUB-HALOID THEORIES.

[Translated from the *Archiv für Wissenschaftliche Photographie*.]

UNDER the above title Herr G. Mercator has recently discussed, in a very comprehensive manner, the grounds upon which I base my preference for the view that the latent photographic image is formed of nascent silver rather than sub-haloid. Mercator comes to the conclusion that, in the absence of more cogent reasons, he must regard the sub-haloid theory as the more simple and safe, but he does not cite one single experimental fact which may be explained by one theory or the other exclusively. Whether one theory or the other be more simple and safe is evidently an affair of personal taste, and consequently not matter for scientific controversy. Were it not that he had incorrectly stated some of my arguments, and asked a series of questions to which I feel indebted to the nascent silver theory for reply, as against one-sided answers (*sit venia verbo*) in favour of the sub-haloid theory, I should not feel any inducement to reply to Herr Mercator. But I will also avail myself of the opportunity to balance one theory against the other by the light of a few fresh experiments.

As it is the duty of science to collect the whole of the facts within as few theories as possible, of two theories which account for a given phenomenon that must be taken as the better and more useful which explains the larger number of phenomena besides the one in question.

Of the two theories in question, the nascent silver theory is the more comprehensive, as it embraces the latent image and the processes of physical and chemical development, whilst the sub-haloid theory has not hitherto been used, or at most unsuccessfully, for the simultaneous explanation of development.

If, therefore, the nascent silver theory suffices to fully explain all that we know concerning the latent image, it should receive our assent in preference to the sub-haloid theory, unless it is thought that a theory should be absolutely true, rather than the shortest mode of expressing our experience. It is, consequently, the true scientific attitude to follow the nascent silver theory to its utmost consequences, since it is indispensable for the processes of development, and only there to relinquish it and seek a more satisfactory one where it fails to account for facts.

No facts could be brought forward, which were inconsistent with the nascent silver theory, when I recently stated my views for it in preference to the less useful, and therefore superfluous, sub-haloid theory. My reasons were not fully stated, but self-evident to the careful investigator. On the other hand, I cited the marked reduction of the latent photographic image by the action of nitric acid as inexplicable according to the sub-haloid theory.

In opposition to this, Eder has recently brought forward experiments showing that a weak yet developable image may be obtained by exposure upon collodion emulsion sensitised in a bath strongly acidified with nitric acid. According to my opinion, the diminution of capacity for development, as shown by this experiment, proves that at least some part of the substance of the latent image is dissolved by the acid, and may be metallic silver, rather than sub-haloid. We cannot infer from Eder's communication if the film with which the plate was coated contained sufficient acid to dissolve, under such circumstances, the whole of the silver which may have been formed by the action of light. Were this, however, the case, the experiment would also prove that some other part of the latent image is insoluble in nitric acid, and therefore not formed of metallic nascent silver, but very probably of sub-haloid, if the latter be insoluble in the acid solution referred to. This conclusion of Eder's, however, is confined to a portion of the latent image, and, when it is established that the quantity of acid used was sufficient to dissolve the metallic silver, I will acknowledge it, and concede that the nascent silver theory is insufficient to account for the latent image. But at present, as in the past, it suffices to account for ascertained facts, and, on the ground of economy of hypotheses, there is no adequate reason for acceptance of the sub-haloid theory. But, notwithstanding this funda-

mental principle, we cannot prevent the formation of hypotheses *ad hoc* to account for most of the new facts, in preference to trying to include them under the old theories.

In reply to "Mercator's" arguments, I wish to state that I did not assert that the existence of sub-haloid cannot be proved, but that it is *merely indicated*; also that sub-haloid *may* be, not *must* be, regarded as a mixture of normal haloid and metallic silver.

It is unnecessary to explain that silver, as well as sub-bromide of silver, may be converted to normal bromide by means of bromine. Herr Mercator has, however, to prove that a solution of potassium bromide can part with sufficient bromine to bromise a finished negative before he is entitled, under this tacit but incorrect assumption, to contrast the destruction of the traces of silver forming the latent image with the failure to bromise the whole of a finished negative.

It is quite easy to understand that other acids "which are not solvents of metallic silver" destroy the latent image formed by light. Herr Mercator means, of course, acids which have no marked microscopic action upon metallic silver; but the minute quantity of silver forming the latent image may be dissolved notwithstanding, for there is no such thing as absolute insolubility, according to fundamental physico-chemical laws.

I have already explained that a highly sensitive emulsion contains more nascent silver through ripening. Starting with this idea, I have since arrived at results which, though as yet qualitative, harmonise well with experience.

I may remark, in passing, that the nascent silver theory has thus acquired a certain amount of justification as a working hypothesis, whilst the sub-haloid theory can only show a very barren past.

Light adds nascent silver formed by exposure to that formed in the process of ripening, and the normal bromide supplies material during the process of development for the production of further nascent silver, which with the former constitutes the finished image. The action of bromide of potassium prior to development has already been explained. I do not find any difficulty in the way of the nascent silver theory giving these answers to Herr Mercator's questions; but, on account of our difference in taste, it is impossible to decide whether the sub-bromide answer given by Herr Mercator is more satisfactory and simple, with its "sub-salt of unknown and unstable composition," which "finally reaches a certain condition." I have a preference for the nascent silver reply, but its impartiality will not be readily acknowledged.

Herr Mercator throws out an important question in his explanation of solarisation.

According to him, the sub-haloid theory assumes that spontaneous oxidation occurs if there is a greater loss of bromine than is necessary to arrive at the stage of development. If anything is an hypothesis *ad hoc*, we have it here. To add to the hypothetical sub-bromide of variable composition another very hypothetical oxybromide, to which the highly improbable property of irreducibility by the developer is ascribed, this can have no scientific claim of value so long as the existence of such a substance is merely assumed for this particular purpose. This "explanation" is, however, rendered impossible by the fact that solarisation also takes place in the absence of oxygen, consequently where oxidation is precluded. Luggin's experiments have proved this conclusively.

Solarisation might be explained in the following manner by the nascent silver theory. Prolonged exposure to light reduces so much metallic silver that the particles of silver haloid from which it is derived become enclosed and protected from the action of the developer. A proof of this assumption might be obtained if a plate were exposed till solarised, then fixed and developed physically by Kogelmann's method. According to the nascent silver theory, a normal negative, not a solarised negative, should result. At present our supposition is favoured by the fact that all solarised negatives are veiled. Consequently development takes place all over the plate, which agrees with the deduction from the nascent silver theory that, in consequence of exposure, nascent silver is present over the whole film.

Mercator also doubts that metallic silver exerts any specific developing action, but this has been proved by me and by Herzog. The circumstances cited to the contrary, that other substances besides metallic silver induce development, does not dispose of the fact to a logical mind that nascent silver acts similarly. Moreover, it has often been shown that influences causing fog, such as pressure, contact with paper, certain gases, &c., are, without exception, those which bring about a reduction of silver from silver haloid, and therefore generate nascent silver.

That the transition of the sub-salt of the exposed and undeveloped plate to the metallic nascent silver of the finished negative should present difficulties to the mind of Herr Mercator is a matter for congratulation.

lation, for the nascent silver theory avoids this conception of transition. Concerning the opinion to which Mercator then gives expression, I can only endorse the query of the editor, for it seems to me a fact beyond discussion that an image formed of nascent silver may be strengthened by nascent silver already present in the film.

Mercator's explanation of Abney's experiment implies that the bromine of the normal bromide and the sub-bromide will attain an equilibrium by diffusion. This presupposes that unexposed silver haloid possesses a distinct partial tension of the halogen, which is contrary to all physico-chemical experience.

Abney's cyanine experiment may be explained by the nascent silver theory as easily as Mercator can explain it by the sub-bromide theory. The reducing action of exposed cyanine, which the latter assumes, is the cause which generates nascent silver from the silver haloid, and thus brings about capacity for development. This offers no apparent difficulty.

Mercator's conclusions concerning the grain of plates lack the proof of his premises, that more equal reduction should occur in the presence of a large than a small quantity of nascent silver. As opposed to this, I have endeavoured to thoroughly explain the connexion between the grain of the plate and development according to the nascent silver theory in my article on "The Theory of Photographic Development."

The fact that I only recognise a purely superficial difference between physical and chemical development seems extraordinary to Herr Mercator. Evidently this is from not being familiar with the experience that a free state must precede the deposition of a solid substance, and that deposition takes place from the solution where solid substance is already present. Ostwald was the first to draw attention to this analogy between the mechanism of development and the process of crystallisation, and Schaum has recently again explained it. In physical development the silver image grows outwardly, because the silver is added from outside to the nascent silver. In chemical development the image is an inward growth, because the film only contains silver. This is the only difference, which clearly is not essential in its nature. I willingly admit that the chemical development of a wet-collodion plate and the physical development of a gelatine dry plate are both possible according to the nascent silver theory, but I am not aware that they are practical impossibilities.

Mercator's conclusion is not permissible, that metallic silver is distinctly soluble in hyposulphite of soda, because prints lose considerably in the fixing bath. Unfixed prints are mostly formed of coloured organic silver compounds and organic colouring matter, produced by the action of light upon silver haloid mixed with organic substances. These are soluble in the fixing bath.

I tender these proofs in opposition to those of Mercator, and think they are preferable, because the conception is that of chemically and physically defined metallic silver, and not an ill-defined sub-salt.

R. ABBEG.

#### WINTER PRECAUTIONS.

We have now arrived at the second week in December, and it is not too soon to take a few timely precautions against the inconveniences often experienced by photographers in winter, particularly when we have a "real old-fashioned winter." One of the greatest inconveniences to photographers is a frozen water supply, and when that is experienced most can realise how easily it might have been avoided if they had only thought of it beforehand. A pipe soon freezes, but it sometimes takes a long time to thaw again, as witness the winter we had a few years back. Therefore, as a reminder, we should recommend all who have outside exposed pipes to lose no time in protecting them. A special felt is now sold by most ironmongers for the purpose. Two or three thicknesses of this wound round the pipes affords them protection, even in very severe weather. If the service pipe is laid near the surface of the ground, a few inches of good stable manure spread above will afford it ample protection. Up to the present we have had no indications of a severe winter, or, indeed, any winter at all, but with our uncertain climate no one can tell how soon one may set in. Even if the precautions alluded to prove not to have been required, they involve but little trouble, considering that they may be the means of saving. Hence the hint, and a reminder of the old aphorism, "A stitch in time," &c.

#### THE RELATION OF PHOTOGRAPHY TO ART.

[Transactions of the Edinburgh Photographic Society.]

THERE is a saying of the *Autocrat of the Breakfast Table*, the gist of which is that, for the purposes of conversation, it may be profitable, and it is necessary, to have a common understanding of the meaning of

terms. The confusion current in the use of terms relating to art does not make my task an easy one. A photograph is sometimes spoken of as a picture, and in the context may be rightly so denominated. Again, a picture is recognised as a work of fine art, and then there has arisen a fashion of talk of a decorated panel, so that in speaking of things the objects and purposes of them are lost sight of and obscured.

Whatever a photograph is as a final result, it is in the first place an impression thrown on a sensitised plate, and fixed by chemical means. Given that you have a perfectly flat object, such as a black-and-white picture or a bank-note, you may have a perfect reflection, perfectly fixed, but it is not the reproduction of such things that we are to discuss.

It is said that it is good to find out one's own limitations, and to direct our exertions within them. For that reason, if for no other, I would call your attention to the limitations of the photograph; but I do so quite as much because there is a very common understanding that a photograph gives an absolutely true impression, corresponding to the impression received by the eye, except in respect to colour.

A friend of mine told me the other day how he photographed sunsets. "That," said he, "is how we get moonlights." Thus this supposed absolutely true impression comes by the time it is printed to resemble a moonlight, and to be used as such. How this comes about I have no doubt all of you know who have any practical acquaintance with photography. You know that, as the afternoon runs into sunset, your plates become lower and lower in tone, and a longer and longer exposure is necessary in order to fix the form of things with any degree of fulness. All the time there is a certain unity of tone within the photograph, whether the form is clear or vague. This unity has no relationship with the appearance of things as the eye sees them, but is in accordance with the strength of certain rays which emanate from objects and act in accordance with laws of their own, so that at a given time of day, and by a limit of exposure, you may produce a picture that may pretend to be a view of the night. I use this illustration to show that the impression goes wrong in the fixing. The forms are in many respects true, but the general appearance is so altered that day has become night. There are other appearances—knowing the appearance intended to be reproduced—that are as strikingly at variance with the appearance as the eye sees it, notably groupings of foliage, which are never reproduced approximately to the appearance as the eye sees them. Now, this departure from a true appearance, which is striking and obvious in these instances, is present in all photographs. I have seen a photograph taken pretty late in the afternoon of a grey day which, by long exposure, realised, by the fulness of the modelling and discrimination of distances, the ideal of "plein air," so much sought after by a certain school of French artists of twenty years back, of whom the greatest was Bastien Le Page, whose work many of you may have seen in the recent Exhibition. But this photograph did not give anything of the character of the day on which it was taken, and this is notably the character of photographic work, the tones of which, however subtle, are not those tones related to natural appearance which enable us to distinguish between day and day. Looking to what I have said, I would therefore define a photograph as an imperfect impression gone wrong in the fixing. Finally, the difficulties of giving a perfectly natural appearance are not overcome even in a photographer's studio, however cunningly contrived, but come out in the undue force given to wrinkles and freckles. This undue force is well recognised, the reason being that, if you give an exposure sufficient to give a just appreciation of the part of the face in shadow, you will have over-exposed for the light.

If there is a departure from a truly natural appearance through the impression going wrong in the fixing, there is also a great and most subtle departure from the natural appearance of things through the peculiar perspective arising from the impression being thrown on the plate in the camera. Every one knows how out of proportion objects in the immediate foreground look. That is simple, but it does not end there. It is, indeed, the most obvious sign of a subtle distortion. I have seen most extensive views, say, of Campbelltown Bay and places like that, without objects in the immediate foreground to arrest the attention, which, knowing the places, have taken me by surprise. There, sure enough, are all details—the pier, the houses, the hedges—all right enough, but the general impression of the whole is of a place much more vast. Again, we have been made familiar with the apparently lordly palaces which many of the prominent literary and artistic workers inhabit, but this perspective of the camera has a trick of enlarging the contracted in rather a strange, and, I confess, in altogether a pleasing way. On the other hand, high places are sometimes brought low; thus ranges of hills in mid-distance are always very disappointing. Much more subtle is the distortion in a full-length figure occupying the larger portion of the photograph. I have noticed that the photograph is rarely used to show the fashion in the garments of women, and I do not wonder, for, unlike the view of Campbelltown Bay, which idealises, the full-length view of our lady friend rarely gives us the elegance we know she has. A review of the theatrical personages shown so largely in *Black and White* and the *Sketch* cannot, I think, fail to bring home the truth of this.

I bring these things before you, not in any wise to belittle photography, but because, as I said, of prevailing ideas attributing absolute truth to the photograph—and partly and more particularly as bearing upon our subject to inquire into the limitations of photography—for it is this

power imperfectly to fix an imperfect impression that you have to handle and apply to art or other purposes. Whatever the imperfections may be, it is a great power, because of its accuracy within limits and its ease of production, thus reaching millions, and giving information to millions, on all sorts of subjects, who would otherwise be uninformed.

As to the relation of photography to art, I have alluded to the confusion of terms relating to art, and have thought that if I gave you the idea of the purpose of art as expressed by one of the greatest artists, and some ideals as expressed in a word or two by others, we might get more readily to the heart of things than by a disquisition on terms that would necessarily be long. "By art alone," says Hokusai, a great Japanese artist, of whom Whistler speaks in the highest praise, "can we perpetuate and transmit to our descendants, and to our brother removed from us by a thousand leagues, all the joy and beauty we see filling the universe, the things of heaven and of Buddha, the life of men and women, of birds and beasts, ay, of trees and herbs." Again, I remember hearing Paul Chalmers, in presence of what to him was the exquisite beauty of nature, express the desire to have the power, not to paint it, but to be able to blow it on to his canvas. No more was said; I had understood him. I knew everything was passing so quickly, the very emotion was passing even as the incident that raised it; and the knowledge of this, and the sense of the perfection of things as they appeared in all their manifold unities, made him use the expression that he would like, by a breath, to have thrown the impression upon the canvas.

I have chosen this idea of the purposes of art as expressed by Hokusai, and this aspiration of Chalmers, as being such that the photographer might most readily lay hold of and associate his work with. Observe the all-embracing nature of the outlook of Hokusai—not merely the things of heaven and of Buddha, but "the life of men and women, of birds and beasts, ay, of trees and herbs." Surely the photograph should be able to tell us of some of these things as nothing else can. In a book by Rudyard Kipling, called *The Light that Failed*, he outlines, with singular ability, a man notable as an art student, the crack student of his year, who comes to nothing, never having what he calls conviction. Taught to paint, and with power matured, this man finds nothing to do. To him the world was not filled with joy and beauty, and no burden was laid upon him to perpetuate it. Without this "conviction" the photographer will, as an artist in photography, fail, even as this trained painter failed. If I am understood, you will see that I consider the most important thing in art is the motive. On the method I may have my opinion, and I preserve the right in common with everybody to judge of work accomplished, whether it is what it pretends to be, but the vehicle of the thought or the method is in the hands of the individual, and should it appear to any one that the photograph is the most fit instrument to articulate his emotion, that nothing else will accomplish his purpose so well, I wish him God-speed. I say articulate his emotion. Art is always emotional; in taste, its most elementary form, what is it but an emotion, a sense of rightness arrived at through feeling? Reconsider the words of Hokusai—it is no scientific knowledge of things that he desires to preserve, but the joy and beauty of them. It is no mere record of person or place that is at the basis of art work, but, at the very least, an appreciation of ideals and harmonies.

In the early days of photography certain work of a notable character was produced by D. O. Hill. Recently there has been some talk of a collection and republication of it, which I hope will be gone on with. It is the work of a man obviously trained in and with a knowledge of the best traditions of art, with great original power of conception. On the old lines of pictorial construction, one finds in these photographs beautiful arrangements of masses of light and shadow, constituting designs of a large and significant order; and, though you may single out one which you may prefer, this character runs through them. In the face of such work, one must acknowledge that the photograph may be made a vehicle for art expression of no mean order.

"Art is long and life is short" is one of the oldest sayings, and I do not think that the photograph really shortens the way of art. Suppose you form any ideal, if that ideal is a worthy one, you will make many attempts, and then it will not be realised, but a sort of approximation will be arrived at, and, with all sorts of regrets, you will give it to the public. If it be an art ideal, concerning the life of men or women, of birds or beasts, of trees or herbs, of groupings of light and shadow, then all past art will have some lesson to you as to how you will place or arrange your thoughts. The method, as in the operation of the photograph or the particular handling of the brush, becomes relatively a detail.

Although we have been considering the photograph as a possible medium for the production of original art work, that such is its primary or general application I do not concede. The general use made of photography, which is, also, I think, the most natural, is to show persons or things, not to express sentiment about them. For the purposes of knowledge, this power of fixing an impression even imperfectly of objects changing every moment is invaluable. Within our own time it has revolutionised our ideas of the action of animals. Through photography we now know absolutely the position the limbs of animals have in relation to each other in the process of a movement, birds as

well as beasts. Since this revelation artists have modified more or less their conventions expressing the movements of animals.

It must be remembered, however, that each individual photograph does not show motion, but arrested motion. What is done in art, where it is successful, is to express more or less by a convention the idea of motion. The rudest convention, portraying, say, a whirl of drapery or a falling wave, is infinitely truer, and, because truer, more beautiful, than a photograph of the same with its portrayal of arrested action. I have spoken of the tones of the photograph as not being true to the tones of nature as seen by the eye, being the product of the action of certain rays that act in accordance with laws of their own, and I would be sorry to see ideals founded upon such a false basis dominate us in our notions of truth. It has been said that the delineations of features as given by Reynolds and Raeburn are beautiful generalised conventions, and they have been opposed to the work of more recent painters as being less true, if more beautiful. I do not think so, but rather do I think that they are more beautiful because they are more like nature, and less like photographs, than the work of these more recent men. I think the truest aims of art have ever been, in all conditions of knowledge, to express the joy and beauty of the world around us, and the attainment of these ends never requires the sacrifice of truth.

I have referred to the influence on art of the knowledge of the movement of animals imparted by the photograph, but there is a movement in almost everything that has life—movement embarrassing to the student, movement in clouds, movement in the growth of herbage, changes so rapid that, before you can record the present appearance, the appearance is gone, so that this power of fixing even imperfectly the imperfect impression of a passing appearance is an enormous help for the purposes of knowledge. And, beyond this, there is also to be remembered that the faculty of delineating appearances is not bestowed upon every one, so that this photographic eye that takes with it the power to make a permanent image—which any one with a few shillings to spare may have—is not to be despised, even although it may be an imperfect one, for by this new eye the number of trained observers may be enormously increased. There have from time to time appeared photographs of birds' nests taken in almost inaccessible places. Few things in photography are, I think, more beautiful. Besides the interest of them, they have also something of the relation to art that the direct artless tale has to imaginative literature; but it is the pursuit of knowledge, not the appreciation of the beautiful, that is their *raison-d'être*. This pursuit of definite knowledge, which has such a happy result in the instance I have mentioned, might, I think, more frequently be followed, and would, I think, take the place of what Kipling calls conviction in art proper. It is not in this or that, but anything almost might be your subject. Say to relate the form of clouds one to another; the form of clouds when the wind is blowing from the east; and the different form they take when the wind comes off the west, or in a gale, noting the rate the gale is blowing at. Like the chemical experiments in crystals, I think you would find that the most beautiful forms would be evolved. This would certainly require patience, and something more, but the results would be an added interest to the work of photography.

There is a kind of art called archaic. That name is applied to the work produced when the laws of perspective were unknown—when the laws of chiaroscuro were unknown. The laws relating to these things were not unfolded all at once. If you go back far enough, you find art wholly archaic, but coming down from such a period you find degrees of archaicism. This lessening archaicism, due to increase of knowledge, is sometimes mistaken for art progress, but that it is rightly so called I greatly question. It appears to me that the artist works in the atmosphere of contemporary knowledge of fact. I am told that at this moment there is an utter breaking up of the traditions and conventions of art in the East. Various reasons are given for this breaking up, and probably there are various causes in operation; but among all the possible reasons the major one will remain, that you cannot take the knowledge or the science of the West to the East without this knowledge reacting on the art of the country which receives the enlightenment. It may be, therefore, that the enlarged knowledge of the facts of appearances due to the photograph will react upon pictorial art, but this added scientific knowledge will not make the picture more artistic, that must depend on the power and emotion of the artist alone.

Great inventions have been called great gifts to humanity, and I think the photograph may well be called a great gift. At the same time, like many another gift, it is not without its dangers. I remember hearing a remark by an artist who occupies still, and has occupied for a long time, a foremost place as a draughtsman. He said that, when he saw younger men coming forward, he sometimes feared for his position; but, as he saw one after another making use of the photograph to copy its forms, his fears vanished, for, as draughtsmen, he found that, from the moment they began making this use of the photograph, they ceased to develop as draughtsmen. The reason of that, I think, is simple enough. A faculty will just maintain itself and develop by the legitimate use of it, and a draughtsman, copying from a photograph as an easier way, releases the strain of his endeavour, and, in doing so, loses his power. Such a use of the photograph is a danger to the artist. And I think that the common understanding, to which I referred in the beginning of my paper, that the photograph gives a true impression corresponding to the

impression received by the eye, except in respect to colour, is having evil effects on certain ideals of art; and for this reason, while accepting photography as a great gift, I would ask for the keenest scrutiny into its limitations.

J. LAWTON WINGATE, R.S.A.

### CINEMATOGRAPHY AND THE PRIZE RING.

THE well-known authority on sport, Mr. Martin R. Cobbett, has the following remarks, in the *Referee*, on some curious aspects of the association between animated photography and the American prize ring. "We are promised that a moving picture report of the Jeffries-Sharkey glove fight shall be shortly on view in this country. From what the only genuine electric photography firm say about the opposition, who endeavoured to poach pictures of the two boxers in action, Mr. Dion Bouicault was slightly in error in putting the camera at the same weight as George Washington as a truth-teller. Trade jealousy is responsible for the statement that the instrument can lie, and on that account the public, possible customers for the only veracious, genuine article, have been given notice to see that they get the proprietary article when they ask for it, and not to be imposed upon by more or less colourable imitations. I do not know what the label is, but, according to the firm who are to run the right show, the wrong sort would be very inferior, being to a great extent built of fake. I shall be glad to see what the veroscope, or whatever the arrangement may be in this instance, says about the performance. It ought to hit off the doings of the boxers and give other particulars in if its use is to be justified, for, according to some reports, the men chiefly concerned went through a parlous lot for what they hoped might be a good deal in the way of show money. The lighting arrangements necessary to enable the instantaneous photographs to be taken reliably were responsible for tremendous heat, and both Jeffries and Sharkey suffered considerably through having what appears to have been an enormous grille of electric light right over their heads while they were hard at work. . . .

"This being thus suggests the question as to whether the exigencies of instantaneous photography and the value of royalties on the perfected pictures had much to do with letting things last as long as one of the boxers or both allowed them to rip. By all accounts it really was a tremendously hard battle—so hard, with big, heavy men hitting in earnest, that its going the whole twenty-five rounds is most remarkable. That it ought to have been stopped earlier is quite evident on the testimony of the person supposed to be the best judge of such matters—at least, so one must believe until evidence to the contrary is produced by the cinematograph or one of those remarkable illustrators. By the way, would it not be as well if, for a process such as a glove fight, divided by arrangement into set periods for action and armistice, the picture machine could be timed to run with the referee's or the official clock? One does not gain quite the correct impression from the views given so far—at least, one does not if the clock by appointment can be depended on. It seems sometimes as if the mutoscopic system went only from act to act—that is to say, action—and took no notice of the waits between. However, we shall see what we shall see when the time comes to bring the show over here."

### PHOTOGRAPHY AT ETON COLLEGE.

PROBABLY it is not generally known that the celebrated College at Eton has a photographic society which is ten years old. The Annual Exhibition was held last week, and the President, Mr. T. C. Porter, has been good enough to send us a copy of the catalogue. This is a well-produced book of thirty-eight pages, supplemented by twelve pages of half-tone reproductions of the exhibits, some of which, if we may judge by the process prints, are of a very high order of merit indeed. The photographs are described with great detail in the catalogue, and notes of the processes used are appended. Our readers, we are sure, will be interested in the following short account of the Eton College Photographic Society. It is extracted from the catalogue:—

The Society was founded (by the present President) in the year 1890, in which year it held its first public Exhibition in the room in the Queen's Schools, until recently used as a physical laboratory, and in the same room, and the adjoining lecture-room, was given the second Exhibition in 1892. The next year, owing to the increasing number of views exhibited, the Exhibition was held in the Upper School, and has so been held every year since that time, except in 1894, when the floods caused it to be postponed till the Lent Half, 1895, so that the present Exhibition is the tenth. Besides the photographic prints and enlargements exhibited in Upper School on occasions like the present, the members of the Society contribute lantern slides both for the Annual Lantern Evening, and from time to time read papers on photographic subjects, demonstrate photographic processes, and give accounts of their wanderings, illustrated by transparencies of their own making. They possess a very fair dark room, which is reserved exclusively for their use, and take in some photographic journal, which is kept in the School Library. Every member is bound to do a certain amount of work for the Society, and failure to comply with the rules in this respect is held equivalent to resignation; nor is any ex-member eligible for readmission. Entrance

to the Society is secured by the merit of photographic work, done solely by the candidate, and submitted by him for the President's inspection. This work must be free from certain photographic faults specified in the rules of the Society (an extract from these rules will be found appended to this account), and, provided the work is so far satisfactory, the President is bound to admit the candidate. The difficulty thus placed before those anxious to join undoubtedly tends to keep the number of members small, but this disadvantage is found to be more than compensated by the genuine and lasting interest felt in the subject by those who have taken sufficient pains to be successful; and, moreover, the fact that any one is a member of the Society is a sufficient guarantee that he has attained some proficiency in photographic methods.

As a rule, the Society numbers about a dozen present Etonians, with at present fifty old Etonian members, a few of whom generally send work to the Annual Exhibition, though, unlike present Etonian members, they are not bound to do so; they are, moreover, exempt from any subscription, which, in the case of all other members, comes to about fifteen shillings a year.

It is a rule of the Society that, at any public Exhibitions, each member may exhibit his own work only. When any of the work so exhibited seems to attract special attention, the exhibitor is invited to furnish a copy, which is forthwith mounted in a special book, and kept in the School Library for general inspection.

### EXTRACT FROM THE RULES OF THE E.C.P.S. RELATING TO ADMISSION TO THE SOCIETY.

14. The entrance work to qualify a candidate for admission to consist of not less than three finished prints on any ordinary printing-out paper—bromide, platinotype, &c.—at least quarter-plate size, and each candidate must declare the same to be entirely his own work.

15. That none be admitted on work done with a hand camera only, though two of the three views may be so taken.

16. That no piece of entrance work shall be accepted by the President unless free from the following faults:—

- (1) Spots both light and dark.
- (2) Lines due to scratches on negatives, hairs, dust, &c.
- (3) Bad focussing.
- (4) Bad colour.
- (5) Distortion—such as that which causes lines really perpendicular to appear slanting.
- (6) Great harshness in the print.
- (7) Red marks on the shadows in the print.
- (8) Fading of the print. With regard to this fault the candidate may be required to state the number of hours' washing the print has received.
- (9) Marks caused by the negative frilling or blistering.
- (10) The result of strong fog on the negative.
- (11) Great flatness in the print.
- (12) An ugly subject—if void of some distinct interest—historical or otherwise.
- (13) Pictures of a private nature—portraits, &c., may be rejected at the discretion of the President.
- (14) A mottled appearance of print.
- (15) Halation.

17. That, if the entrance work be approved, it be presented to an Entrance Work Book belonging to the Society, wherein it be duly mounted, and the particulars of the said work to be entered in a book specially kept for that purpose.

### A NEW SANDELL FILM.

MR. J. T. SANDELL, in his patent specification, gives the following description of a new rollable gelatine film which he has worked out: This film dispenses with all extraneous support for the sensitised emulsion, and is a film wholly of gelatine emulsion suitably hardened to render it self-supporting, and to adapt it for use as a continuous film in the roll-holder or cinematograph.

The film, Mr. Sandell states, is produced by coating a suitable surface by means of the well-known apparatus employed in the manufacture of dry plates, either with a single coating of emulsion of a thickness sufficient to afford the necessary tensile strength, or with two, three, or more superposed coatings of graduated degrees of sensitiveness, the coating (whether single or multiple) being afterwards stripped from the surface on which it is applied, and used without any adventitious support. The surface upon which the coating, or coatings, of emulsion is, or are, thus applied, is preferably that of a sheet or strip of glass, perfectly flat and highly polished; and, in order that the film may possess the hardness necessary to render it self-supporting, a hardening agent, such as an alum or formic aldehyde, is incorporated in sufficient quantity with the emulsion.

The proportion of the hardening agent will depend upon the initial state of hardness of the gelatine used in the composition of the emulsion, this hardness varying within somewhat wide limits in the case of different parcels of gelatine as supplied by manufacturers of that article. Generally speaking, however, about one and a half per cent. by weight of

chrome alum relatively to the weight of gelatine used in the emulsion will suffice.

The use of a hardening agent, as described, is of importance as tending to facilitate the manufacture of the films by accelerating the setting and drying of the emulsion, whether the films be formed of one or of several superposed coatings, it being, of course, necessary, in the latter case, to allow one coating to become thoroughly dry before a further coating is applied.

### AN AMERICAN PROFESSIONAL'S IDEAS ON RETOUCHING.

[Presidential Address to the Kansas Convention of Photographers.]

PROBABLY there is no subject pertaining to photography that has been discussed more than the subject of retouching, unless it would be the subject of developers, of which there seems to be no end. By retouching is meant to improve by new touches of the artist's hand to a work which has been considered finished before; therefore, to be a good retoucher, one should be a very clever artist, not necessarily a Raphael or a Borguereau, but he should be able to make a clever drawing of almost anything placed before him. He should possess a pair of good eyes and an overstock of patience, for success depends upon knowing how to be patient, how to unmake or remake, how to recommence and continue, without allowing the tide of anger or the flight of the imagination to arrest or divert the daily effort.

The necessary tools for the retoucher need not be many or expensive. A good stand, a few Faber or Hardmuth pencils (No. 2 to No. 6 H), a good retouching medium tempered with turpentine to furnish the proper tooth for these pencils, a bottle of Hance's ground-glass substitute, a bottle of alcohol, a few soft pine sticks, some clean rags, a good, sharp-pointed penknife, some India ink, some Chinese white, and some fine sand paper to sharpen pencils. Nearly every retoucher has a pet medium he likes best; but, for my part, I would prefer a mixture of Canada balsam of fir, resin, and chloroform, tempered with turpentine to suit your fancy. With this outfit you can meet all the requirements of the retoucher. If you have an air brush, so much the better, but it is not absolutely necessary.

In retouching a negative it is best to look it over carefully, and see if the contrast is too great or too weak from faulty development. If too strong, make a weak solution of hypo and red prussiate of potassium, and with a camel's-hair brush spread this solution all over that dense portion, which prints up like a snow bank, until the detail which was lost comes back again; but don't go to the extreme and take out all the life pluck. If the negative is too weak, it may be strengthened, as you all know, with a solution of mercury and bromide of potassium, or any portion of the negative may be built up by spreading this solution with a camel's-hair brush over that portion, until it has gained the required density, then darken the film with a solution of sulphite of soda, then rinse well with water. After the negative becomes dry it is a good plan to proof it, as you can tell better how to judge it for further treatment. After studying the proof carefully, and you find there is too much catch-light in the eyes, or warts and moles on the face, they may be reduced by a gentle scraping with the sharp blade of your penknife, or, better still, by taking one of your soft pine sticks and sharpening it to a fine point at one end and a rather blunt point at the other, then stretch a soft rag over the index finger of the left hand, moistened with alcohol, and hold it on the spot to be reduced, then take the pointed stick, also moistened in alcohol, in the right hand, and gently rub away the high light; then, with the alcohol rag, rub off the loosened gelatine until it looks clean and clear. There is no end to the amount of delicate reducing that can be done in this way.

Next in order is to fill up the hollows and build up the high lights with India ink. Take Higgins' liquid ink, reduced with soft water to the required shade, and mix in a touch of Antwerp blue to match the colour of the negative. With this build up the desired parts with faint and fairy-like touches, having ready in the left hand a piece of lintless blotting-paper to catch the accidental drop or blot of ink after each stroke of the brush. I use the best and highest-priced artist's flat red sable water-colour brushes I can find, capable of making a broad, smooth stroke, at the same time springing back to a point as fine as a needle. There is no end to the amount of ink work that can be done on a negative after a person gets into the practice of working on the gelatine surface, and the better the artist the more artistic the work, as a matter of course. After the negative has been brought forward thus far, it may be further prepared by rubbing on the retouching medium. I stretch a soft rag over the ball of the index finger, place it over the mouth of the bottle containing the medium until saturated, then rub it all over the negative as smooth and evenly as possible. Some only put the medium on the face and other parts to be pencilled; in this case the edge must be blended out, or else the negative varnished after the retouching is completed; if this precaution is not taken, the negative, being more translucent, will print a dark patchy place all around the head on the background of the finished print. In commencing to retouch a plate, I think it is best to start in the upper left hand corner and gradually work downward, and to the right over the entire face, taking out all freckles and blotches; afterwards build up the negative and soften down the wrinkles by a series of hatching, cross-hatching, and stippling, put on

in such a manner that the finished negative has a grain or stippled effect. In working out wrinkles and freckles, always work the pencil lightly in the transparent places, being careful not to touch the outside, or you will have extra trouble, and may have to wash all your pencil work off with turpentine and start over again. Another way of working is a sort of swaggering or dragging movement of the pencil in every conceivable direction, until a hollow cheek is filled, a shadow reduced, and a wrinkle softened, in fact the whole face is modelled and built up by this random wiggling movement of the pencil, until the face has a beautiful, even, soft, stippled effect, something like a fine miniature painting. I prefer this last style of retouching to the former, as the finished photos do not have the appearance of being retouched with a nail; I am speaking of the cabinets and smaller-sized photos; of course, in larger sizes you can be more broad in your handling, with good effect. Once in a while you will run on to a negative where the freckles are so deep and sharp that they seem to be out clean down through the film to the glass; they look like the operator had focussed his instrument to microscopic sharpness and blown bran in the face at the time of the exposure. Some customers have such bad freckles they would make a turkey egg ashamed of itself; in such cases the operator can help out matters wonderfully by turning the instrument a little out of focus, just enough to take off the wire edge and give full exposure. In retouching these tough cases, I prefer a 2 or 3H lead; if you do not get the most obstinate of these pits grubbed out, give them a rest until you model the face as beautiful as possible, not to lose the likeness; then go back to those deep freckles, blow your breath on them, and they will collect enough moisture to take a 2H. lead nicely. Just peek the pencil right in the freckle very cautiously lest you break through the film, in which case your only resort would be a fine p-pointed brush and India ink. After this breathing and stippling process, give the negative a coat of Hammer's retouching varnish and go after them again. By this time you will find them so completely flaxed out that you would have to take a microscope to find them. If you ever want to see what a good retoucher you are, just make a bromide print from one of your negatives, and I hardly think you will need a chain of argument to convince you. Once in a while you will have a negative that has a fine position, beautifully lighted, in fact everything heart could wish, with the exception of being flat—by not pushing the development long enough to give strength and pluck to the high lights of white drapery. In this case, after retouching the negative carefully, blow the back of it with Hance's ground-glass substitute, and carefully work on this with a fine red sable brush, moderately filled with a weak solution of Chinese white, and for broader effect use the air brush and Chinese white; for sharp, crisp, high lights use the white as thick as can be worked with a red sable, and be sure to place each touch of the brush exactly on the high light, which can easily be done when the negative is in the retouching frame. In printing from this negative it is a good plan to drive a small brad in one edge of the printing frame, and so place it to the sun that the brad casts no shadow in any direction. This will bring all your brush strokes and touches squarely between the high lights of your negative and the sun. If this precaution is not taken, your brush marks will cast a shadow to one side on account of the thickness of the glass and give a blotchy or patchy appearance to the prints. Another method is to use thin, fine linen paper on the back of the negative and work up the high lights with pencil and stump, but I prefer the ground glass and Chinese white, and then bind a clear glass on top of that in the manner of a lantern slide to protect it from getting marred and scratched. This may not be called legitimate photography, but, whatever faking is resorted to on the negative is legitimate if the effect of the finished picture is heightened thereby, and I hardly think there is any one who would not forgive the sin after viewing the beautiful result thus obtained.

Now, as we have gone over the mechanical operation, allow me to caution you not to retouch too much, for it is just as bad, if not worse, to overdo than not to do at all. Be careful not to give the face a puffed or blown-up expression, especially to people with round, full faces. If you have a hatchet-faced subject, you will never hear them complain if you puff them up considerably, and it is just as necessary to please in selling a dozen photos as it is in selling a pair of shoes. It is a matter of business. However, in working the negative of a celebrated person in any sphere of life, you should first get a good likeness and a rich chemical effect, then retouch as little as possible, only to modify their glaring defects, for you are then handling public property, and the public demands facts and not your ideals on subjects.

We will now examine the different parts of the face that require special attention. This drawing of the skull will present to you a view of the main foundation of all human expression. Upon this foundation is fastened all the muscles that play such an important part in telling whether we are glad or whether we are mad, joyful or sorrowful, filled with pleasure or filled with pain. It is not necessary for the retoucher to know all the muscles like a doctor, yet it will not be any disadvantage to him if he will study a few that play such important parts in the expression, such as the occipito frontals, the orbicularis palpebrarum and the orbicularis oris. Very often a customer remarks, "Ye, I like the proof very much, but it has such a cross look, such a sad look, or just as though I had a tooth pulled." The retoucher, by understanding the action of these muscles, can change the expression from a sad look to one of

pleasure, or one looking too pleasant can be reduced to soberness. Probably the orbicular muscle of the mouth, and the corrigator supercilli concerns the retoucher most, but it is impossible for the average man to work around the orbicular muscles of the eye without losing the likeness, until he becomes an expert. Even then, he has to work extremely cautious, consequently it is best to work around the eyes as little as possible. Sometimes a subject naturally has a cross look, almost verging to madness, especially in the adult, as the cares of life have stamped their ineradicable marks upon the face; they look like a mad cat; the eyebrows are knit, and the mouth runs down at the corners. In such cases the deep wrinkles between the eyes should be softened, the shadows at the corners of the mouth turned upward, and thick lips slightly reduced. But, of all the jobs that make a retoucher curse, it is a lady with low-neck dress, that has a neck as skinny and bony as a mud turtle, and expects you to retouch it as plump as a butter ball. This drawing will give you some idea of such a task; but don't get discouraged, don't falter, don't wish that you were dead. Keep the shadows of your anger and imperfections behind you. Put as much thought into the picture as possible, and remember that every real thought on every real subject knocks the wind out of somebody or other. As to the retouching of landscapes, there is as much or more latitude than in portraiture, but the best plan is to make nature do the work as far as possible. Make your negatives early in the morning, when the chickens begin to hunt their food, when the air is full of perfume, and the bee is gathering sweet from the flowers, or in the evening, when the weary farmer plods on his homeward way, when the lengthening shadows cross the golden fields and the blushing sun lies far in the west.

R. B. HANSFORD.

#### SCREENS FOR ORTHOCHROMATIC PHOTOGRAPHY.

MR. R. W. ARTLETT, according to his patent specification, proposes to employ two discs of glass (figs. 1 and 2), which preferably have plane surfaces, but which may ground to a slight curvature. Each of these is coated on one side with a film of gelatine, collodion, or other suitable material, and each film is then dyed, the one (fig. 1) a strong bright yellow, and the other (fig. 2) a clear strong red. The yellow-dyed film

permits the red, yellow, and green rays to pass, and intercepts the whole, or nearly the whole, of the blue rays, whilst the red-dyed film operates to intercept the violet, indigo, blue, and green rays. In the centre of the yellow film there is a small circular vacant space, *a*, and in the centre of the red film there is a comparatively large circular vacant space, *b*. The two discs are now cemented together, film to film (fig. 3), with Canada balsam or other cement having a refractive power corresponding as nearly as may be with that of the gelatine or collodion film.

Mr. Artlett states that a coloured screen prepared in the manner above described transmits a small quantity of the very energetic blue and violet rays (along with the other rays constituting white light) through the central space left vacant in both films, a large quantity of the green rays (with red and yellow) through the yellow annular space which intervenes between the central clear space, *a*, and the red film, and a much larger quantity of the comparatively inactive orange and red rays through the outer or red-cum-yellow portion of the compound screen.

By adjusting the proportions between the central or clear portion, the outer or red-cum-yellow portion, and the intervening yellow portions of the screen, the quality of the light admitted may be regulated so as to obtain the most perfect results, and, although it is desirable to have a small central vacant space in the yellow-dyed film, it may sometimes happen that the circumstances will admit of the use of the film intact.

The screen is placed in the lens in a position as near as may be to the diaphragm.

#### THE REDHILL AND DISTRICT CAMERA CLUB'S CONVERSAZIONE.

THIS rising Club, which owes its inception to an influential body of very ardent photographers, celebrated its first anniversary at the Market Hall, Redhill, on Friday, November 24, by a most enjoyable *Conversazione*. The company that attended was a select one, and was notable for a goodly sprinkling of ladies, who have more or less become initiated into the art of photography. The reception took place in the small assembly room, where the *Conversazione* was held. Among those who were specially invited were the Mayor of Reigate (Mr. F. E. Barnes, J.P., C.C.) and the Mayoress, Mr. William Conolly (Chairman of the Redhill Technical Institute) and Mrs. Conolly, Mr. and Mrs. P. N. Hasluck, Mr. W. H. Rogers (Secretary of the Camera Club, Croydon), and Mr. Pierce (Secretary of the Photographic Section of the Natural History Society, Croydon), and many other ladies and gentlemen.

A local contemporary says that the Exhibition, though not an extensive one, was, in point of merit, one of the best, if not the very best, of the collections of high-class photographs which have been seen in this part of Surrey. As this is the best Exhibition which the Club has organized, still more meritorious displays may be expected in the future. In its first year of existence the Club could hardly be expected to give prizes; certificates therefore were awarded instead. The winners of the certificates were Dr. Dutton, Mrs. Arthur Thompson, Mr. T. Percivale Padwick, Miss K. D. Flemming, Mr. J. O. Grant, and Miss Mabel Pelly. The somewhat difficult task of judging the exhibits was performed by Mr. Ralph W. Robinson, the well-known photographic artist.

The Exhibition was chiefly remarkable for the simple charms of the subjects selected and the rich shading of some of the land and seascapes. The cloud and sunshine effects, too, were highly artistic. A number of non-competitive pictures were sandwiched in with the lesser lights. One of these was an enlarged negative of a fire which took place at Messrs. T. S. Marriage & Co.'s, at Reigate. Mr. Ralph Robinson, as Vice-President of the Club, exhibited amongst other pictures a beautiful photo of the head of a child (draped). *Bringing Home the May*, 1863 (medal), and *Carolling* (medal), were among a rich collection lent by Mr. H. P. Robinson, Tunbridge Wells. A masterpiece of detail and skill, as well as an example of perfect finish, was a panorama photo lent by Mr. Henry Speyer (Alpine and Camera Clubs). This was a combination photograph of the vast panorama that meets the eye from the Gross Viescherhorn, a mountain, 13,281 ft. high, in the Oberland Alps.

The latter part of the evening was taken up by an interesting lantern exhibition by Mr. Wm. Brooks. The exhibition consisted of four series of photographic slides, most of which were taken by members of the Club. The first series included a number of "up the river" illustrations, taken by Mr. Arthur Dunning, who gave a few explanatory words to each slide. The other two series represented the work of Messrs. J. O. Grant and F. Martin Duncan. The last series was the work of the operator of the lantern, Mr. Brooks, who showed a great number of interesting pictures which he had taken during his rambles in various parts of England, principally in Devon and Cornwall. A few photos of the wrecks of the *Mohegan* and the *City of Paris* on the Manacles, were also included.

#### CROYDON MICROSCOPICAL AND NATURAL HISTORY CLUB'S ANNUAL SOIREE.

THE Annual *soirée* of the Croydon Microscopical and Natural History Club was held on Wednesday, November 29, at the Public Hall, Croydon. A local contemporary states that the large hall was devoted to exhibits of microscopes and microscopical objects, photographic and other scientific apparatus, and zoological and ornithological specimens. In the small hall and corridor were photographs and transparencies, while the botanical, entomological, ethnological, and art collections were on view. The Röntgen ray apparatus occupied a room to itself, and the Old School of Art room was devoted to demonstrations with the lantern.

The exhibitions of lantern slides were excellent, Mr. W. Brooks, of

Reigate, showing a beautiful series of photographs, among them being a number of views of the *Paris* on the Manacles, and of the *Mohegan*, which was also wrecked at the same place. A number of slides by members of the Club were also shown.

The demonstration given by Mr. W. Saville-Kent, F.L.S., F.Z.S., of trichromatic photography, was full of instruction. Mr. Kent has devoted considerable attention within the past year to the subject of trichromatic or three-colour photography, as applied to the correct colour registration of zoological and botanical subjects. With the aid of the lantern, he exhibited on the screen, as also in special frames in the public hall, lantern slides and larger transparencies of a series of examples upon which he had most successfully experimented.

Among the slides displayed, that of a peacock's feather, in which the characteristic tints were reproduced with marked fidelity, was particularly noteworthy as a successful demonstration of the capabilities of the system adopted. Orchids and various strikingly coloured flowers, gold and silver carp and other fishes, lizards, and birds in many varieties were included in the series submitted.

Among the fishes, an example of a John Dory in the act of engulphing a smaller fish in its peculiarly distensible jaws, presented a most realistic aspect. This, with other fish subjects, had been taken by Mr. Saville-Kent during the past summer at the Plymouth Marine Zoological Station.

In the bird series, a little group of Australian gouldian finches, *Poephila Gouldii* and *Mirabilis*, remarkable for the almost parrot-like brilliancy of their plumage, attracted much attention. In addition to the coloured photograph of a little group of these birds that had been artistically set up for the exhibitor by Mr. Charles Thorpe, Mr. Saville-Kent submitted a replica that he had prepared as a lantern transparency of a water-colour drawing of the same birds that had been executed for him by the bird artist, Mr. J. S. Kentemans, from living examples that were recently in his possession, and which drawing was reproduced in his last work, *The Naturalist in Australia*. This example was specially referred to as demonstrating the applicability of the process adopted for the reproduction in a like manner of coloured illustrations from other more rare and costly natural history or artistic publications.

#### NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE Annual Exhibition of the work of the members of this Society was held at Jubilee House, Hornsey-road, N., on the 4th, 5th, and 6th inst.

In reviewing photographic societies' exhibitions it has been our duty, more frequently than not, to criticise adversely the system of classification adopted. We have been assured by society officials that a division into classes is necessary for the success of an exhibition; in effect, that, unless there is some chance of an inferior photograph gaining an award, those members who know they cannot produce pictures equal to the standard of the leading members of the society will not exhibit. We have often endeavoured to show the fallacy of this method of reasoning, and have always had sufficient faith in the *esprit-de-corps* of the members of our leading societies to believe that they would work quite as enthusiastically to make their exhibition a success without the adventitious stimulus of medals or awards. In the North Middlesex Society's Exhibition we have a notable proof of our contention to a certain point. It is true that there are awards, but only in a very limited sense can they be compared with the silver and bronze medals, &c., that are usually offered for competition. There are no classes, and the function of the Judges is to select from the collective exhibits those among them that they consider worthy of particular distinction. The award takes the form of a certificate. The system is, in fact, that of the Royal Photographic Society's Exhibition. That the North Middlesex Society is justified in its method is proved by the fact that, for some years at least, no local society has been able to make annually a better show, entirely the work of its own members, than this Society does, and very few societies indeed do as well.

We are pleased to report that this year's Exhibition was quite up to the usual standard. To say that it was not greatly in advance of last year's show does not imply any reproach on the Society, for the work had already reached the standard upon which improvement must necessarily be slow. There was, however, a notable absence of work which demonstrated the usual faults of the beginner. We heartily join with the Judges, Messrs. Jas. A. Sinclair, F.R.P.S., and F. C. Tilney, in the regret expressed in their report, "that outdoor figure studies have not made more claim upon the attention of the members," and we commend this to the attention of members.

There is very little doubt that, although we keep our place as landscape photographers, we are becoming woefully behind our foreign brethren in figure studies. In lantern slides the Society has done remarkably well. Lantern-slide work is certainly not as popular as it was, and it is a notable feature of this Society that the exhibits of lantern slides have both increased in number and very greatly improved in quality.

The abstract of the printing processes employed, as given in the catalogue may be interesting: Bromide, 60; carbon, 44; gum-bichromate, 7; platinum, 47; gelatino and collodio-chloride, 8. The number of

frames was about twenty less than last year; but, as the average size was larger, the walls were as well covered. The general arrangement of the gallery was as usual, and we need hardly say the details of the Exhibition were carried out admirably.

The Judges comment upon the fact that some of the finest work is included in that marked "not for competition." The members whose work was so marked were Mr. J. C. S. Mummery (President of the Society), and Mr. H. W. Bennett, and among their exhibits were several that were shown and duly admired at the last Pall Mall Exhibition. After these Mr. R. R. Rawkins comes off with the most honours, as will be seen by the list of awards, and they are honours which were well deserved. With another year's practice he ought to come well to the front. In addition to those exhibitors whose works have been distinguished by the Judges, there were admirable pictures shown by Messrs. R. Child Bayley, E. R. Mattocks, W. Taylor, and J. W. Marchant; and lantern slides by Messrs. F. A. Bishop, J. M. Ainsley, A. T. Crane. A set of lantern slides of astronomical subjects by Mr. S. J. Clay, marked "not for competition," deserved special praise.

#### THE AWARDS.

Pictures.—*Ancestral Trees*, Mr. A. G. Lawson; *Memories*, Mr. A. H. Lisett; *Land of the Mountain and Flood*, Mr. Charles Beadle; *A Fair Artist*, Mr. H. Stuart; *A Watch Boat*, Mr. R. R. Rawkins; *In the Smithy*, Mr. J. J. Armitage; *Winding the Bobbins*, Mr. G. A. Barton; *The Chancel, Hereford Cathedral*, Mr. D. H. W. Broad.

Lantern Slides.—Messrs. H. W. Mattocks and R. R. Rawkins.

#### COMMENDED.

Pictures.—*A Canal Lock*, Mr. R. R. Rawkins; *Christ Church College Cambridge*, Mr. R. R. Rawkins; *Sunshine*, Mr. S. Herbert Fry.

## Our Editorial Table.

#### THE GOERZ PHOTO-STEREO BINOCULAR.

Manufactured by C. P. Goerz, 3 & 4 Holborn-circus, E.C.

This ingenious little instrument fulfils the three functions of opera glass, field glass, and photographic camera, monocular or binocular. The first

of the two illustrations shows it closed up, *m* indicating revolving diaphragms, and *q* the lug for attaching the camera to a stand. The

second illustration shows the back of the instrument, carrying the binocular lenses, let down, and giving a view of the ground glass, *x*, and

the plate-holder, c. K, k pull out the sliding frames, B, B, in which the plate-holders are placed; R, n carry the binocular eyelenses and the camera objectives. A shutter is actuated at c. The plate-holders are of thin sheet metal and take plates 4½ x 5 cm. By one or two simple adjustments of pegs situated near to c, but not visible in the block, the camera is adapted for either monocular or binocular work. The image may be focused and very rapid exposures given. When K is drawn out the shutter covering the plate is removed, and after exposure K is pushed back and the plate-holder easily removed. The movements for converting the instrument from a camera into an opera or field glass are exceedingly simple—indeed, “in changing the instrument from binocular to camera or *vice versa* no unscrewing or separating of the parts is necessary.” The Photo-stereo Binocular should find many admirers.

#### SIENNATYPE PAPER.

Otto Scholzlg, 131, Binsfield-road, Clapham-road, London, S.W.

THIS paper yields prints of a peculiarly pleasing shade of reddish-brown, and we have no doubt that many photographers will welcome and appreciate it. We append the instructions for use:—Print out to the depth of an albumen or P.O.P. print. Soak the prints three minutes in a one per cent. solution of carbonate of potash or carbonate of soda, then wash in two changes of water. Tone and fix ten for twenty minutes in the following combined toning and fixing bath:—

Water ..... 16 ounces.  
Hypo ..... 3 ”

Dissolve and add—

Sulphocyanide of ammonium ..... 3 drachms.

When dissolved, add—

Gold solution (one grain to the drachm) ..... 7 drachms.

The bath is ready as soon as mixed, and will be sufficient to tone seven full sheets of paper, when it should be replaced by a new bath. Wash thirty minutes in many changes of water.

A great variety of tones can be produced with Siennatype paper if, after the potash bath and washing, the prints are toned in any of the baths recommended for albumen paper, and subsequently fixed in hypo.

#### THE “ROYAL” PLATES.

Manufactured by Cadett & Neall, Ashtead, Surrey.

UNDER the happily chosen name of the “Royal,” Messrs. Cadett & Neall are placing on the market a new brand of plates. With the developing formulae specially mentioned in the instructions, the rapidity of the plates = 100 H. & D. Qualitatively speaking, the negatives yielded by the “Royal” plates are all that can be desired, a clean, fine-grained deposit with sufficient opacity in the shadows being their characteristics. Moreover, their degree of rapidity is such that they present the maximum of ease and convenience in manipulation. A special feature of the “Royal” plates is that the quarters, as well as some of the larger sizes, are specially packed, so that repacking is simplified. Thin glass is chosen, and two plates are placed face to face in contact, the films not being cut through. Before filling the slides or sheaths, the slightest pressure severs the films. After exposure they are repacked, film side to film side, and secured in the tissue wrappings by means of rubber bands, which are placed round the original packages. Many travelling amateurs will, we are sure, appreciate these little conveniences so thoughtfully provided by Messrs. Cadett & Neall, who consider the “Royal” the best plate they have yet marketed. As the Ashtead house has always borne a very high reputation for the quality of their plates, the “Royal” should add another to the many successes they have achieved in this branch of photographic manufacture.

#### GRAVURA OPALS.

Manufactured by the Paget Prize Plate Company, Watford.

THE fact that they may be manipulated in weak actinic light, coupled with their adaptability for giving a range of colour, should make Gravura opals exceedingly popular. We have often wondered that photographic printing on opals was not taken up to a greater extent by amateurs than we find to be the case. They have only to realise how easily Gravura opals yield good results, and we imagine that many will take up this form of printing for a purpose to which it is so well adapted, namely, domestic decoration. Besides full instructions for making Gravura opals and lantern plates, each package of plates contains pieces of paper coated with the same emulsion as the opals for trial exposures—a great convenience.

#### THE “LUVEX” LANTERN.

R. & J. Beck (Limited), 68, Cornhill, E.C.

THIS lantern has been specially designed for home use. As illustrated, it is arranged for ordinary house gas in connexion with the Welsbach

burner; the only operation necessary is the joining up of the tube, c, to any handy gas supply. The polished mahogany box into which the lantern is packed away measures only 12 inches by 8 inches by 7 inches over all, and in it there is also room for the slide-carrier, cowl, and incandescent attachment. The lantern, when extended, measures 2 feet by 1 foot 6 inches by 7 inches. The box which contains the lantern has a hinged lid, which enables the instrument to be considerably tilted. To put the lantern away, the objective, D, is unscrewed and rescrewed in

position on its flange inside the mahogany chamber, r, which is then pushed up as far as possible towards the condenser. The slide-carrier, x, having been removed, the square Russian iron body, B, is then slid upwards off its brass support, reversed, and pushed down on the same support, but in a reversed direction, over the condenser, mount, and mahogany chamber, r. When this operation is completed, and the cowl, A, taken off, the lantern measures only 7 inches by 6½ inches by 5 inches. The lantern is then unscrewed from the tilting lid and slipped

into the box, when there will be found to be room for the slide-carrier. Welsbach attachment, gas bracket, iron cowl, &c. The “Luvex” tracing-paper screen is made of paper, and is mounted on a spring roller, so that it is always kept in good condition. When wanted for use, it is simply pulled out by the top lath, and, being fully extended, the side laths are fixed and the feet spread out. When closed, it is in the shape of a long compact box. The screen is 3 feet 6 inches square, a convenient drawing-room size.

## WIMBORNE AND CHRISTCHURCH.

By the REV. THOMAS PERKINS, M.A.

134 pp. With about sixty illustrations. Price 1s. 6d.

London: George Bell &amp; Sons, York-street, Covent-garden, W.C.

MR. PERKINS, whose name is, of course, familiar to our readers as a frequent and appreciated writer on photography, gives in this little book a short history of the foundation and a description of the well-known Minster at Wimborne and the Priory at Christchurch. The book is full of the most interesting details concerning the two churches, and the excellent reproductions of Mr. Perkins' carefully taken photographs very greatly add to its value. To ourselves, who have often visited the great Priory at Christchurch, the volume is especially useful, but we imagine that the book will appeal to a very wide circle of readers interested in the history of our cathedrals and larger churches.

## THE STANDARD DICTIONARY.

AMERICAN printing and publishing productions are always well to the front, and Messrs. Funk & Wagnall's Standard Dictionary, which is being issued by arrangement with the *Illustrated London News*, and can be had on the instalment plan, supplies our bookshelves with another very excellent work of reference.

The dictionary claims to contain nearly 80,000 more terms than any other work of a similar character, and its illustrations, particularly its coloured plates, are superb.

The patent index, which enables the reader to put his finger on the reference letter without having to turn over page after page, is very useful, and altogether the work, which is in two volumes, is replete with every modern improvement.

MESSRS. L. GAUMONT & Co., of 25, Cecil-court, London, W.C., have issued a new catalogue of the Lumière & Elgé cinematograph films, the drawing-room chromo projector, the Lumière projector, &c.

## OUR RARER BRITISH BREEDING BIRDS: THEIR NESTS, EGGS, AND SUMMER HAUNTS.

By RICHARD KEARTON, F.Z.S. With seventy illustrations from photographs by C. Kerton. 150 pp. Price 7s. 6d. London: Cassell & Co., Limited.

THE MESSRS. KERTON have again placed lovers of natural history under an obligation to them by this superb book. It appeals in an especial manner to bird lovers by reason of the rarity of many of the subjects that are described and photographed; but it is also assured of general welcome, for it is the record of most painstaking endeavours to set before us evidence of the richness of ornithological treasures with which these islands abound. In a publisher's note we read that whilst engaged upon the preparation of the book, the brothers Kerton travelled about ten thousand miles. They have culled their materials from different parts of England, Scotland, Ireland, Wales, and the surrounding islands, and the book includes pictures of the nests, eggs, or breeding haunts of nearly sixty species not pictorially represented in their previous work on *British Birds' Nests*. These include such rare specimens as the marsh, montagu, and hen harriers, kite, whimbrel, siskin, crossbill, chough, Kentish plover, osprey, and red-necked phalarope.

In his preface the author enters a strong plea for the better protection of wild birds and their eggs than is afforded by the Acts dealing with the matter, and in this he will secure the widest sympathy. The descriptive matter is terse and lucid, and we do not know which to praise the most highly, the splendid photographs or the really fine half-tone reproductions of them. We have not seen better of either. Altogether it is a remarkably beautiful book, and it well merits a place in the library of every lover of natural history and bird life.

## News and Notes.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On December 14 there will be a Lantern Night, when Mr. Thomas E. Freshwater will show some recent photo-micrographs. Visitors are always welcome.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, December 12, at 86, Russell-square, at eight p.m. Mr. Thomas Bolas will read two papers, "Notes on the Use of the Dallmeyer Focometer," and "The Origination of Printing Types by Photographic Methods."

THE second volume of Dr. Isaac Roberts' *Photographs of Stars, Star Clusters, and Nebulae* is about to be issued from the publishing office of Knowledge. It will contain seventy-two photographs reproduced by the collotype process, in addition to many pages of text. Only a limited number of copies of the work will be available for the public.

THORNTON HEATH POLYTECHNIC PHOTOGRAPHIC SOCIETY.—A lecture, entitled "The Elementary Principles and Practical Uses of the Photographic Lens," illustrated with limelight diagrams and mechanical slides, will be delivered by Mr. F. O. Bynoe in the lecture-room of the Thornton Heath Polytechnic on Tuesday, December 12, at eight o'clock precisely. The chair will be taken by Dr. C. Owen Fowler.

Re WILLIAM HENRY FREDERICK BOWMAN, lately carrying on business as a photographer, Heaton-street, Gainsborough. The public examination of the above-named debtor took place at the last sitting of the Lincoln Bankruptcy Court, before Mr. Registrar Stephens. The statement of affairs filed by the debtor showed liabilities amounting to 141l. 12s., and assets estimated to produce 14l. 15s. The debtor attributed his failure to putting an instalment of electric light in the Albert Theatre and never getting paid for it. The order was given him by Mr. Kirk, but when he tried to recover the money the defence was that he had put the instalment in as an advertisement. Altogether the cost alone was 900l., and he spent an additional 40l. in law expenses. Subsequently the fittings were removed, but the cost of taking them out was more than they realised. Mr. Tweed, for certain creditors, questioned the debtor concerning the alleged sale of his photographic business, and the examination was eventually adjourned.

TO "TELE-PHOTOGRAPH" THE BOERS.—The *Daily Mail* says: "For the first time in history, the tele-photographer is about to play his part—it may be a very important part—in warfare. Second-Corporal Ford, of the Royal Engineers, Chatham, has been detailed as tele-photographer to the Army in South Africa, and has sailed from Southampton with his cycle and apparatus. Corporal Ford's camera, which is fitted with tele-photo lenses, will take a clear photograph of a man, or battery, or entrenchments, at any distance up to two miles, so that, beyond the range of the enemy's rifles, Corporal Ford will be able to get photographs of their positions, which should prove of great value. As military tele-photographic scout he ought to be able to render very useful service to the British Army. The special apparatus was devised by Lieutenant Foulke, R.E., and made by the London Stereoscopic Company. It is fixed on to Corporal Ford's bicycle in such small compass as to be hardly noticeable, and the whole thing—bicycle and apparatus—is painted the familiar khaki colour."

THE Secretary of the British Mutoscope and Biograph Company last week wrote to a daily contemporary in these terms: "In your issue of this day, under the head of 'A Mutoscope Exhibition: Alleged Indecent Pictures,' a paragraph appears in which, having referred to the popularity of the mutoscope exhibitions, you give an account of the proceedings taken by the police against the occupier of the premises, No. 69, High Holborn, for exhibiting for the purpose of gain indecent pictures at that address. Will you allow me to say that the term 'Mutoscope' is not a generic word, but a registered trade mark, the property of this Company, and is applicable only to moving pictures. The pictures which were seized were not of this class, being ordinary stereoscopic coloured photographs; they have no connexion with this Company or any one having relation with it, and were exhibited in machines called 'kalloscopes.' We are informed that the word 'Mutoscope' was not mentioned throughout the proceedings. We welcome this action on the part of the authorities."

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

## ROYAL PHOTOGRAPHIC SOCIETY.

DECEMBER 5.—Lantern Evening.—Mr. J. J. Vezev in the chair.

## LINCOLN CATHEDRAL.

Mr. FREDERICK H. EVANS delivered a lecture on "Lincoln Cathedral," illustrated by about one hundred and thirty slides from his own negatives, and Mr. Evans's photographs of the English cathedral church are so well known that it is hardly necessary to say that the ladies and gentlemen who disregarded the weather and found their way to Russell-square on Tuesday evening were amply repaid for their trouble. In the course of his brief introductory remarks, the lecturer said he thought that in architecture photography found its most useful and least hampered exhibition; architectural subjects imposed less restrictions than landscape or figure work, their form was stable and motionless, the gradation and translation of their colour was not difficult of rendition; and, although they called for accurate drawing, good composition, and true effects of light and shade, photography was capable, in the hands of an artist, of adequately dealing with all these elements and of yielding truer and more complete results than could be expected from the average painter or draughtsman. To do such work, and to do it properly, called for incessant study, observation, and training of the eye and the memory, and for an apprenticeship as exacting as that of the draughtsman or painter. To do justice to a building it was necessary to devote great attention to the niceties of composition and of light and shade, and even in so apparently simple a matter as taking the detail of a carved capital there was a wrong position and a right one for the camera, and the direction of the light must also be correct if the details were not to be confused or ill-drawn or improperly massed. To isolate and study and appreciate the more recondite beauties of a cathedral, one must visit it many times and see the building at all hours and in all qualities of light, the brilliant sun and the quiet grey day each having its own value and effect. Each picture exists at its best at but one part of the day, perhaps at but one half-hour of the day, and every composition that one thinks worthy of recording should be seen and studied at all hours to find its truest lighting. Turning to the subject of the lecture, Mr. Evans first showed some general views of the cathedral from various parts of the city, those from the High-street and Steephill being particularly effective; and he then proceeded to conduct his hearers over the whole of the noble minster, giving historical, architectural, and archaeological particulars of every detail of the structure. As an instance of the thoroughness of his treatment of the subject, it may be said that the west front alone was illustrated by no less than twenty-one slides, including representations of Norman work behind the Early English arcading, the Saxon sculptures depicting scenes from Old Testament history, the eleven kings over the doorway, &c. Then some very fine photographs of the south-west and central towers were shown, these being followed by interior views—the nave, font, aisles, organ-screen, north and south choir aisles, the beautiful angel choir (ten or more views), the choir, transepts, presbytery, and chapter-house. The extraordinary grotesque sculptures near the north-east transept afforded what the lecturer called "comic relief" both to the lecture and the cathedral. The last picture was an exceedingly pretty view from the vicar's court, taken in early spring, the delicate branches of the trees acting as a lovely foil to the matchless towers seen through them.

Mr. JOHN LIGHTON, F.S.A., at the close of the lecture, exhibited two old prints from waxed-paper negatives, and expressed his astonishment at the marvellous progress of photography since the time when those negatives were taken, referring to the advances which had been made in photo-mechanical work, which he described as "perfectly stunning and astounding." He said that the *Graphic* had now entirely ceased to employ engravers except for "finishing" work.

## COMING EVENTS.

December 12, Ordinary Meeting, "Notes on the Use of Dallmeyer's Focometer" and "The Origination of Printing Types by Photographic Methods," both by Mr. T. Bolas. December 19, Photo-mechanical Meeting, "Negatives for Three-colour Work," by Captain W. de W. Abney, F.R.S. January 2, 1900, Lantern Evening, "Round about the Matterhorn and the Aletsch Glacier," by Mr. H. Speyer.

## LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 30.—Mr. R. P. Drage in the chair.

Mr. H. VIVIAN HYDE gave a lantern show, entitled

## LOWESTOFT AND NEIGHBOURHOOD.

The character of the country was well portrayed by a large number of typical pictures, taken mostly with the hand camera, and naturally a good proportion was connected with the staple industry of the town. The quays, the departing and approaching smacks, the harbour loungers and market people offer splendid opportunities to the observant photographer, and it was hereabouts that Mr. Hyde perhaps succeeded best. Leaving Lowestoft, the audience was conducted inland to the "broads" district, Oulton, Beccles, &c., on to Norwich. The display was concluded with a few slides taken in Surrey in the vicinity of Dorking and Guildford. A vote of thanks was passed to Mr. Hyde.

## PHOTOGRAPHIC CLUB.

NOVEMBER 29.—Mr. F. A. Bridge in the chair.

There was a large gathering to hear Mr. THOMAS FALL's chat on

## WILD AND DOMESTIC ANIMALS, AND HOW I PHOTOGRAPHED THEM.

drawn together by the knowledge of his successful treatment of a most-trying and difficult subject. The real secret seems to be to cultivate an unflinching patience, and to study sympathetically the many peculiarities of the animals one has to deal with. It has been a long study with Mr. Fall, as his results conclusively show, and the quality of the pictures and his lucid description of the habits of the subjects well deserved the hearty vote of thanks which was accorded to him.

Richmond Camera Club.—November 27.—Mr. J. D. GIBSON (one of the Hon. Secretaries of the Club) gave a demonstration on

## COPYING.

He showed how, by means of strips of magnesium ribbon burned on each side of the object to be copied, care being taken to shield the light so that none of the direct rays could reach the lens of the copying camera, it was easy to obtain a negative of a portrait, landscape, &c., photographic or otherwise. Of course, in copying a coloured picture or other object, it was necessary to use orthochromatic plates and a screen, but for copying photographs or engravings ordinary plates answer perfectly. The object of burning the ribbon on both sides of the object was to obtain evenness of illumination, and to prevent the grain of the paper or other material showing. Mr. Gibson referred to the ease with which the exposure could be regulated, and the certainty of achieving uniform results when once the correct amount of ribbon to be burned and the stop to be used in the lens had been ascertained. He then made two copies of a cabinet photograph on quarter-plates, one with eight inches of ribbon, and the other, at the suggestion of Mr. Cembrano, with four. The former result was thought to be the better of the two negatives, both of which were, however, very satisfactory.

South London Photographic Society.—Mr. W. H. DAWSON, the President of the Woolwich Society and also a member of the South London Photographic Society, on Monday, December 4, gave his brother members a lecture entitled

## A BRIEF HISTORY OF BRITISH ARCHITECTURE,

exhibiting most of the various types by pictures projected by the lantern. The lecturer had taken very great pains to procure examples of the different styles and their gradual transformation from the best-known subjects in England, and conclusively proved to his audience that there is more in architectural photography than mere records or picture-making.

Eccles Photographic Society.—On Monday, November 27, a very representative meeting of photographers was held in the rooms of the Co-operative Society, Eccles, when it was unanimously decided to commence a photographic society. A goodly number at once joined, and a strong working Committee was appointed, with Mr. J. Morris, Ph.D., F.C.S., Boardman-street, Eccles, as Hon. Secretary, and Mr. E. Johnson, Da Vinci, Ellesmere Park, Eccles, as President. The first meeting is to be held early in the new year, when it is proposed to have a social meeting, at which apparatus, negatives, prints, lantern slides, &c., can be inspected by the members.

Leeds Camera Club.—November 29, Mr. R. Bourke (Vice-President) in the chair.

## THE WELLINGTON &amp; WARD NEGATIVE FILMS

were the subject of a lecture given by Mr. HARRY WADE, of Manchester. The use of films, said the lecturer, appealed to the amateur photographer on account of their lightness, for it became a serious matter to carry with him many plates when on a walking or cycling tour. Hitherto many difficulties had to be encountered, but he thought he would be able to show them that with this film they had been successfully overcome. It was a film of gelatine, coated as an ordinary plate on a support of white paper, and was placed in the slide in the ordinary way, having a piece of thick cardboard behind it to hold it in position. It was of sufficient speed to be used for rapid exposure; and the emulsion admitted of almost any degree of density being obtained in the subsequent development. Being in optical contact with its support, halation was altogether absent, and so one of the most messy but still necessary operations with the ordinary plates was avoided. In the manipulation there was not the difficulty usually met with; there was no curling, the films were soaked until limp, and developed in the usual way, and, whilst the makers advocated the pyro-ammonia developer, yet pyro soda, or any of the later developers in use, could be used with satisfactory results. The paper support was sufficiently transparent to enable density to be judged by transmitted light, although, of course, no image was visible at the back. When developed, they were well washed and immersed in a weak alum bath for ten or fifteen minutes, washed again, and fixed in the usual hypo bath, and finally well washed for about an hour, then squeezed on to a waxed ferrotype plate. When quite dry they easily came off. The film had now to be removed from its paper support, which was done by cutting through the film down one edge, taking care not to cut the support, and, by inserting the point of a penknife and running it round the edge, the film could be then easily withdrawn by the fingers. The back of the film, being a matted surface, readily lent itself to any retouching or work on the same without any medium being applied, and in the printing could be used from either side, a most obvious advantage in the case of carbon work. The films were put up in the sizes of ordinary plates, and for hand-camera work were spooled to fit the roll-holders in present use. The negative film is flexible, of sufficient body to stand rough handling, and could be protected against silver staining by being immersed in any suitable varnish. A large series of prints and negatives were passed round for the inspection of the members present, showing that, for fineness of grain, delicacy of gradation, they gave everything that the makers claimed for them.

Liverpool Amateur Photographic Association.—November 30.—Mr. Paul Lange presided, and there was a large attendance of members present. Four new members were elected, and the President drew the attention of members to the fact that the date of the annual competition had been altered from December to January, thus giving rather more time for the preparation of prints. At the conclusion of the usual business, Mr. G. E. THOMPSON gave a most interesting account of a trip to the Riviera, taking as his title,

## THE RIVIERA, ANCIENT AND MODERN.

The lecture was enlivened with many witty passages, personal anecdotes and experiences, and was listened to with rapt attention. The pictures were, as usual, up to Mr. Thompson's high standard of excellence, some of the cloud studies being very fine.

## FORTHCOMING EXHIBITIONS.

1899.		
December 8, 9 .....	Hove Camera Club. C. Berrington Stoner, 24, Holland-road, Hove.	
" 8-18 .....	American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.	
" 11-Jan.1900	Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.	
" 27-30 .....	Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.	
1900.		
January 29-31.....	Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.	
April 3-7 .....	Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.	

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

THE following applications for Patents were made between November 20 and November 25, 1899:—

- PRINTING FRAMES AND REVOLVING STAND.—No. 23,185. "A New or Improved Combined Photographic Printing Frame and Retouching Stand." Complete specification. Communicated by J. L. Brouse, G. Macay, and F. Quilty. B. HADDAN.
- DEVELOPING APPARATUS.—No. 23,207. "Improvements in Apparatus for Use in Developing, Fixing, Washing, and Drying Photographic Films or Plates." E. J. E. HELIE.
- CINEMATOGRAPHY.—No. 23,217. "An Improved Apparatus for Exhibiting or Displaying a Series of Cinematographic or other Pictures." Complete specification. O. MESSTER.
- ROLL-HOLDERS.—No. 23,223. "Improvements in Photographic Film Roll-holders." Complete specification. W. BEUTLER.
- SHUTTERS.—No. 23,351. "Improvements in Photographic Shutters, Stationary and Movable." W. O. STANLEY.
- FILM CLIP.—No. 23,379. "A Clip or Holder for Maintaining Photographic Films in a Flat or Stretched-out Condition, and for Analogous Uses." A. GROSJEAN.
- CAMERAS.—No. 23,515. "Improvements in and relating to Photographic Cameras." S. D. MCKELLEN.
- PRINT CUTTERS.—No. 23,528. "Improvements in Appliances for Cutting Photographic or other Prints or Paper." J. DAVENPORT.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

## ORTOL.

To the EDITORS.

MEIN HERR,—I also write you to give to you my ideas of the new developer, Ortol Hauff. I do myself consider it one off zie best, equal to mein oll friendt Pyro-Soda, and I now hurry to give particulars of mein own experience. On die hottest days off zie past summer, I make much development with die Ortol, having before used nearly always the Pyro-Soda. I find with die Ortol that I have zie more latitude, zie more control, zie use of zie one solution for many plates, zie plain fingers and odder good things. Beelow I giv the results, all done with the one 8 ozs. developer.

Off Plates .....	5000
" Films .....	2500
" Transpare .....	2000
" Brom Prints .....	250
" Enlargements .....	10
Total .....	9760

I also find zie developer after use as above quite as goot, but not so rapide.

With friendly greetings, I recommend myself to you in the best way possible.—Alleways,  
Antroff Strass, 64, Berlin.

HENDRICH SAPT.

To the EDITORS.

GENTLEMEN,—Mr. Welford's paper on "Ortol" is most interesting, but I think his formulæ are rather puzzling. The mixture of "parts" and grains is difficult to follow. For instance, on p. 756, for bromide paper he advises: Ortol, 1 part; soda,  $\frac{1}{2}$  part; sulphite, 1 part; water, 1 part; and about 20 grains of bromide. If the part taken is 1 ounce, we have here  $3\frac{1}{2}$  ounces. How much bromide must we add? In a previous paper he mentioned so many grains "per ounce." If he means this here, we shall have more than sixty grains, which seems a very large amount. I hope he will explain, as I am anxious to try this developer for bromide papers.—I am, yours, &c.,

C. E. F. N.

To the EDITORS.

GENTLEMEN,—Re Mr. Welford's article in your last week's number. Possibly I am very dense, but I fail to understand the composition of the above developer. 1 part ortol; 1 part water;  $\frac{1}{2}$  part soda; 1 part sulphite; 20 grains bromide; about  $3\frac{1}{2}$  parts total. Thus, if I want to make 9 $\frac{1}{2}$  ounces of developer, do I take 3 ounces ortol! 3 ounces water! 3 ounces sulphite!  $\frac{3}{4}$  ounce soda! 60 grains bromide?—I am, yours, &c.,

NOVICE.

## MASONIC LODGE FOR PHOTOGRAPHERS.

To the EDITORS.

GENTLEMEN,—May I trespass upon your valuable space to give further prominence to the above scheme, which has already been most favourably received by many London Masons, but to bring about the successful fulfilment of the idea we require not only the support of London Masons, but of the provincial ones also?

I shall be glad to receive the names and addresses of all who are willing to support such a lodge, so that I can communicate with them as to a preliminary meeting to discuss details.—I am, yours, &c.,

WM. E. DUNMORE.

110, Shaftesbury-avenue, London, W., December 1, 1899.

## THE ECLIPSE PHOTOGRAPH AT THE LATE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

To the EDITORS.

GENTLEMEN,—I am afraid that I cannot avail myself of Mr. Bremner's offer in your last issue. Probably my last letter to you will explain to that gentleman the precise objection which I have made to the photograph in question, and you may think that the subject is used up. I will, however, write a few words in case you may be disposed to allow further discussion on the subject.

Mr. Bremner's letter explains a good deal which I could have no knowledge of. It is abundantly clear that the exposure he gave was such as any one conversant with the subject could have told him would not result in a picture of the eclipse. As he does not give the necessary data for determining the ratio of focus to aperture, or the plate used, I cannot say how much the plate should have required, but it is evident that the exposure was a somewhat full one for clouds, and must have entirely reversed the sun's image. That is not strange. What is so is that any photographer should have supposed that the source of light and heat should have been truly represented by a black disc. I have observed many solar eclipses; possibly I began to do so before Mr. Bremner was born, and I do not think, though it is now some years since I left India, that my acquaintance with the subject is quite forgotten in that country, so that it will not be difficult for Mr. Bremner to satisfy himself that my assurance is not without some justification, when I repeat that the picture exhibited is not a representation of the phenomenon of a partial solar eclipse anywhere; it fails in the truth of the very thing it purports to depict. And that others who have followed the same procedure should have arrived at the same erroneous result does not prove its truth. I am quite satisfied with the statement that the enlargement is *bona fide* (though I acknowledge that I had a suspicion that the clouds were from one negative and the eclipse from another), but I fancy that photographers generally, when they get a reversed negative, either destroy it or keep it as a curiosity. In this case the photographer has enlarged it and exhibited it as a true picture, and he seems still to argue that it is a true representation of what took place.—I am, yours, &c.,

J. F. TENNANT, Lieut.-General R.E.

Clifton-gardens, Maida-hill, W., December 1, 1899.

## ADDRESS OF A SCULPTOR.

To the Editors.

GENTLEMEN.—We saw in your issue of the 1st instant your reply to initials "W. D." re carving busts from photographs. We would venture to ask if you could kindly place us in communication with your correspondent. We have executed work, figure and otherwise, in several of our English cathedrals, and in many leading churches both in London and the provinces. We have had the honour to recently erect the statue of the Queen in our local college, and the whole of the carving and sculpture in the Cheltenham Ladies' College was intrusted to us.

We are exhibitors at the Royal Academy, and one of our last works was a statuary marble-bust of one of our English admirals. This, we trust, is a sufficient proof of our *bona fides*, and we should be glad to hear further of what is required.

Thanking you for your kindness,—We are, yours, &c.,

H. H. MARTY & Co., Sculptors.

Sunning-end, High-street, Cheltenham, December 5, 1899.

To the Editors.

GENTLEMEN.—There is a querist in your last issue who asks for a person who can model busts from photographs. A Mr. Ivor Thomas, Waterloo-street, Swansea, is a gentleman who is exceptionally clever at this work.

I have seen several of his productions, which were strikingly true to the originals.—I am, yours, &c.,

CHAS. H. EVANS.

12, St. Helen's-road, Swansea, December 4, 1899.

To the Editors.

GENTLEMEN.—Mr. D. A. Tonelli, Chatfield-road, Croydon, is known to me as being experienced and clever in carving busts from photographs. An excellent example of his work can be seen in the Croydon Town Hall.—I am, yours, &c.,

HECTOR MACLEAN.

34, Birdhurst-road, Croydon, December 1, 1899.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

C. W.; POSITIVE, and others.—In our next.

ADDRESS OF A SCULPTOR.—Mr. W. E. Meadows, of 59, Scott-street, Bootle, Liverpool, writes: "I can show specimens of work done in plaster and marble from photographs."

ADDRESS OF SCULPTOR.—MR. LOUIS SHOTS (Waverley House, Ockers-street, C.-on-M., Manchester) writes: "I undertake to model and carve any bust after a photograph. I am a gold medallist of the Royal Academy of Antwerp, Belgium, and established here at Manchester."

PHOTOGRAPHY IN THE EAST.—EGYPT says: "Can you tell me what the light is like during February and March in Egypt and Palestine for snap-shot work? Does it compare with our summer, and what exposure and stop should be recommended?"—In reply: Some reader who has had experience of Eastern photography may perhaps oblige our correspondent with a few hints.

TINTED DEVELOPER.—B. STONE says: "I made up a fresh batch of ten per cent. pyro solution with sulphite the other day, and it is quite a pale sherry colour. On using it, I find it work all right in every way. What I want to know is, if the negatives developed with it will be as permanent as those made with a colourless pyro solution?"—Yes, the tint in the solution will have no influence on the stability of the finished negatives.

LANTERN SLIDES.—AMATEUR LANTERNIST sends us three lantern slides and asks our opinion of them. He says that he got a friend to put them into his lantern, and he tells him they are too dense, but it was only an oil lamp. What he wants to know is, how they would do if the lime light were used? They would be much too opaque for any light, and, moreover, they are veiled. The higher lights should be bare glass. Over-exposure and over-development are the chief faults.

DISGUSTED ONE.—We doubt if you have any remedy, as it does not appear that you were asked to submit specimens, &c. Our view is, that as you sent them at your own risk you have no case.

ENLARGING.—W. C. J. writes: "I have a lantern by — & Co. with four-inch condensers. What I want to know is, if, in enlarging with it from quarter-plate negatives, should I use a quarter-plate rapid rectilinear, with which they were taken, or a half-plate rapid rectilinear, as I have both?"—Either will do, but it will be impossible to evenly illuminate a quarter-plate negative with a four-inch condenser. One of five-and-a-quarter to five-and-a-half inches is the smallest that will do that.

CLEANING PAINT FROM GLASS.—W. & C. say: "In the spring we stippled over the glass in the roof of our studio with white paint to keep the sun out. This has now changed to quite a yellow and stops off a deal of light, can you tell me how to get it off in the easiest way?"—Apply a strong solution of crude carbonate of potash—pearl ash—and after a time the paint can be washed off. Of course, if any of the salt comes in contact with the paint on the sash bars, it will act on that also.

SPOTS ON NEGATIVE, &c.—OLD READER says: "Please find enclosed a piece of negative. I am troubled with these spots, brown spots, on many of my best negatives lately. 1. Will you, please, let me know the cause? 2. Is Wellington P.O.P. (special) so permanent a paper as any other P.O.P., viz., Imperial, Ilford, &c.?"—1. The cause of the spots is that the hypo salts were not eliminated from the film in the first instance. Then it was printed from when there was moisture in the film or in the paper. 2. Yes, we should say so.

ADDRESS WANTED. STUDIO BUILDING.—"Will you please tell me (1) the address of the Gem Dry Plate Company? 2. I have built a studio out of an existing building, and, as it is only sixteen feet long by eight feet wide, is there any drawback save, of course, lack of room? The roof is a span one, and is all glazed. It is eight feet high up to the eaves, the south side being boards, whilst the north side is all glass except two feet of skirting. Do you think it will answer?"—In reply: 1. Willesden Green, N.W. 2. Except for its circumscribed dimensions, it will answer very well.

RESIDUES.—T. WILSON writes: "I have just collected my residues for the year. The ash from the paper, P.O.P., weighs six pounds and a half. Will you tell me about how much silver it contains? I am told that I ought to get at least two pounds and a half of silver from the refiner?"—Well, you certainly will not, or anything like it, as there is, comparatively, little silver in it. The greater part of the weight is made up of the baryta coating with which the paper is surfaced, and that is a very heavy material. Without an assay it is impossible to give even a remote idea as to the proportion of silver.

LANTERN LAMP.—LUX writes: "Last year I bought a lantern with a triple wick lamp, and it gave every satisfaction. A few days ago I unearthed it and trimmed it for an evening's show. It gave an excellent light, but the stink—for it was nothing but a stink—from it was unbearable, and the show could not proceed. Can you say how this is to be avoided, as there was no smell, to speak of, from it when used before?"—The cause, doubtless, is that the lamp is dirty from last year's oil not being out and off it before it was put away. Thoroughly clean the lamp, both inside and out, and put in new wicks, and we have little doubt it will be as satisfactory as it was at first.

BAD TREATMENT.—EMPLOYE says: "In the spring I made an agreement with a photographer, for a year, at a certain weekly salary. Last week he gave me a week's notice, as he said the business would not warrant him in keeping me on during the winter. When I reminded him of our agreement, he said he was very sorry, but could not help it, and he would give me an excellent reference. Can I not hold him to the agreement, as he has plenty of money?"—Yes, if you had a written agreement but not without, we are sorry to say. Yours is not an exceptional case with unprincipled employers. They often engage men in the spring, for a year certain, and then discharge them when the season is over.

DRYING MARKS; AGREEMENT.—COLLODION says: "1. Sometimes in drying, a line negative turns light and thin, though previously quite opaque. Process, wet collodion, intensified with lead and ferricyanide, followed by ammonium sulphide. 2. I have a three years' agreement with my employers, in the event of a voluntary wind-up, could I claim wages for any uncompleted time? In the event of liquidation I believe the firm cancel all engagements."—1. Faulty manipulation, probably imperfect washing between the different operations in intensifying. 2. If the company cease to exist, we do not see from whom you can recover. We should surmise that the agreement expires with the company.

POISONS AND TONING.—G. BRANDON asks: "1. Whether potassium sulphocyanide, ammonium sulphocyanide, potassium ferricyanide, and potassium ferrocyanide are poisons within the meaning of the Pharmacy Act? 2. Please give formula for a toning and fixing bath, which will keep for some time in usable condition in one solution. 3. In toning, can platinum be substituted for gold? If so, in what proportion, and is platino-chloride or potassium chloro-platinate the better salt to use?"—1. Neither of the salts named is specially mentioned in the schedule of the Act; it, however, says, "Cyanides of potassium and all metallic cyanides." 2. All the published formulae will keep for some time, though not for long. Better keep the gold separate, and add as required for use. 3. A formula for platinum toning is given on p. 1064 of the ALMANAC for the current year, and on p. 1096 of that for 1900.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

Edited by THOMAS BEDDING, F.R.P.S.

THE Thirty-ninth Annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC is now published. The volume reaches the unprecedented total of 1516 pages, and is the largest yet produced. As hitherto, it is issued in paper covers, price 1s.; cloth bound, 1s. 6d.

The frontispiece is a bromide print by Messrs. Wellington & Ward, of Elstree, from a negative by Mr. H. Walter Barnett, of No. 1, Parkside, Knightsbridge. Many other illustrations are also given in the text matter.

Eighty articles, on a great variety of subjects interesting to photographers, and contributed by the principal authorities of the day, form a feature of the volume. The other sections are "Epitome of Progress during 1899," "Patented Inventions of the Year," "Miscellaneous Information," "Practical Notes and Suggestions of the Year," which, with the large collection of formulæ, tabulated matter, and a great deal of other information of use to all photographers, places at their disposal,

for constant reference, a fund of technical knowledge which is not to be found in any other photographic annual.

\* \* The 1899 Edition of the Almanac (20,500 copies) was entirely exhausted within three months of publication—a fact without precedent in the history of photographic publications.

\* \* Of the 1900 Edition just issued nearly 17,000 copies were disposed of on the day of publication: an increase of between two and three thousand as compared with last year. It is probable that the entire edition will be out of print within a few weeks from date.

## EX CATHEDRÂ.

THE distribution of our annual ALMANAC, which has been accomplished this year with unexampled rapidity, always brings us a very great number of congratulatory letters from its readers, and during the last few days tradition has been well sustained in this agreeable respect. It is a sincere pleasure to us to know that the book increases in public appreciation from year to year, and we are glad to have so many recognitions of its value to the photographic world; but, amidst the feelings of delight which the letters of ALMANAC readers have caused us, we have to own to a touch of sadness at the absence from the volume of many honoured names which death and sickness have robbed us of. Four stauncher supporters of this JOURNAL and its ALMANAC in the old days than Dr. R. L. Maddox, W. K. Burton, W. B. Bolton, and Canon St. Vincent Beechey (to name some of the more prominent absentees of this year), it would be difficult to find. Happily, the first-named is still left to us, though we are sorry to say that illness keeps the pen out of his hand; but the other three have fallen before the Great Leveller. Still the record of their work is left for us to profit by, and it is with pride we reflect on the fact that, during the thirty-nine years of its existence, the most illustrious workers in photography have given the world the benefit of their knowledge through the pages of the ALMANAC.

\* \* \*

An interesting note on the use of curved plates in Stellar photography has been published in an American contemporary,

which says that Professor J. A. Brasher has developed some of the curved plates on which he photographed the sky one night recently when the meteors were expected to appear. While the night was very bad for photographic purposes, the pictures of the stars which he obtained were excellent. He said that they covered ten times the area that was possible with ordinary plates, and the pictures of the stars were well defined and continued clear to the edges of the plates. The time and labour which were expended in preparing to photograph the meteors was not wasted, because it was shown that curved plates are the proper thing for astronomical photography and have opened up new possibilities in this field.

ONE would have thought, considering the heavy punishments that have from time to time been inflicted, that the traffic in obscene photographs had died out, but it does not seem to have done so. On Saturday two men were remanded from the Marylebone Police Court on the charge of procuring and selling books and photographs alleged to be obscene. More than one prosecution has been instituted for showing indecent "living pictures," and we were pleased to record, last week, a disavowal from the Secretary of the Mutoscope Company that some objectionable pictures that had been shown were by his Company. However, some living pictures have been exhibited at some of the music halls which, if not exactly indecent, were extremely vulgar. It is a great pity that such a thing should be, as it will tend to bring this class of picture, now so popular, into disrepute amongst respectable people. The same kind of thing obtained with the stereoscope when it was at the height of its popularity years ago, and was in a great measure responsible for its then decadence. Although not actually obscene, many of the pictures were of exceedingly vulgar character, and many ladies would refuse to look into a stereoscope, not knowing what might meet their eyes. It is to be hoped this will not be the fate of living pictures, the production of which and their exhibition is now so highly remunerative.

"DICKENS' Land," in the neighbourhood of Lincoln's Inn and Clare Market, where so many of his characters were taken from, is fast disappearing to make room for London's improvements. Still the Old Curiosity Shop is not yet touched, though it is ready for demolition. Now another landmark is in jeopardy. The Bull, at Rochester, where the Pickwickians adjourned on their first visit to that city, and where the ball took place which was attended by Mr. Tupman and his friend Jingle, and at which Mr. Jingle offended Dr. Slammer, is shortly to be sold at auction. When sold, it is highly probable that the Bull will be pulled down to give place to a more modern building. We call attention to this sale, as many photographers may like to secure a photographic memento of the old place as a reminiscence of Charles Dickens. Doubtless, the Photographic Record Association has already secured photographs of the "Bull."

STILL another accident with the cinematograph, which might have ended in a serious catastrophe, has been recorded. The account says that during a cinematograph entertainment at Farnborough, Warwickshire, "some films caught fire. The lanterns were soon blazing, and it was feared that the cylinders would explode. A panic ensued, and some people were knocked down and trampled upon, and windows

were smashed by people trying to escape." The report adds that, fortunately, order was restored, and the people escaped without serious injury. These continually recorded accidents are regrettable, as they show either gross carelessness or ignorance on the part of the operators to whom the displays are intrusted. Cinematograph shows have been given at most of the London music halls nightly for months together without a mishap, and it is noteworthy that it is only at minor entertainments that these accidents happen.

It is not from the mere blaze-up of a few films that the danger arises, but the panic and stampede that generally follow, when people are sometimes crushed to death, or seriously injured, as in the Paris catastrophe. We have from time to time been promised new films for photographic purposes to take the place of celluloid, which are not combustible, and some seem to be near at hand. But will they be suitable for the cinematograph? A film for this purpose must be free from granularity, perfectly flexible, and as transparent as the present celluloid films. If a film of this nature were available, it would be a small fortune to the introducer, for there is little question that it would quickly supersede the present combustible celluloid, and thus do away with County Council inconveniences. Indeed, if as good as celluloid, it might lead to a prohibition of its use altogether at public entertainments. Who will be the fortunate inventor of such a film?

WE give on another page a brief report of the Judge's finding in the case recently tried at the Yarmouth County Court, in which it was sought to establish the revolutionary doctrine that the right to the negative vested, not in the photographer, but in the sitter. It is satisfactory to note that his Honour decided in favour of the photographer, and thus we have a further confirmation of past judgments to a similar effect. All's well that ends well, and we are very pleased to hear that in this particular case the article we published a few weeks ago, enumerating the instances in which decisions had been given in favour of the photographer, was instrumental in enabling the Judge at Yarmouth to frame a verdict hostile to those who sought to deprive the photographer of all right in his own property.

As the following announcement may interest many of our readers, no apology is perhaps needed to our esteemed contemporary, the *Chemical News*, to whose columns we are indebted for the information: "At the University College, London, a course of eight lectures dealing with the methods of spectroscopy, especially in connexion with the photography of the spectrum, will be given by Mr. E. C. C. Baly, on Friday evenings, at 5.30 o'clock, commencing on January 19, 1900. Fee for the course, one guinea. The following subjects will be treated and illustrated by experiments: The simple theory of refraction and diffraction; the history of the determination of the modern standards of wave-lengths; the prism spectro-scope and its integral parts; the comparison of spectra and determination of wave-lengths visually and photographically with prism apparatus; the grating spectro-scope. Rowland's concave gratings, their mounting and adjustment; the determination of wave-lengths with the grating; photography of the spectrum; methods of producing emission and absorption spectra; fluorescence and phosphorescence."

## THE METRIC SYSTEM.

THE Secretary of the Decimal Association has just issued a list of Board schools in England and Wales that approve of the metric system of weights and measures being taught in the schools under their control, and generally in favour of the introduction of the decimal system into this country. The list comprises eighty-eight Boards, the total population which these bodies represent being over ten millions. This certainly seems very hopeful for the advocates of that almost universal system abroad.

The metric system is making, though somewhat slowly, progress amongst photographers, and many of our dry-plate and paper-makers are helping it by giving formulæ under both the old and metric systems. What somewhat retards the adoption of the system here is the dealers not putting the weights and measures on the market at similar prices to those charged for them according to the English system. But there is no reason why that should be so. The one costs no more than the other to make. The measures, by the gradulators, are charged according to the number of graduations, and not according to the system, whether drachms or c. c. Furthermore, as we have pointed out before, for a slightly additional cost, one set of either weights or measures may be made to serve for both systems.

We have a set of three glass measures graduated on both sides, one according to the metric system, measuring from 1 c. c. to a litre on the one side, and from 10 minims to the quart on the other. The cost of these was the same as the ordinary measures, *plus* that of the extra graduations *pro rata*. We have also a set of weights with which we can weigh from one centigramme to three hundred grammes—about ten ounces; these in a box, with a receptacle for each weight, from the gramme upwards, and the smaller ones in a closed nest by themselves, which cost about four shillings retail. They are of Continental make and are very accurate. On these we have stamped, with a punch, their equivalents in English grains and ounces. Thus we have one set of weights and one set of measures that serve for both systems. If the dealers would put similar weights and measures on the market at popular prices, they would, doubtless, find the business remunerative, and they would certainly help to make the metric system, by which all Continental formulæ are given, universal amongst photographers.

We might here remind our readers that, in order to lend practical support to the progress of metrology, we have for the past two years expressed most of the formulæ given in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC in metrical as well as Imperial equivalents. Of that course many expressions of approval have reached us, and we have also noticed that some of the dry-plate manufacturers who had not hitherto done so have since sent out their formulæ dually expressed—a course that must be found convenient by many foreign photographers.

In the ALMANAC which has just been published we have some further remarks on the needless difficulties which hamper the adoption of the metric system, and we have thought that the reproduction of the substance of those remarks in these pages would not be inappropriate, as they might attract additional attention to the matter.

In the ALMANAC article we appeal for help in securing the general adoption of metric units to dealers both wholesale and retail, and we point out that many of the former class are agents for foreign firms who supply some of our most generally

used chemicals, whilst others are necessarily chemists themselves, and these are familiar with the metric system, even when they do not use it in their business. The weights and measures used by photographers are largely made abroad and imported, and there ought to be no difficulty in getting one sort more than the other.

We further remark that, as regards weights, indeed, there is practically no difficulty if the purchaser is content to wait a few days, but there is some as regards measures of capacity. Those which are most generally offered, as far as our experience goes, are narrow and cylindrical, and are not suited to the wants of photographers; they are too tall for their bases, and hence are easily knocked over in a dark room, and they are, besides, difficult to clean satisfactorily. A photographer, too, does not want the same accuracy in all parts of the scale; small quantities require to be measured with more accuracy than large, and all ends are best gained by a conical form of measure, rounded at the bottom for facility of cleaning. Corners and projecting portions should be carefully avoided, especially such small hollows as if from broken bubbles in the blowing of the glass, which defects we have met with. If retail dealers could bring themselves to keep a small stock of these articles, and place them conspicuously on view, adding to the numerous placards in their shops one calling attention to them, they would help greatly to popularise them; some, indeed, we hope, would go further, and explain the advantages and convenience of the system to their customers.

So much for the means of apportioning the materials when we have got them; but there is another way in which help may be given. It may be thought that it is easy to weigh out any portion from a bottle, and that it does not matter how much the bottle contains. This is not quite the case, however. Some chemicals are so bulky that it is difficult to weigh them; others are liable to deteriorate rapidly when a partly used bottle is left for some time. Pyro, for instance, which is so generally used, is open to both of these remarks. Of course, ingenuity overcomes the inconvenience of weighing, but recently a search for a convenient holder for performing this operation was unsuccessful. Practically, pyro is only available in England in ounces, and many formulæ for its use are so given as to need no break of bulk. Now, an ounce contains 28·4 grammes, and it is quite certain that the foreign producers do not put up this chemical in ounces for home consumption, nor do they use the ounce in their manufactories; they have simply suited themselves to the market they desired to reach, and what was recently the English law. Now that the use of metric units is legal, it is to be hoped that pyro and other chemicals will be made available in such parcels as are used abroad, and that such will be available in dealers' shops. An example shown by some of the large dealers would soon be followed. At first, no doubt, the demand for such parcels might be small, but the cost of keeping a small stock of weights or measures and chemicals in convenient bulk for use with metric formulæ would not be great. Our photographic schools, too, might do a great deal to push the use of the common-sense formulæ on the metric system.

Finally, we urge on those who communicate formulæ for the ALMANAC (and this also applies to the JOURNAL), that they should give their proportions for a litre of solution. Apart from convenience of comparison, there is the great facility for making just what quantity one requires, which is singularly wanting in many of the recipes.

We have reached the limits of space assigned to this article, but we shall recur to the subject. If we can be instrumental in persuading all photographers to use the metric system, and the trade houses to supply the proper weights and measures, material assistance will have been given towards its general adoption.

**Induced Radio-activity.**—M. and Madame Curie are still pursuing with ardour their investigations into the radio-activity of the hitherto unknown body they have extracted from the uranium ore, pitch-blende. They have recently communicated to the Academy of Sciences a paper describing a remarkable and unexpected property possessed by the radiations—a power of inducing radio-activity in a variety of other bodies submitted to the radiation from polonium and radium. These substances are powdered and placed on a horizontal plate, and a few millimetres above it the material to be tested, placed on supports. In this manner the substance is proved to become impregnated as it were with the radiative effluve, and for several days the intensity diminishing rapidly, but not disappearing entirely for some time. It was necessary to use very strongly radio-active material, that employed by the investigators being from 5000 to 50,000 times more active than uranium, which, it will be remembered, was the substance to which attention was first drawn by Becquerel for its radiating power. In the present investigation the aim was to discover whether the induced radio-activity was to be attributed to vapour or powder thrown off from the originating body on to the induced matter, but though arguing from analogy such emission was to be expected, yet the conclusion arrived at was that the result was actually owing to induced radiation, and not to transference of radiating matter. The final experiment, which seemed conclusive, was made by enclosing the polonium or the radium material in a metallic box with a thin aluminium bottom, and then placing plates of the various substances in external contact with the aluminium. The plates became endowed with a radiative power from ten to seventeen times greater than uranium, a radiation entirely different from the secondary Röntgen radiation, which ceases the moment the Röntgen rays are prevented from striking the emitting body, while with the new property under discussion, the radiation persists, as pointed out, for days.

THE question naturally arises, Have M. and Madame Curie separated a new element or new elements, or not? and, to answer it, M. Eugene Demarcay has, in a paper published in the *Bulletin* of the French Chemical Society a paper describing the results of a spectroscopic examination of several specimens sent to him. The first received had a radiating power 70,000 times that of uranium. In the photographic spectrum obtained he finds a series of new lines quite as strong as the strongest of those from the accompanying barium, and ten other fainter lines, so faint as to render their origin doubtful, so that, before publishing them, he would prefer to wait till he obtains a still purer form of radium.

**The "Missing Star Shower."**—From some highly interesting letters in *Nature* last week it would seem possible that the expected meteor shower may actually have occurred, after all, but in the daytime. Professor N. Story Maskelyne first heard of the observation in Wiltshire, and asked the observers to put in writing their own descriptions of the phenomena they witnessed. The three letters are published. They are all from what may be termed one party of casual observers, but they really appear to have seen, and through a slight mist, an immense number of falling stars. A fourth extract from a letter is from another quarter (in Essex), and describes a similar appearance.

NEVERTHELESS, many astronomers hold the opinion that the stars which should have appeared the middle of last month may be expected in November of 1900 or 1901. It is calculated from the descriptions given that these daylight-seen meteors could not have

been Leonids, seeing that the constellation of Leo would have been well below the horizon at the time, while the observers coincide in stating that the meteors seen all appeared to start from one point.

IN view of their possible appearance next year, it may be well to note that any camera observers can add very much to the scientific value of their negatives if they obtain spectrographic trails by a simple addition possible—merely a prism or a diffraction grating, which, as *Nature* states, can now be purchased, of practically perfect make, very cheaply, of sufficient size to cover the lenses of ordinary cameras. After the camera has been focussed, the prism or grating can be very simply attached to the hood of the lens, the whole then constituting a small prismatic camera, which will give the spectrum of any meteor whose image falls upon the plate.

### THE NASCENT SILVER THEORY.

[Translated from the *Photographische Correspondenz*.]

A LIVELY exchange of opinions has recently taken place concerning the theory of the formation of the invisible (latent) developable image, brought about by exposure of silver bromide to light. The silver sub-bromide theory advocated by me, amongst others, was attacked, and an attempt was made to set up in its place the idea of the primary formation of nascent metallic silver (nascent silver theory). I entered several objections, and in various articles, which appeared in this periodical, I supported the silver sub-bromide theory upon the ground of demonstrated, experimental facts.

Professor Abegg, the principal advocate of the nascent silver theory, now finally concedes, in an article upon this question,\* which appeared in the *Physikalische Zeitschrift* (vol. i., 1899, p. 32), that the nascent silver theory, by itself, is insufficient to explain the whole of the photographic phenomena, and thinks that the experiments "clearly permit the possibility of a combination of both theories."

Professor Abegg is therefore in complete agreement with the view I entertained more than ten years ago. I might be satisfied with this but for the fact that the researches I have recently made, in consequence of this discussion of the question, have led me to further divergences from Professor Abegg's opinions. At the present time I find it impossible to attribute to the nascent silver theory, even in the sphere of secondary action, that marked influence in the formation of the developable latent image which I formally thought might be the case.

I was then of opinion that the primary latent image consisted of sub-bromide, which formed metallic silver under the action of the developer. The metallic silver in contact with silver bromide then caused further noticeable reduction of metallic silver. This, in addition to the first process, I considered of great importance. Professor Abegg was of opinion that nascent silver was the sole cause of the formation of the latent image, but he now abandons the idea and returns to my old conception, which he at first contested; but recently I have had to recognise that this action by contact, upon which Professor Abegg sets special importance, is quite secondary. Spectrum photographs, taken with optically perfect spectral apparatus (concave gratings) giving fine definition, have convinced me of this. Multitudes of closely crowded, perfectly sharp lines may thus be photographed, which, upon development, attain considerable density without spreading laterally in the same degree. This is proof that contact action exerts less influence than the penetrating energy of light.

However, I think much has been gained, if the untenable nascent silver theory has at least been partially abandoned by its originators. Efforts are now being made in the *Archiv für Wissenschaftliche Photographie* to save the "nascent silver theory," at all events in name. The publication now uses the expression "nascent silver" (vol. i. p. 109) to indicate generally the substance of the latent image, whether the idea be that of sub-bromide or metallic silver.

I think it is inexpedient to include in this manner under one collective name two distinctly different ideas. Nascent silver and the theory associated with it were at first used in distinct opposition to the sub-bromide theory.

The proof of the untenable nature of the theory should not be made the ground for applying the term "nascent silver theory" to some other thing which may be more easily defended. The nascent silver theory

\* In the paper Professor Abegg overlooks the fact that meanwhile the indestructibility of the latent image has been proved in connexion with gelatino-bromide of silver as well as collodion.

comprehends such a clearly defined photo-chemical idea, that it is inadmissible to give the name offhand a different meaning.

Whether the nascent silver theory be false or true, the name is attached to a certain opinion, and it is contrary to the necessary precision of language to change meanings without adequate reason. If the "nascent silver theory" cannot be sustained, we should abandon the use of the term "nascent silver" for the denotation of something which differs from its original meaning.

DR. J. M. EDER.

#### RODINAL AS A DEVELOPER.

Of this particular developer more has been used in my own practice since its introduction than of any other developing agent, although it is by no means the only one I use, for, indeed, there are but two of the late introductions, diogen and kachin, which have not been tested, and tested as I prefer to test any such matter, not by using it on two or three specially exposed plates, and upon the results basing one's opinions of its usefulness or otherwise, but by making up some amount of it in stock solutions, and employing it for plates, exposed in the ordinary manner, out of doors, and under such conditions as one's work is mainly undertaken under, and continued over some reasonable length of time; for, however clever a photographer the experimenter may be, it is impossible to pick up and at once employ any strange reducing agent with the same facility as those which constant use has given complete control over. The more is this so when any radical change has been made either in the manner of its working or nature of the resulting negatives given.

Each new developing salt introduced to us comes with its accompaniment of high-strung praise over its wonderful qualities, then a few letters, and, it may be, one or two articles appear, followed later by the usual crop of complaints. So was it with Rodinal, but its chief, if not only, sin seems to lie in some supposed difficulty to obtain dense negatives. No greater mistake could be made, for density may be built up as readily with it as by any other developer, if it be desired and means taken to ensure it.

What I like about it in particular is the simplicity and readiness with which any variation is possible, for, being highly concentrated, and in one solution, at a moment's notice either negative-making, bromide enlargements, or lantern slides may be dealt with, the only difference being a more copious dilution with water of this developer is advisable when paper or slides are being treated than when making negatives, with regard to which, by the way, some considerable correspondence lately has been carried on in the photographic press relative to that highly important topic. Should a developing solution be used more than once? It produced some interesting and certainly amusing reading, one side holding, with true British doggedness, that, after once having done its work on a plate, a developer should be consigned to its resting-place, the dark-room sink, while others asserted the contrary, and for a time right merrily waged the wordy warfare.

To me it was intensely amusing, for just about the time I had five dozen exposed plates awaiting development, and hitherto it had been my practice, when anything like a batch of, say, one dozen or more were dealt with at the time, to mix up my developers, and proceed gaily to pass one plate after another through, until either the whole batch were finished or development became slower, when the addition of ten or twenty minims from the stock bottle set matters going briskly again. Such had been my practice in a general way, and, in spite of the woes and evils supposed to follow such a practice, past experience seemed to justify the risk, and four dozen exposed plates were in one evening transformed into forty-seven decent, respectable-looking negatives, most, if not all, of which possess some measure of success, if Mr. Chapman Jones's definition of that desirable article, the perfect negative, be a correct one, viz., that it is pure silver in clean gelatine, for all through the series of twenty-three whole-plates and twenty-four quarter-plates. So far as diversity of subject, exposure, and so forth would allow, they presented a uniformity of colour, density, and general good quality which left little to be desired, and certainly no cause of complaint; yet for this batch I had used the selfsame solutions right through, with only, as already pointed out, one or two additions from the stock solution to revive its developing action.

Some slight discolouration necessarily takes place when a number of plates are passed through the same developer, whatever it may be composed of; but, with rodinal, and indeed pretty nearly any of those reducing agents of kindred nature, this appears to have no detrimental effect upon plate or film submitted to its action, which is certainly not the case when pyro is employed; and where this particular developer, pyro, is the one used, there can be no doubt of the better plan being to treat each plate with a freshly made solution, for the simple reason oxidation quickly transforms a pyro developer into a dirty, muddy concoction, unless a large percentage of sulphite has been employed as a preservative.

One reason why difficulty arises, when developing plates with rodinal, to obtain ample density, is because, as a rule, it is used considerably diluted, and time is not allowed for it to build up sufficient density, which, by the

way, is done somewhat slowly, if the developer is being used weak, where, for any reason, exposed plates are first treated with dilute rodinal, after such detail has been brought out as may be thought desirable, density may rapidly be obtained, either by adding rodinal from the stock, or transferring the plate to another dish containing one part of rodinal to ten or fifteen parts water, to which has been added sufficient potassium bromide to hold in check its action. In this manner density may be obtained quite as quickly and effectually with this developer as when employing any other. In the same way, where plates submitted to it are found to have been much over-exposed, they may likewise be transferred to the strong and restrained developer just referred to, when development will proceed more correctly, and the results should prove quite satisfactory.

On the other hand, where either excessive contrasts in the subject itself or brought about by insufficient exposure, having been given the plate, the effects of this evil may be much reduced by employing a developer considerably weaker than normal; for instance, one part of rodinal may be added to sixty or ninety parts water. A batch of plates may then be submitted to it, and practically we have "stand development," for which I have found nothing more convenient when dealing with small sizes, such as quarter-plate, than one of the glazed pot tanks sold by all dealers, and used for fixing or aluming negatives in. A dozen plates may then be treated at once by placing them in the grooved tank, with sufficient of this dilute developer to cover them; then a tray or lid, or, indeed, anything, being placed over the tank, one may go about other matters and feel perfectly certain no harm is likely to occur if, from time to time, examination be made, and such negatives as have progressed sufficiently be fixed and washed in the usual way. One matter, however, should not be forgotten, plates developed with this or similar reagents are rather deceptive as to density, and need to be carried apparently further than where pyro, or even hydroquinone, has been used. So also, for some reason or other, when developing in the manner just referred to, they are better for being carried slightly further than when developed with a solution of normal strength. Curious as it seems, the fact remains, and should be noted when commencing stand development.

Used for developing prints on bromide paper (contact or enlarged), it gives pearly greys and good rich blue-black, while for lantern-slide work it needs development carried very far indeed before the shadows become blocked, when the developer is used reasonably dilute, say 1 in 40.

A curious effect was noted some time back while making a series of lantern slides, many of which were given full exposures, and so developed as to get the brightest red colour possible. The plates were Paget's slow, and, having towards the end become rather weary, I hurried up development of the last ten or twelve slides by adding a few drops of rodinal to the slow-acting developer in which they had been. The small transparencies at the moment under treatment were very red in colour, but after the slight addition of rodinal it rapidly cooled down to a pleasant brown, and having several duplicate exposures, by varying the amount of rodinal added to the developer, specially intended to produce a maximum warmth of colour, showed that, as it was added in greater or less quantities, so did the vivid red slide rapidly alter in colour, and, if pushed by the addition of much rodinal and allowed time, they seemed to turn to a rich warm black. Some of the resulting slides treated in this manner turned out a beautiful rich warm sepia, while others, having had just the same lengthy exposures, but developed straight away in rodinal, gave a warm black image, and I can well imagine, to first partially develop for bright red colour, then cool it down, by a brief immersion in rodinal developer, would prove a useful method of obtaining any desired warmth of colour between black and red entirely by development, with considerable certainty and in a speedy manner.

A commendable feature also about this developer is its sociability, for it will mix with and work in conjunction with any other developing agent I have used, and, from its all-round usefulness, should find a place on the shelf of every practical photographer, be he professional or amateur.

W. THOMAS, F.R.P.S.

#### HINTS ON BROMIDE PRINTING.

BEFORE the members of the Leeds Camera Club, on Wednesday, December 6, a lecture was given by the Rev. W. H. Dick, of the Manchester A.P.S., on the subject of "Bromide Printing." The lecturer first dealt with the negative, and told his audience that if they made up their mind to print in bromide—one of the most useful processes at this season of the year—it was imperative they should also make up their mind to produce a suitable negative. By a series of diagrams he showed how a negative of many degrees of density, from opacity to clear glass, must act, that the ideal negative should have its deepest shadow printed black when its highest lights were just beginning to degrade, and not before. In some forms of printing a different range was necessary, but, for the best class of bromide work, he might liken the gradations of the negative to the keyboard of a piano, taking all the upper and middle scales, but leaving out those of the base. The production of such a negative was clearly demonstrated, showing that a weaker developer than usual ought to be adopted, and, though every detail and gradation were relative in a properly exposed and developed plate, yet the light was able to pass through these gradations and correctly represent them. Following on to the

printing he advocated the use of the oxalate and iron developer, and, though its use necessitated the clearing acid bath, yet it was capable of producing the best work, and with considerable control, and this could be adapted to suit the particular class of negative. By a series of prints he showed that, with a light at a uniform distance, exposures of  $1\frac{1}{2}$ , 3, and  $4\frac{1}{2}$  seconds produced, with a given strength of developer, certain results; while with exposures of 3,  $4\frac{1}{2}$ , and 6 seconds, and a weaker developer, a different result was obtained, for, while the  $4\frac{1}{2}$  seconds in the first set clearly indicated over-exposure, the 6 seconds in the other set was about equal to the one of 3 seconds in the first.

The extremes in the making up of the developers were for the first:—

Saturated sol. oxalate potash .....	4 drachms.
" iron sulphate.....	1 drachm.
Ten per cent. sol. potass. bromide .....	1 drop.

For the second—

Saturated sol. oxalate potash .....	12 drachms.
" iron sulphate.....	1 drachm.
Ten per cent. potass. bromide .....	3 drops.

Of course, any modification between these two could be adopted, and the lecturer recommended them to make trial exposures on a given negative to determine for themselves which gave the best result, and make a note of it. Then, by comparison with that negative, any other could be dealt with later, and they would have some certainty of producing results which, if not absolutely equal to platinotypes, certainly came very near them; while as to permanence, he could show them prints of four years ago which had not altered in the least.

#### AN IMPROVED FERRO-PRUSSATE PROCESS.

We append the principal details of Mr. A. F. Hargreaves' method of producing modified "blue" prints upon cotton, linen, paper, or other suitable textile fabrics.

The designs, says Mr. Hargreaves, are fixed upon any of the above-mentioned materials by the deposition or precipitation of a pigment, lake, or colouring matter heretofore unknown to the art and science of photographic printing.

The pictures produced are unchanged by exposure to sunlight, are novel and beautiful in colour, and will stand a boiling soap solution.

This invention dispenses with the use of any of the salts of gold, platinum, silver, or other precious metals so much used in photography, and is a development or extension of the well-known ferro-prussiate process.

Two chemical substances, ferric ammoniac citrate and potassic ferri-cyanide, are each separately dissolved in water, in about the following proportions:—140 to 175 grains ferric ammoniac citrate in 3 ounces water; 120 to 160 grains potassic ferri-cyanide in 3 ounces water. The above solutions are then mixed.

The solution of these two materials is brushed over a piece, say, of bleached cotton cloth of any required size, or the pieces of cloth may be dipped into the solution, the operation being done in a dark place.

The excess of solution is now pressed out by means of, say, pressing rollers or any other suitable method, and in this condition the sheets are carefully dried in the dark.

The sensitized sheets are now used for printing in the usual way known to photographers and engineers from photographic negatives or drawings made on thin transparent paper or cloth. After printing, it is only necessary to wash out the unchanged or soluble material by means of water, whilst the changed portion which is blue, being insoluble, remains.

It is important that the blue prints should be well washed in water in order to eliminate all unchanged chemicals; and, in order to do this more effectually, I may digest them in a dilute solution of hydrochloric acid, and afterwards well wash in pure water.

As stated in my provisional specification, I make no claim whatever to the above process, but use it or its equivalent for the purposes of my invention, which, though dependent on having this photographically produced blue print as a starting point, is a distinctly after-process.

Now, the essence of my invention consists in utilising the iron contained in the blue colouring matter as above produced by actinic light, and making it the medium or base for the formation of another colouring matter, which is more intense, beautiful, and permanent.

In other words, I use the iron in the blue as a mordant in the same way as calico-printers purposely fix oxide of iron on cotton cloth as a preliminary in the dyeing of purples, blacks, greys, &c.

When cotton cloth on which there has been fixed an oxide of iron is subjected to certain dyeing materials, such as alizarine or logwood, purples and blacks are produced, the first-named material producing a well-known and highly esteemed coloured lake known as madder or alizarine purple, and is one of the most permanent colouring matters known.

Now, my chief novelty consists in utilising the fact that the blue colour referred to, being an iron compound, acts as if oxide of iron alone were fixed on the cloth, and it can therefore be used as a mordant, or, in other words, as a basis for the formation of purples and blacks.

For the purposes, therefore, of my invention I use a photographically produced blue print on any suitable material, though I prefer cotton cloth.

The blue prints are subjected to the action of a dye bath containing any or all of the following dyeing materials added to a considerable volume of water: madder, alizarine, purpurine, or logwood.

The blue prints are preferably entered into the dye-bath at a temperature of about 100° F., and the temperature gradually raised in thirty or forty minutes to the boiling, and agitated during the whole time. They are then well washed in clean water, and afterwards treated to a boiling soap solution. They are then well washed, dried, pressed, and (if desired) starched, and mounted in any desired manner.

It must be understood that, in mentioning the three first-named materials, I may use any preparation or modified form thereof. For instance, madder is a root of a plant called *Rubia tinctorum*, and contains alizarine and small quantities of purpurine, but it has been almost entirely displaced in the arts by artificial alizarine; notwithstanding this, it may in some cases be preferable to use it and certain preparations therefrom, such, for instance, as garancine, which was formerly prepared from madder in large quantities.

In the same manner there are certain modified forms of purpurine, such as flavo-purpurine, any of which I may use. In fact, alizarine of commerce contains more or less of all these materials.

According to my most recent experience, I prefer to use commercial alizarine containing this material in its purest form.

#### GRAVURA PLATES AND PAPER

BEFORE the Gospel Oak Photographic Society, on Tuesday, December 5, Mr. Baldwin, representative of the Paget Prize Plate Company, demonstrated to the members of the above Society the capabilities of the Gravura paper, lantern plates, and opals, manufactured by his firm. At the outset of his demonstration, Mr. Baldwin made a few remarks relative to the chief characteristics of these materials, from which it appeared that they were of the "gaslight" development order, that is to say, that all the operations connected with the production of lantern slides or prints could be conducted in an ordinary room, lighted by gas, thus dispensing with the dark room and ruby lamp, which was necessary when using ordinary bromide paper or lantern plates. The chief advantage of the paper lay in this fact, but there was another important consideration which was not to be lost sight of, and that was the ease with which colours could be obtained on either paper or lantern plates, ranging from cool sepia to red chalk. These were obtained by increasing the exposure beyond that required for black tones, and at the same time using the developer very much diluted and restrained, and in the case of the warmer tones, using in conjunction with the diluted restrained developer a solution of ammonium carbonate. It was the invariable rule that, the warmer the tone desired, the longer should be the exposure, and the weaker and more restrained the developer. For black tones, however, the concentrated or normal developer should be used without the addition of ammonium carbonate.

Regarding the exposure required, nothing definite could be said, as this would vary with the source of light, character of the negative, and distance between the two. As to the source of light, for amateur use nothing better could be wished for than magnesium ribbon, though for black tones ordinary gaslight would answer, the protracted exposure required for the warmer tones somewhat putting it out of court when these were desired. For the professional photographer the incandescent gas light was the cheapest, and two large-size burners would be ample. As a guide to the exposure necessary, it might be mentioned that one or two minutes might be given with a negative of average density at a distance of about four inches from an ordinary gas flame, or from half an inch to an inch of magnesium ribbon burnt at about 12 to 18 inches from the negative. Hard negatives would require to be nearer, soft negatives further from the ribbon or gas flame; this distance was only approximate.

If warm tones were required, then the quantity of magnesium ribbon might be increased from  $2\frac{1}{2}$  to 5 inches (according to the colour required), or the exposure to the gas flame increased to from ten to twenty minutes.

The developer, which was recommended by the makers of the paper, and which had been found to give the finest result, was a metol-hydroquinone one made up as follows:—

Hydroquinone .....	35 grains.
Metol .....	14 "
Soda sulphite .....	1 ounce.
Soda carbonate (crystals) .....	$1\frac{1}{2}$ "
Potass. bromide .....	20 grains.
Water to make up to .....	29 ounces.

This was the normal or concentrated developer for black tones.

The ammonium carbonate solution, previously referred to as used when warm tones were desired, was prepared as follows:—

Ammonium bromide .....	1 ounce.
Ammonium carbonate .....	1 "
Water to make .....	20 ounces.

The developer for warm tones might vary, as in the following :—

FOR COOL TO WARM SEPIAS.

Concentrated solution .....	1 ounce.
Ammonium carbonate solution .....	.50 to 60 minims.
Water to make .....	60 ounces.

FOR WARM BROWNS TO REDS.

Concentrated solution .....	1 ounce.
Ammonium carbonate .....	½ "
Water to make .....	8 ounces.

FOR RED CHALK.

Concentrated solution .....	10 ounces.
Ammonium carbonate solution .....	½ ounce.
Water to make .....	20 ounces.

The lantern plates required no alteration of the developer for black tones, but, where colours were required, the quantity of water to be added to the developer should be only one-half of that required for prints. With this exception, the manipulation was exactly the same. The opals were to be used exactly the same as the paper.

One point not to be overlooked was the difference in the time of development. For black tones this might be only about thirty seconds, but in the case of red chalk it might amount to five minutes, or even more.

At the conclusion of his remarks, Mr. Baldwin exposed and developed prints, lantern slides, and opals, showing the full range of tones which might be obtained, the beauty and simplicity of attainment of which was very much admired by the members present.

In answer to questions, Mr. Baldwin said that Gravura, like all other papers, was capable of the finest results only when used with negatives which suited it best, which in this case should be of a soft character, with plenty of detail in the shadows. As to the permanency of the process, it had only been on the market for such a short time that nothing could be said from the practical aspect, but in theory everything was in favour of its being quite permanent.

## FILM PHOTOGRAPHY: THE LATEST PROCESS.

The latest process of film photography is due to Mr. Albert Hofmann, of Cologne, who gives the following description of it :—

Smooth, well-gummed, even baryta-weighted or similarly prepared papers, or woven materials, or other flexible bodies serving the purpose, are coated either on one side or both sides with substances soluble in alcohols, ethers, or benzines, such as resin alone or in combination, but at all events not made brittle, but softened through being dissolved in fatty oils or turpentine. The best results are obtained with simple solutions of shellac, gum sandrac, or mastic, with the addition of fatty or drying oils, *e.g.*, castor oil, also with turpentine or the common pine-tree resin, with suitable additions to make and to maintain the product soft and ductile.

Just as good are the soluble albuminous bodies of cereal origin, such as vegetable gluten.

After this film is taken up and is dried on, one applies a gelatine coating, to which is added a hardening medium, alum, chrome alum, or the like. With a suitable concentration, one can get a sufficiently thick coating in one operation, otherwise one must repeat the operation often enough to give the final product the requisite strength, in order that it may act as independent negative without any later strengthening. Under certain conditions, gelatine can be applied to both sides of the paper, and, after being dried, coated with a layer sensible to light, whereby it is rendered serviceable for using on both sides. In this case the original paper must be blackened. The laying on of the sensitive sheet is accomplished in the well-known manner, as well as the development, fixing, and washing of the negative after exposure.

Before the negative is dried, it is placed for a few minutes in a spirit bath, after which the paper easily loosens itself from the foundation. In order that the separated negative may be hardened and softened, it is now immersed in alcohol containing five per cent. of glycerine and five per cent. of formalin.

The film coming out of this alcoholic glycerine bath is then dried, suitably pressed on to a scrupulously clean glass plate, varnished, and copied, exactly like every other negative.

It can, however, be used as an independent film, without transfer to a glass plate.

## A ROLLER-BLIND DARK SLIDE.

MR. HENRY MAJOR has submitted to us a model of a dark slide of novel construction.

In place of the ordinary rigid shutter a blind passes over rollers. It has an aperture for the insertion and exposure of the sensitive film, the blind being operated from the back by a small projection, or cord, moving with great ease, and the whole being encased in aluminium.

The slide can be made square with scarcely any increase of size, and, used with a square focussing screen, obviates the employment of a reversing back.

A feature of the slide is the extreme rapidity with which the change from focussing to exposure is effected. This might render it useful to portrait photographers, as they can by one rapid movement displace the focussing screen and expose the plate.

The operating part can be drawn sideways, upwards, or downwards, according to circumstances, the latter movement being an advantage in the larger sizes, when it is often difficult to draw a shutter upwards.

It can be easily and inexpensively adapted to any camera or used with an adapter devised by Mr. Major, which, dispensing with a focus cloth, has a focussing chamber which reflects the inverted image right side up. The focussing screen is fixed on springs which automatically keep it in register. The focussing chamber and screen open outwards for the insertion of the dark slide, which drops easily in, and, the back being closed again, the spring screen holds the dark slide in position, the only part of it remaining exposed being a small projection at the back for operating the blind. The danger of light getting between the camera and the dark slide, and between the draw-out shutter and the plate, is entirely overcome.

Another form of focussing chamber consists of a collapsible spring, which moves outwards on opening the back of the camera, and has a hooded aperture for viewing the screen.

It is claimed for this dark slide and adapter that, for quickness of focussing and exposure, it nearly approaches the non-focussing snap-shot camera; that there is no danger of shifting the camera when inserting or removing the dark slide, or exposing the plate, or of partial exposure, or of partly removing the slide when exposing.

The whole system is clever and practicable, while the roller-blind dark slide is singularly compact, neat, and ingenious.

## A NEW PRINT-WASHER.

THIS has been invented by Mr. G. T. Harrison, who employs an ordinary metal body or barrel, A, which he mounts on a suitable stand, B. The feed water inlet consists (see figs. 1 and 2) of a series of holes or perforations, C, which extend along the bottom of the barrel, A, from end to end, and are inclined so as to produce a rotary movement of the water within the barrel.

The waste-water outlet consists of a parallel series of holes or per-

FIG. 1.

FIG. 2.

forations, D, which are preferably slightly larger than the inlet holes, C. The two series of holes run closely parallel, the inlet holes, C, and the outlet holes, D, being preferably arranged at alternate intervals (see fig. 2), so that the rush of water from each inlet hole passes between the adjacent pair of outlet holes, so dislodging any print having a tendency to settle

over the outlet holes, *n*. By this means the outlet holes, *n*, cannot become choked by the prints as they are carried round the washer.

Separate inlet and outlet conduits, *m* and *r*, in connexion with the inlet holes, *c*, and outlet holes, *n*, run longitudinally beneath the barrel,

FIG. 3.

FIG. 4.

*A*, the inlet pipe, *c*, being preferably carried from the top of the washer, and the outlet being siphoned over at *n*, so as to discharge at the bottom and so prevent splashing.

In place of the inlet holes, *c*, a fan feeder, *k* (see figs. 3 and 4), with a semicircular opening to the inside of the barrel, *a*, may be employed. In this case the pipe, *c*, and inlet conduit, *m*, are dispensed with.

As the interior of the washer forms an unbroken curved surface with no projecting parts, the prints or plates are therefore not liable to damage during the washing operation.

#### PERMANENT ALBUMEN PRINTS.

MR. D. BACHRACH, in an American contemporary, gives the following method of obtaining black tones on albumen paper:—

Take the regular albumenised paper supplied to photographers, not thicker than the ten kilo Rives (the single albumen is better than the double-coated), and immerse it in a silver solution of the strength usually employed for floating it, for about the same length of time, and dry it. Fume with ammonia precisely as with the regular process, and then print on the back. If the paper is free from albumen spots on the back, a plain paper print of the very finest quality is the result. I recommend a silver solution about sixty grains to the ounce in strength.

To tone the same, if a rich, warm tone is desired, use the usual gold toning bath considerably weaker than that used for albumen paper. It must be remembered also that the depth of printing and the washing before toning must be the same as for albumen prints. The most important part, however, where failure has most often resulted, consists in the thorough fixing of the prints. A solution of hyposulphite of soda from six to eight ounces to thirty-two ounces of water, fresh every day, and fully twenty minutes' immersion therein, with frequent moving, followed by an hour's washing in running water or frequent changes in still water, will, if faithfully carried out, ensure prints almost absolutely permanent, and even less liable to deterioration in the whites than platinotypes.

Should pure black platinum tones be desired, the first toning to the warm black must be followed with the platinum bath, precisely as with the Aristo platino paper, only a stronger solution is required. In that case, however, the prints should be immersed in water made slightly alkaline with soda, and then rinsed or washed a short time in clear water before fixing. The prints thus treated are the most permanent of any prints excepting platinotypes and carbons that I know of, exceeding the former in the permanence of the whites.

We have here a process capable of yielding a wider range of tone and

individuality than any of the methods at present in favour, and the prints by this method have the additional advantage of giving an excellent surface, one peculiar in its advantages, for the colourist, by reason of its albumen backing. The print is really all through the body of the paper, and is practically indestructible by the ordinary elements. There are many advantages in this method that will commend themselves to the photographer, which it is not necessary to mention, and which will become apparent to each one by constant use.

In connexion with platinum toning I wish to state that photographers are wasting a good deal of money in purchasing the platinum toning solutions sold under various names, which are not a whit better than the formulae published in the journals time and again. A fifteen grain bottle of the platinite salt costs forty-five cents, and will tone as many prints, as uniformly and with the same character of tones as the eighty cent and one dollar bottles of the prepared solutions. I have had a number of them analysed, and this is about or near what they were found to contain:—

Chloro-platinite of potass. ....	15 grains.
Citric acid.....	72 "

An improvement is made if about fifty grains of common salt are added to the above and all dissolved in one or two ounces of water. This will keep indefinitely, and a small portion can be used and diluted with water for each batch of prints. It will be at least a good practical lesson to try this process of printing, if nothing else is gained.

#### A NEW SYSTEM OF ELECTRIC LIGHTING FOR PORTRAITURE.

MESSRS. G. & W. MORGAN, of 393, Union-street, Aberdeen, are introducing a system of electric lighting for studio portraiture, for which they claim the following advantages: Large area of dispersion and diffusion, from 108 to 180 square feet; greatly increased rapidity; entire freedom from eye strain (softer light); economy of current, and ease of manipulation.

The system has to be fitted permanently into the studio, on the opposite to the daylight glass, resembles an ordinary window for daylight, and is fitted with a special kind of obscured glass. The light used is from arc lamps automatically fed, and so arranged behind the obscured glass, and fitted with a system of diffusers and reflectors, that all the rays from the arcs, both direct and reflected, pass through the obscured glass into the studio, one mass of soft, but very actinic, light, every part of the glass frame having an equal amount of illuminating power.

The arc lamps are compensating in their action, so as to work well in series, and are economical of current; they also carry a large quantity of current, if necessary, for rapid exposures.

Messrs. Morgan further state that, using full power with a rapid plate, and lens working at *f*-3, children can be taken in quarter-second exposures. The light may be increased or diminished at the will of the operator so gradually as to cause no distraction of attention on the part of children and others. The working parts are all out of sight except the switch-boards.

We have had submitted to us specimens of large portraiture produced by the aid of Messrs. Morgan's system of electric lighting. They are certainly fine examples of this class of work, and are barely distinguishable from effects obtained by means of natural illumination.

#### THE RIGHT TO THE NEGATIVE.

The case of Harbord *versus* Brewer & Co., came on at Yarmouth County Court last week. It was an adjourned claim by Mr. A. T. Harbord, solicitor, for the return by the defendants of several photographic negatives.

The action was heard at the last Court, the point involved being whether negatives are the property of the customer or of the photographer. The defendants had bought the negatives in dispute with numerous others at an auction of Mr. Watson's effects on Regent-road, and plaintiff, hearing of this, claimed the negatives as his property, declaring that they never should have been sold by a third party. His Honour at the last hearing was inclined to the opinion that the law was, that negatives were the property of the customer, but on the representations of Mr. A. F. Clowes, the defendants' solicitor, his Honour consented to reserve his opinion till the subsequent Court.

His Honour now gave judgment, and said he had looked at the cases. He could not find any case in the High Court that practically decided the point whether a photographer was entitled to the negatives or not, but cases in the County Court which bore upon the point showed that the photographer was entitled to the negative. His verdict must, therefore, be for the defendants.

Mr. Clowes remarked that the case had excited great interest in the photographic world, and he asked his Honour to grant him a special fee, as the matter was of public interest. He was sure, if his Honour awarded him 10s., Mr. Harbord would be glad to pay, as he got his legal advice on the point free, gratis, and for nothing.

His Honour, however, said he could hardly certify that the issue was one of public importance.

## A NEW FOCUSSEING DEVICE.

This has been devised by Mr. J. Fleck, who describes it as consisting of two parts or "focussing bags,"  $m$  and  $n$ , connected together by means of concentric rings,  $k_1$  and  $k_2$ , that are rotatably fitted together. The part,  $m$ , which has preferably the form of a bellows, is attached at its front end to the back of the camera. The part,  $n$ , is provided at its rear end with a mask,  $q$ , which is shaped to fit the face, and which is formed with sight holes directed towards the focussing plate mounted in the camera frame,  $b$ . These sight holes are preferably fitted with eyepieces,  $o o$ . In this manner the two advantages which are found to be incompatible with each other in other apparatus, namely, the complete exclusion of light and the capability of using eyepieces, are here both obtainable in one device.

For the purpose of enabling the focussing to be effected with still

greater sharpness, the part,  $n$ , is made of soft light-excluding fabric.

If it is desired to view more fully the outer portions or edges of the image on the focussing plate or screen, it is merely necessary to remove the eyepieces,  $o o$ , together with the mask,  $q$ , resting normally in a fork support (not shown in the figure) out of the said support, and to move the same around the entire contour of the image within the limits of the ring,  $k_2$ .

The forked support is mounted on the upright,  $c$ , in which also the outer ring,  $k_1$ , is fixed. The upright,  $c$ , can be made to slide for the purpose of adjustment in guides fixed to the camera frame, and, when the correct distance from the focussing plate has been found, the upright,  $c$ , is clamped in the said guides by means of a spring or pin.

## ELEMENTARY PERSPECTIVE AND COMPOSITION.

At the meeting of the London and Provincial Photographic Association on December 7, Mr. W. R. Stretton read a paper on the above subject.

He said that, even amongst advanced workers, there often existed a very hazy knowledge of the scientific principles underlying the production of a picture, and especially in regard to their application at the moment of taking a photograph, and that, while most people possessed an inherent power of appreciation of pictorial result, those who can produce from the abundance of nature such results are lamentably few. "In a multitude of counsel there is usually wisdom," and, as his remarks were primarily addressed to the beginner, he had no fear of criticism, but would welcome anything that might remove ignorance of facts and add to his own knowledge. The usual lines of instruction with their apparent jangle of technical terms are best avoided, if one would interest the average aspirant to society medals; therefore, the subject must be treated from merely a mechanical aspect, what a composition is, and how perspective comes into play in producing it. Composition is only the arrangement of complex forms in order to present them to the eye as a single idea. Perspective is a mechanical process involved in reaching it, and is a technical name for certain natural laws that regulate the size and appearances of all objects, according to their distance and intensity of illumination. Perspective drawing is the mechanical rendering of objects in the same way in pictorial forms, with the essential difference that the objects are shown upon an imaginary surface at an arbitrary distance from the eye. A pinhole camera is a perfect perspective recording instrument, giving a rendering in precise values according to the

distance of objects before it. The substitution of a series of lenses for the pinhole provides the power of altering the size without the appearance of the objects, or, in the opposite way, it gives the power of altering the distance and appearance without altering the size.

Does the camera lie? The camera and lens tell only such lies as its users direct and concoct, but the machine is labelled instead of the man. Photographers of life-long standing have criticised prints, and ejaculated, "Too short a focus lens was used;" but it is out of the power of a man to tell from any strange print or negative the focal length of the lens used. A well-known man has said of a quarter-plate photograph that it was taken with a short-focus lens, whereas it was taken with a nine-inch lens. For particular subjects each has better qualities than the other, but the general principles involved are simply those affecting the angles, and consequently light and shade effects. That, where objects lie parallel with the plane of the picture, short-focus lenses are best used is well known, and long-focus lenses where objects lie obliquely, though the question is determined by the lighting.

When once I said (continued the lecturer) that there was no more art in the average photograph than the amount that existed in the object in front of the lens, the judgment exposed was considered rather harsh, but the fact remains that the really good composition amongst the vast number of exposures is lamentably small. Pictorial composition is a natural gift not freely bestowed. It is the power of selecting and recording objects in such a way that, when the whole be viewed, the balance and proportion of parts allows the eye to take in the whole as a complete subject. The photographer must consequently, upon the precision of the facts as shown by his lens, use far greater power of selection in making a composition than an artist, and he must of necessity oftentimes include absolutely objectionable facts such as would be excluded by his brother of the brush.

An effective illustration is shown in the slides upon the screen, the first showing two unconnected spots interfering with each other and irritating the eyes; the second has a connecting line by which the irritation is removed, and the eye appreciates the whole, for photographers' composition is one continued struggle to make isolated objects and masses into some general scheme. They are continually finding out that visual values and perspectives differ from those recorded by our lenses and our photographic plates, so that one comes to the conclusion that, when opticians can give us a lens that will work like that of the eye, any one with a camera will be able to mechanically produce compositions, for the difference between the two lenses explains everything. The eye can only focus a point, but that at any distance, and everything beside that point is not clearly defined. The photographic lens is supposed to be specially made to focus everything beyond a certain distance, so that, to show the objects in some way that only a definite idea be conveyed, the eye becomes a necessity.

Space prevents reference to the extensive and valuable hints upon the arrangements of masses and lines, triangular, square, and circular forms, breaks and their uses, light and shade, the limitations of the photographic plate in its imperfect transcription of varying intensities, questions of foreground and point of view, sky and cloud, and their suitability, &c., but, in conclusion, Mr. Stretton urged the importance of aiming as near perfection in pictorial results at the initial stage of exposing the plate rather than to trust to the power of alteration in the print. It is more truthful to nature and photography alike.

Mr. Philip Everitt wished first of all to disabuse some of the members of the idea voiced by other of his fellow-members that he made any claim to artistic capability, and especially with the camera. The amount of matter laid before the meeting made it difficult to select any one thing for comment, but he thought Mr. Stretton might have laid greater stress upon composition, in so far as masses of light and shade were concerned as opposed to lines. Lines were very important, and they certainly did tend to give the observer of the picture an indication of the artist's intention; but masses of light and shade and their arrangement were more important in a photograph than mere lines. One must consider in what way one is most likely to get particular effects, by attention to lines or by attention to masses of light and shade. He believed by the latter, and it was one of the faults of photographers of the present time that they were not direct and simple enough in what they did. They strove far too much for detail, and too little for breadth of effect. This led him to the conclusions of the Chairman, who said that there was no analogy between the eye and the lens. He saw, however, a strong analogy, and the functions performed by the two were very similar. The defect lay rather with the photographer in getting certain planes in focus and suppressing other planes. There may be two or three facts in a picture which one wants to connect, and they lie in different planes. The problem is how to delineate these masses sufficiently, and yet suppress, perhaps, the intervening spaces. It is often a practical impossibility, and the work breaks down because of too much detail in parts not requiring it. Another point on which greater stress might have been laid was this, the function of the horizon and its position in the picture. He well recollected the case of a friend who wanted to take some cloud negatives at the seaside, and who ascended a height under the belief that he would better succeed there than below. He was astonished to find that he got less sky from the higher ground than from below. Many people overlooked this fact. But the lower you want your sky line the

ower must be the camera, and the higher the line the higher the camera. The sky line must always be at the height of the camera or observer.

Mr. Walter D. Welford believed that the motive underlying the lecture was truthful rendering of subjects before one by photography, but he never understood why it was necessary to portray a landscape truthfully at all. If, in looking at a picture, one had exact distances of things, angles of view, and so forth, it would be a different matter. But, as a rule, one had no knowledge of the place or its bearings, the simple question being, Is it pleasing or pictorial or not? It seemed to him that, although underlying principles were helps to pictorial composition, yet there were hundreds of paintings and photographs which please us well, until somebody discovers something about the place and says that it is not in strict composition. He was struck with one slide, of which it was said that a certain tree would be better removed. Now, if he were convinced of this, he should have blocked it out or done something else to satisfy his conscience. There was no advantage in the merely strict delineation of a scene, as, unless it be known, it makes not an atom of difference.

Mr. Stretton did not see any reason to excuse his criticisms of the slides, which by some were thought to be severe. Having started out to work on certain definite lines, his purpose was to prove it by illustration, but he was willing to admit that few people could supply thirty slides such as those shown with such a high average perfection, and they were very creditable to their maker. In talking about lines to the exclusion of masses, he confessed that it was a case of getting into studio cant. Lines of a composition are made up of masses, and the successful handling of these makes the beauty of the composition. Mr. Stretton thoroughly believed that Mr. Welford could not understand the necessity for truthful rendering of a subject. He had heard him say that the ultimate object was the print, but here he had to disagree. If one is going to take a photograph, and it is not to be anything else, well, there is an end to art in photography.

#### NEWCASTLE AND NORTHERN COUNTIES PHOTOGRAPHIC EXHIBITION.

THE Annual Exhibition and *Conversazione* in connexion with the Newcastle and Northern Counties Photographic Association were held last week in the Barras Bridge Assembly Rooms, Newcastle. There was a large attendance, over which the President (Mr. G. B. Bainbridge) presided, and he was supported by the following gentlemen: the Rev. Principal Gurney, Messrs. T. Bainbridge, G. L. Snowball, W. S. Corder, Percy Corder, W. E. Cowan, John Watson, Barkas, Spence, Milburn, and others.

The President extended a very warm welcome to Principal Gurney, who, he said, was ever ready and willing to help forward any objects, social or scientific.

Principal Gurney, who was received with loud applause, said he thanked them for the honour they had done him in inviting him to open that Exhibition and *Conversazione*. It was the more gratifying to him because he ventured to believe that it was no mere personal compliment, but rather a recognition of the position and work of the University College of Newcastle, and, therefore, a courtesy which his colleagues as well as himself highly appreciated. Although the Newcastle-upon-Tyne and Northern Counties Photographic Association and the Durham College of Science could hardly be described with accuracy as kindred institutions, there were many reasons why they should be drawn together in cordial sympathy and mutual sincere respect. Photography, when properly understood, was built up upon two great foundations—science and art. Both departments were, he ventured to say, represented at the local College in a manner satisfactory to students and creditable to this great city, the metropolis of the north, and certainly no one could look round that splendid Exhibition without realising that those members who had produced those excellent examples of their art must have availed themselves of the latest resources of science, and also that they must have had considerable practical acquaintance with the principles and laws which had been indicated by the greatest artists of the world. He had to acknowledge himself to be a mere outsider in photography. The exigencies of a busy life had left him little time and few opportunities to indulge in what might have been to him, as it had been to many of his friends, the most delightful of hobbies; in fact, he believed he laboured under the not uncommon disadvantage of having been born too soon.

After referring to photography in the sixties, the Principal went on to say that chemistry had made enormous strides; physics had advanced even more rapidly; but the most striking and most important progress had been made on the artistic side of photography. It was evident that mere manipulators of apparatus might be little more than mechanics, or even intelligent recording machines; but photographers had recognised the splendid capabilities of their art, or perhaps it would be more accurate to say that they had raised the old handicraft into an art. Nothing was more noteworthy in such exhibitions as the present than the profound artistic knowledge displayed in many pictures. Nowadays no wise person would venture to depreciate the importance of studying the rules of art, and be content to trust to what was called their good taste. The good taste of an untrained mind was a very uncertain

quantity. Genius might here and there establish a few exceptions, but they only served to prove the rule. The majority of men and women ought to be taught what to admire, and why they ought to admire it. They might all like in their own way what was beautiful, but the most intense sense of pleasure in the perception of beauty was reserved for the artist. To copy nature by a mechanical process could give none of that intellectual delight which was obtained from the consciousness that they had obtained the best result from certain given materials—that by putting their mind and heart into their work they had taught the world a truth that it would be the happier for knowing, and by a creative idea they had increased the perception of beauty. No thoughtful person could study the photographs displayed in the Exhibition without the conviction that they were works of art; there could be traced the working mind of an artist. They were not the result of the labour of a mere mechanic. Of course, their production required an operator familiar with his materials and trained in every stage of the scientific process. Every art was learned by assiduous practice, and photography was no exception to the universal law. The photographer must know how to make the best of his subject—how to set forth his picture so that it might present the most pleasing appearance without any sacrifice of truth. It was absolutely necessary that he should be able to manage light and shade. Chiaroscuro gave breadth of effect, it prevented attention being attracted to parts meant to be subordinate. There could be very little satisfaction in a picture where there was no unity, where the artist had failed to produce a complete and harmonious whole. In a well-thought-out picture there should be balance as well as contrast. One of the chief sources of pleasurable impressions was undoubtedly variety; without variety of line, and of form, and of light and shade, the composition was apt to become dull and monotonous; but in the effort to introduce variety they must never allow themselves to lose sight of the charm of simplicity. No amount of ingenuity of intricate contrivance would compensate for the absence of repose. Lastly, it should be remembered that suggestion was often more effective than emphasis. It was more important to know what to omit than what ought to be included. A knowledge of what must be sacrificed was even more necessary than the perception of intrinsic beauty of details. No artist could fully grasp the capabilities of his art who had not thoroughly familiarised himself with its limitations.

In conclusion, Principal Gurney congratulated the Association upon the success which had crowned its work, and the utmost he hoped to do was to stimulate and encourage young beginners to try to realise the dignity of their art, to cherish high ambitions, to express noble thoughts by intelligent work, to the delight and instruction of all to whom it might come, and thus to add to the happiness and progress of their generation.

The members' competition produced a large entry of work, in which a marked improvement on former years was visible.

The following are the awards: Silver medal, Mr. W. S. Corder, portrait; bronze medal, Mr. G. B. Bainbridge, cattle; Mr. G. L. Snowball, landscape, with sheep; highly commended, Mrs. Burrell, portrait; Mr. Hendry, landscape; Mr. W. B. Ellis, landscape; and Mr. Brady, landscape.

In addition to the members' competition work, there was also a representative loan collection, including work by Messrs. Craig Annan, Wellington, Wade, Charles Reid, Lodge, Worsley Benison, Thomas, L. and H. Selby, Cockerill, and many others.

#### THE CAMERA CLUB.

FROM the December number of the Camera Club *Journal* we extract the following interesting announcements:—

We regret to have to announce the retirement of Mr. Basil Lawrence, who has for a long time ably edited the *Journal* under very considerable difficulties. Owing to his resignation, it has been decided that the editorship shall be placed "in commission." After this month the *Journal* will, therefore, be conducted by a small sub-committee.

Several of our members of the Services have received orders to proceed to South Africa. Among them, Major-General Sir H. E. Colville is in command of a Brigade of Guards; Lieut.-Colonel Lysaght is in charge of the Treasury Chest, and, we trust, will be able to find room somewhere for his camera; Surg.-Major Beevor, of the Coldstreams, who did so much good work with the X rays during the Afriki campaign, is again to the front. The cavalry will have the advantage of the experience gained by Major Eckersley in the last Ashanti War. Major Hickman Morgan, D.S.O., has embarked as Principal Medical Officer in charge of the *Princess of Wales*, with a large staff of surgeons, nurses, and men of the R.A.M.C. This ship, which is, doubtless, known to many members as a popular cruising yacht, the *Midnight Sun*, has been completely fitted up as a hospital ship. It is to an expert and scientific photographer and member, the Duke of Newcastle, that the country is indebted for the presentation to the *Princess of Wales* of a most complete apparatus for investigation by means of the Röntgen rays.

We must all welcome among us once again our old friend, Captain Hinde, who, after having distinguished himself as an officer in the service of the Congo Free State, and as the author of *The Fall of the*

*Congo Arabs*, has of late years been in the service of the East African Protectorate, in charge of the Massai tribe, who occupy a district which is really undefined, but is roughly about 250 by 150 miles. His headquarters are at Narrobi; but, as the tribe is nomadic, Captain Hinde is generally on a tour of inspection, and leads also a wandering life. Sport has, fortunately, not been lacking in his district, and as he has promised to give us an evening, describing the country, the people, and the other animals on Thursday, January 25, 1900, we hope that he will also be able to show us some of the results of his powers with gun and camera.

On Monday evening last, Mr. E. J. Humphery, M.A., addressed the members of the Club on the subject of the new oxy-magnesium lamp, the invention of the Platinotype Company, which has already been described in our columns. There was a very large attendance of members, and Captain Abney occupied the chair. In the course of the evening some twenty-four portraits of members and visitors were taken by means of the light, and all the exposures were successful. This is very high testimony to the simplicity and efficiency of the apparatus.

## Our Editorial Table.

### FLORENTINE FRAMES,

Manufactured by FROST & REED, 8 Clare-street, Bristol.

By the courtesy of Messrs. Frost & Reed we have become the recipients of a welcome gift in the shape of a new frame, which they have specially designed for photographic portraiture. It is carved in walnut, to the Florentine design, and has an English gilt bevel flat, proportioned to the size of the frame. The one sent us is for 12 x 10, and the depth of the richly carved frame is three inches, the bevelled flat being nearly another inch. Messrs. Frost & Reed say that the width of the moulding is increased in larger sizes and diminished in the smaller, so that the proportions may always be relied upon for correctness and suitability to the size. Besides the frames carved in walnut wood, the same kind of frame, in carved wood richly gilt, is also supplied.

We have very great pleasure indeed in bringing the Florentine frames to the notice of our readers. The carving is beautifully done, and the frames are neatly made and finished throughout. Portraits so framed might be safely hung in the drawing-room, in the assurance that they would be in complete accordance with the best taste. The Florentine frames should receive a considerable share of patronage from photographers.

### THE BRITISH WEATHER CHART, 1900.

By B. G. JENKINS, F.R.A.S. Large size, 25 in. x 10 in.; post free, 6½d.  
London: R. Morgan, 65, Westow-street, Upper Norwood, S.E.

In this chart the author has forecast the probable weather of each month for next year. A series of mean readings is also given, and the entire chart is based upon the information and data contained in papers previously published. Mr. Jenkins remarks that he is now "able to state that the forecast curves may be relied on as a basis for deducing the general character of the weather of 1900."

### THE INTERNATIONAL ANNUAL OF ANTHONY'S PHOTOGRAPHIC BULLETIN, 1900.

Edited by W. I. SCANDLIN. 312 pp.  
London: Percy Lund & Co., 3, Amen-corner.

Good paper and printing, and numerous well-produced half-tone illustrations from photographs, help to make this a handsome book, and the articles and formulae constitute it as useful as it is handsome. Amongst the European contributors we notice the names of R. A. R. Bennett, C. H. Bothamley, R. H. Bow, J. Gaedicke, M. J. Harding, Chapman Jones, Rev. F. C. Lambert, Rev. T. Perkins, G. E. Thompson, Major-General Waterhouse, and others. The Anthony Annual is full of readable information on photography.

### LEHRBUCH DER PHOTOGRAPHISCHEN CHEMIE UND PHOTOCHEMIE.

#### II. THEIL: ORGANISCHE CHEMIE.

By ALEXANDER LAINER, Professor at the Vienna Technical School.  
R. Lechner, K.U.K. Hof und Universitäts-Buchhandlung, Vienna.

This volume forms the second part of Dr. Lainer's work on Organic Chemistry, and with the first volume on the Inorganic, published some time since, completes a work on Photographic Chemistry of considerable value. The present volume deals with the aromatic compounds, and is consequently of special interest. It brings within its scope all the modern developers, the colour sensitizers, the albumens, and the albumenoids. A very useful appendix deals with the method of determining the constituents of an inorganic salt soluble in water.

## News and Notes.

**PHOTOGRAPHIC CLUB.**—Wednesday evening, December 20, at eight o'clock, "Elementary Chemistry of Photography," by Mr. C. F. Townsend.

On December 21, the London and Provincial Photographic Association will discuss "Old and New Developers." Visitors are welcome at the White Swan, Tudor-street, E.C.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Photo-mechanical Meeting, Tuesday, December 19, at 66, Russell-square, at eight p.m. "Negatives for Three-colour Work," by Captain W. de W. Abney, C.B., F.R.S.

**MR. LYDDELL SAWYER**, of 230, Regent-street, W., is now engaged on a large life-size painting of Mr. John Hollingshead. This is to be presented to Mr. Hollingshead on the occasion of his forthcoming benefit at the Empire Theatre.

**BRIXTON AND CLAPHAM CAMERA CLUB.**—Mr. J. McKinley Milne writes "It is with regret that I have to inform you that Mr. Whittaker has been obliged to resign the position of Hon. Secretary to the above Club on account of ill health. All communications, &c., in connexion with the Club should be forwarded to me at 77, Atlantic-road, Brixton, S.W."

**MR. G. ALBERT SMITH**, F.R.A.S., of St. Ann's Well and Wild Garden, Brighton, asks us to announce that he has made arrangements with the Warwick Trading Company, Limited, 4 and 5, Warwick-court, High Holborn, London, W.C., whereby that firm will, for the next few years, have the exclusive benefit of the entire output from his Brighton factory.

**MR. A. H. BAIRD**, 89, Lothian-street, Edinburgh, desires the present address of Mr. J. Taylor, photographer, who during a period of five months (June to October) was photographing in the districts surrounding Lanark, Haddington, Portobello, Perth, and Cupar Fife. Mr. Taylor is English-spoken, is about forty-five years old, five feet four inches high, has a brown beard, and wears spectacles.

"THE BORDERLAND IN SONG AND STORY."—Under the auspices of the Edinburgh Photographic Society, the President (Mr. Alexander Eddington) delivered a lecture on "The Borderland in Song and Story," in Queen-street Hall last week. Mr. H. J. Blanc, R.S.A., presided, and there was a large attendance of members and friends. During the evening Mr. J. Douglas Young and Mr. George Barclay sang a number of Border songs, and the lecture was illustrated with an excellent series of lantern slides.

**BIRMINGHAM PHOTOGRAPHIC SOCIETY.**—In consequence of severe illness, Mr. F. Rayner will be unable to deliver his address upon "The United States of America," announced for Tuesday, the 19th inst.; but, in place thereof, Mr. J. F. Hall-Edwards, L.R.C.P., F.R.P.S., has consented to give a lecture upon "Colour Photography," dealing with the composition of light, the phenomena of the spectrum, and the latest and fullest development of colour photography. The lecture will be illustrated by Ives's kromoskop lantern, examples of Joly's process, and various interesting experiments.

**AFFILIATION OF PHOTOGRAPHIC SOCIETIES.**—At the Executive Committee Meeting, held at 66, Russell-square, on November 23, Mr. A. Mackie in the chair, the Committee accepted the kind offer of the loan of a lecture upon "Architectural Photography," in respect of the pictorial side of the subject, by Mr. Henry W. Bennett, F.R.P.S., whose lecture upon the technical details of this branch of work has been in circulation for some time. In response to a specific request, it was resolved to ask the Board of Judges to adjudicate upon lantern slides as well as print competitions sent in by the various societies. The position of negotiations for further lectures was laid before the Committee, and steps were also taken with a view to the speedy extension of the sets of lantern slides now available, and the acquisition of some new work.

**ROYAL INSTITUTION.**—The following are the lecture arrangements at the Royal Institution before Easter: Mr. C. Vernon Boys, six Christmas lectures (specially adapted for young people) on "Fluids in Motion and at Rest;" Professor E. Ray Lankester, twelve lectures on "The Structure and Classification of Fishes;" Dr. W. H. R. Rivers, three lectures on "The Senses of Primitive Man;" Professor H. H. Turner, three lectures on "Modern Astronomy;" Dr. Charles Waldstein, three lectures on "Recent Excavations at Argive Heraeum (in Greece);" three lectures by Sir Hubert H. Parry; Mr. W. L. Courtney, three lectures on "The Idea of Tragedy in Ancient and Modern Drama;" The Right Hon. Lord Rayleigh, six lectures on "Polarised Light." The Friday evening meetings will begin on January 19, when a discourse will be given by the Right Hon. Lord Rayleigh on "Flight;" succeeding discourses will probably be given by the Hon. C. A. Parsons, Professor J. Reynolds Green, Mr. H. Warrington Smyth, Professor J. H. Poynting, Major Ronald Ross, Professor Frank Clowes, Sir Benjamin Stone, M.P., Professor J. Arthur Thomson, Sir A. Noble, Professor Dewar, and other gentlemen.

**HOVE CAMERA CLUB EXHIBITION.**—The following is the list of the Judges' awards:—Challenge Silver: Mrs. A. O. Jennings, *Biddy*, No. 208. Class A (open), Champion: Silver, withheld; bronze, Mr. W. F. Slater, No. 3, and Mr. J. M. Whitehead, No. 7; certificate, withheld. Class B (open): Silver, Mr. P. S. Lancaster, No. 96; bronze, Mr. C. P. Stoner, No. 33; certificate, Mr. Douglas English, No. 67. Class C (open), Lantern Slides: Silver, Mr. J. Kearney, No. 129; bronze, Mr. Edgar R. Bull, No. 131; certificate, Mr. Greystone Bird, No. 111; special certificate, Mr. W. Archibald, No. 116. Class D (open): Silver, Mr. W. G. Cotesworth, No. 166; bronze, Mr. Lumley Cator, No. 162; certificate, Mr. H. Cookeon, Nos. 145-148. Class E (Club), Landscape: Silver, Mr. R. C. Foskett, No. 173; bronze, Mr. W. A. Ford, No. 181; certificate, Mr. C. B. Stoner, No. 177. Class F (Club) Marine: Silver, Mr. Douglas English, No. 192; bronze, Mr. R. C. Foskett, No. 189; certificate, Mr. C. B. Stoner, No. 196. Class G (Club), Figure Studies: Silver, Mrs. A. O. Jennings, No. 208, and Mr. Douglas English, No. 212; bronze, withheld; certificate, withheld. Class H (Club), Architecture:

Bronze, Mr. R. Chimes, No. 240; certificates, Mr. D. J. Gadsby, No. 238, and Mr. R. C. Ryan, No. 244. Class J (Club), Lantern Slides: Silver, withheld; bronze, Mr. A. B. Sargeant, No. 250, and Mr. Douglas English, No. 254; certificate, Mr. W. A. Ford, No. 261. Class L (Club), Lantern Slides: Bronze, Mr. A. R. Sargeant, No. 264; certificate, Mr. Douglas English, No. 268.

To the current issue of the *Transactions of the Botanical Society of Edinburgh* Mr. R. A. Robertson contributes a practical paper on the "Photo-micrography of Opaque Stem Sections—Recent and Fossil." Mr. Robertson's method has much to recommend it to all who are engaged in research work or teaching, and who need a method of reproducing accurately the diagnostic characters of timber as seen in transverse and longitudinal sections. Micro sections as usually made do not present enough surface to exhibit, typically, all of the characteristic appearances. Large areas are therefore necessary, and it is to a demonstration of the best method of obtaining these that this paper is devoted. No sectioning is necessary, as only the specially dressed opaque surface of the block of wood is micrographed. This is a distinct advantage where museum specimens are concerned, as the micrograph may be taken without in any way damaging the preparation. A photo-micrographic camera, which is capable of working either vertically or horizontally, is best adapted for the purpose. The microscope accessories are removed, and a half-plate lens is fixed to the front of the camera. The wood specimen is propped up in position in front of the camera, so that the plane surface is at right angles to the optic axis of the apparatus. Focussing is arranged by means of a Welsbach incandescent gas-light, which stands on one side of the apparatus, and finally by means of a focussing glass and magnesium wire. The radiant for exposure is a magnesium ribbon apparatus, arranged like the Welsbach on the opposite side. Mr. Robertson's experiments show that eight inches from the surface of the wood is the best position for the light when exposing. The time of exposure varies with the plate, intensity of light, and colour of the wood. With slow Ifords forty seconds have been found to give very satisfactory results.—Mr. J. H. COOKE in *Knowledge*.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

December.	Name of Society.	Subject.
18.....	Bradford Photo. Society .....	Yorkshire Photographic Union—Loan Collection Lantern Slides.
18.....	Camera Club .....	Photographic and Mechanical Discussion.
18.....	Cripplegate Photo. Society .....	Members' Night.
18.....	Glasgow and West of Scotland .....	Matéria Photographica. W. J. B. Halley.
18.....	Kingston-on-Thames .....	Christmas Card Competition.
18.....	Oxford Camera Club .....	A Trip on the Mediterranean. E. A. Bevers.
18.....	Stafford Photo. Society.....	Photographic Christmas Card Competition.
18.....	Whitby .....	Demonstration: Bromide Enlarging. E. Hall.
19.....	Birmingham Photo. Society ..	A Four Months' Tour in the United States of America. F. Rayner.
19.....	Gospel Oak .....	Demonstration: Carbon Process. W. Beyer.
19.....	Hackney .....	Plates and Papers for Pictorial Work. A. Horsley Hinton.
19.....	Iale of Thanet .....	Negative-making. Rev. F. O. Lambert.
19.....	Redhill and District .....	Demonstration: Printing in Clouds. T. P. Padwick.
19.....	Royal Photographic Society ..	Negatives for Three-colour Work. Capt. W. de W. Abney, C.B., F.R.S.
20.....	Borough Polytechnic .....	Elementary Orthochromatic Photography. E. Sanger Shepherd, F.R.P.S.
20.....	Photographic Club .....	Elementary Chemistry of Photography. C. P. Townsend.
20.....	South London .....	Social Evening.
20.....	Southport .....	Demonstration: Working of the Sandell Perfect Plates and Films. J. T. Sandell.
20.....	Southsea .....	How a Lens is Made. C. P. Goers.
20.....	West Surrey .....	Lantern Night: Members' Slides.
20.....	Woodford .....	Modifying Developers. H. W. Bennett, F.R.P.S.
21.....	London and Provincial .....	Discussion upon Developers, New and Old.
21.....	Oldham .....	Negative-making. Reader, James Whitehead.
21.....	Oroydon Microscopical .....	Conversational Meeting.
22.....	Darwen .....	Prize Slides.
22.....	Leeds Photo. Society .....	Annual Meeting.—Election of Officers.—Exhibition of New Slides by Godfrey Bingley.

### ROYAL PHOTOGRAPHIC SOCIETY.

DECEMBER 12,—Ordinary Meeting.—Mr. Chapman Jones, F.I.C., F.C.S., in the chair.

#### ILLNESS OF MAJOR-GENERAL WATERHOUSE.

The CHAIRMAN expressed deep regret, in which the members participated, that the Hon. Secretary, Major-General Waterhouse, had been unable to attend this meeting, and one or two previous meetings, in consequence of a bronchial affection from which he was suffering, and a general wish was also expressed for his speedy recovery.

#### NEW MEMBERS, &c.

Thirteen new members were elected, and ten candidates for membership were nominated.

The CHAIRMAN announced that Dr. Abbé had been elected an Honorary Fellow of the Society.

#### THE NEXT EXHIBITION.

It was stated that the Organizing Committee for the Exhibition of 1900 had been constituted as follows: Messrs. Chapman Jones, A. Mackie, J. J. Vezey, R. Child Bayley, H. Vivian Hyde, F. C. Lambert, J. A. Sinclair, J. B. H. Wellington, H. Snowden Ward, and J. C. S. Mummery.

#### ELECTION OF AUDITORS.

Messrs. H. Vivian Hyde and W. Thomas were unanimously elected auditors of the accounts of the Society for the current year.

#### THE DALLMEYER FOCOMETER.

Mr. T. Bolas, F.I.C., F.C.S., read some "Notes on the Use of the Dallmeyer Focometer," the instrument which formed the subject of Mr. Dallmeyer's Traill Taylor Memorial Lecture, and which was presented by him to the Society. Mr. Bolas said his principal object was to emphasise the fact that the Society were the owners of the apparatus in question, that members and affiliates had as easy access to it as to the books in the library, and that as much use as possible should be made of it. It was not an unusual or special form adapted solely or chiefly for the purpose for which it was designed by the donor; but it was an optical bench for general or universal service, and would be kept in a room where it would always stand ready for immediate use. He believed that an idea had been expressed in certain quarters that the instrument was so valuable and of so delicate a nature that its use should be subject to a series of regulations so drastic as to be only worthy of the London County Council; he hoped, however, that this would not be the case, for it was better to run the remote risk of slight damage than to fence the apparatus about with restrictions which would prevent its general use. It was a piece of work which any university or technical school laboratory would be proud to possess, considered simply as a rule, it was a very valuable possession, for it was by no means easy to get a good, rigid, graduated system of such length—eight feet. At several international photographic congresses attention has been called to the inaccuracy of the sizes of plates, and it had been suggested that plates which did not closely approximate to their nominal dimensions should be returnable to the makers, and also that there should be a definite limit to the thickness of plates in the respective sizes. Mr. Bolas showed how the focometer could be used for obtaining extremely accurate measurements of the linear dimensions of plates and of their thickness, and said that, if Mr. Dallmeyer had set out with that object in view, he could not have devised a more satisfactory instrument. With regard to its more legitimate purposes, he thought it would be chiefly used by members of the Society for the accurate determination of the focus of lenses, and for locating on the mounts of the lenses the principal planes; and he suggested that those who preferred to work entirely by mechanical methods, and to get their results without calculation, would find it very convenient to employ Dr. Schroeder's method, which, with other methods, he described and illustrated. He proceeded to point out that, if certain additions were made from time to time as required, the Society would be in an altogether unique position as regarded the facilities which it could offer for the examination of lenses. For instance, means might be provided for measuring flatness of field, and for examining a lens for marginal definition as affected by astigmatism.

Messrs. DALLMEYER, DEBENHAM, TALLENT, and LAMBERT, and the CHAIRMAN took part in the brief discussion which followed the reading of the paper.

#### PRINTING TYPES.

Mr. Bolas then read a further paper on "The Origination of Printing Types by Photographic Methods," in which, having explained the method of making printing types from original steel punches, he proceeded to point out the essential difference between the very slight bevel or angle of relief ordinarily given to the face of a type-founder's punch, as contrasted with the irregular hill-like slope of a letter photographed either separately or as part of a printed page. He suggested that the steep slope of the type-founder's punch arose less from the exigencies of printing than by reason of the inconvenience which would arise in casting type if the slope from the face towards the shoulder were less steep, the inconvenience of a less steep slope being most pronounced in the case of faces which come close to the margin of the shank or which oversail as "kerns." He gave manipulatory details whereby small pieces cut from a phototyped sheet might be so mounted as to make serviceable photographic punches, or originals from which electrotyped matrices could be made; and he demonstrated the hand-casting of a type from a photographic matrix. The paper concluded with a suggestion that photographic reproduction might conduce towards a return to the free or writing style for printing characters, and instances were given of cases in which the method would be economical.

#### COMING EVENTS.

December 19, Photo-mechanical Meeting, "Negatives for Three-colour Work," by Captain W. de W. Abney, C.B., &c. January 2, 1900, Lantern Evening, "Round about the Matterhorn and the Aletsch Glacier," by Mr. Henry Speyer.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 7,—Mr. J. E. Hodd in the chair.

Mr. WALTER D. WELFORD (the Hon. Secretary) passed round some of Burroughs, Wellcome, & Co.'s ortol tablets for trial. There was a curious point about the proportions of the ingredients to which he wished to draw attention. The firm had for some time been working out the formula without his knowledge, and they also knew nothing about his own experiments until the publication of his recent article on the subject. He now had the formula of Burroughs, Wellcome, and himself compared in grains, and the similarity between them was remarkable. On a basis of 2 grains of ortol, the difference in the quantity of sodium carbonate was 0.2 in 16 grains. The sodium sulphite was

as 1 to 2, and the bromide as 4 to 1, but, as there was no hypo in the tabloid formula, the result was practically the same, for Mr. Welford had a small proportion of this slight intensifying agent.

Some prints of several colours upon Gravura paper were shown, some done by Mrs. Welford and black in tone, and others by Mr. Bartlett of a warmer colour.

Mr. A. MACKIE took the opportunity of criticising the custom with many paper-makers of supplying their goods in cut sizes and not in sheets. Large numbers of people had little or no use at all for fixed sizes, and it would be a great boon if they were enabled to buy in large sheets if they so wished.

The suggestion was thought to be one which would commend itself to the makers' attention.

The CHAIRMAN showed half-a-dozen lantern plates, nine years old, for comparison with what was thought the proper thing of the present day. The glass was of about double the thickness which is now the fashion, a generosity which would be now little appreciated.

Mr. MACKIE remarked that, while thin glass was desirable for plates of small dimensions, it was very risky for 12×10 or larger plates. He had used plates which positively bent in the hand.

#### PHOTOGRAPHIC CLUB.

DECEMBER 6.—Mr. A. Mackie in the chair.

Mr. F. A. BRIDGE remarked that, in Mr. Fall's recent lantern lecture upon animal photography, an observation was made that he could not use for his work backed plates, because the backing slowed the plates to a degree which he could not afford. It would be interesting to know whether this was also the experience of other members.

The CHAIRMAN thought that many people entertained the idea that backing slowed a plate, on the ground that the backing medium prevented the reflection of light from the back surface of the glass, which would otherwise help the exposure.

Mr. J. R. GOTZ said that, when a plate was backed by a white medium, it quickened the plate. The inverse would be that a dark backing would slow it. This was perhaps Mr. Fall's basis of argument.

Mr. HENRY E. HULL had proved that a white backing helped the exposure a little, although tending towards halation. However, it did what was often wanted. Practically it was a help, but theoretically it was not very likely.

Mr. BRIDGE was doubtful about the matter, and thought that, given decent conditions, backing could not possibly slow a plate.

Mr. BRIDGE showed two negatives on Secco film, which he had developed and stripped, and a discussion ensued as to the possibility of the grain showing in the resulting print or positive. A slide was subsequently made, but nothing aggressive was noticed. It will be shown on the screen, however, at a future meeting.

#### GRAVURA PAPER.

Mr. BALDWIN demonstrated, for the Paget Plate Company, the use of Gravura emulsion upon paper, opals, and lantern slides. Gravura specialities offer a means of printing which can be safely conducted in diffused gaslight. The emulsion is slow, but such as to give, by modification, a range of colour from blue-black, through all the intermediate tints, to red chalk. It may be had either glossy, matt, or rough, and the colours are obtained in every case by pure development. Being a slow emulsion, exposure is best effected by the combustion of magnesium ribbon, rather than the use of the ordinary gas jet, and its superior constancy furnishes additional reason for its employment. For black tones, half an inch of magnesium at fifteen inches or more will be suitable for a negative of medium density; for brown tones, six times this quantity; and for red tones eight times should be allowed. For black tones, the developer should be used in what is termed "concentrated" form. A diluted developer with a short exposure tends to give greenish-black tints, not the blue-black for which Gravura is noted. As one lengthens the exposure for warm tones, so also, proportionately, must one dilute the developer. Red, the extreme of the warm colours obtainable, requires the longest exposure, combined with the weakest developing solution. The developer recommended is a metol-hydroquinone combination:—

Hydroquinone .....	55 grains.
Metol .....	14 "
Sodium sulphite .....	1 ounce.
Sodium carbonate .....	1½ "
Potassium bromide .....	2 grains.
Water, to make .....	1 pint.

For the warm tones dilution of the above is necessary, as stated, the scale being as follows:—

Cool to warm sepias .....	1 ounce to 5 ounces water.
Warm brown to red .....	1 " " 7 " "
Red chalk .....	1 " " 19 " "

In each case an increasing proportion of the following solution is also required:—

Ammonium bromide .....	1 ounce.
Ammonium carbonate .....	1 "
Water, to make .....	1 pint.

The quantity varies from 50 minims to half an ounce, according to colour.

A number of prints and opals were made and passed round, and a hearty vote of thanks was accorded to Mr. Baldwin.

**Croydon Camera Club.**—There was a goodly company on Wednesday, the 13th inst., to hear and see all about a new and certainly remarkable film, the invention of a member of the Club, Mr. J. T. Sandell. All kinds of "supports" have been advocated and tried for spreading the sensitive gelatine emulsion upon, but so far without absolute satisfaction. The remarkable point about Mr. Sandell's film is that there is no support whatever. The film consists of nothing but the actual gelatine emulsion itself. A moment's

thought will convince that, if there are no counteracting defects or faults due to the above expedient, there must be an enormous gain in doing without the troublesome support. Amongst the advantages are that development, proceeding from both sides of the film at once, is more rapid. For the same reason, fixing and washing are done far more quickly than with a glass plate or a celluloid film. A curious, undesigned advantage which accompanies the Cristoid film, as it will be called, is that, in consequence of the expansion set up in the gelatine film during development, each negative is a size larger than when exposed. Thus a quarter-plate will, after development, measure about 5×4, while the latter size will become enlarged up to about half-plate—6½×4½. If desired, this enlargement may, however, be prevented by the use of spirits of wine. Not the least advantage of this wonderful film is its great latitude, which Mr. GRANT, who, in Mr. J. T. Sandell's unavoidable absence, undertook the lecture and demonstration, stated was equivalent to the difference between 1 and 800. In order to illustrate this, he developed films, one of which he stated had received 300 times the exposure of the other. The above, together with other films, were developed all together in one dish for a fixed time of six minutes. The shortest exposed film was, when fixed, apparently of admirable printing quality; the other film was, as anticipated, too dense for use in ordinary printing; but, after a short immersion, straight from the hypo, in an amber-coloured solution of ferrocyanide of potassium, the reduction in density which ensued transformed it into an equally satisfactory negative. This valuable latitude is due to the fact that the Cristoid film consists of the double emulsion employed for the Sandell plates. In this there are two adherent emulsions, one being very rapid, the other slow and thickly coated. The developer advocated is one of the newest that has lately come to the front, viz., pyrocatechin, which, as the PRESIDENT remarked, recent improvements in manufacture have made absolutely reliable in action and cheap in cost, while investigations have resulted in a more suitable accelerator being used than was at first advised, with the result that we now find in this reducing agent a clean, reliable, rapid, and density-giving reducer, which is, moreover, a one-solution developer.

**Polytechnic Photographic Society.**—Mr. SANDELL gave a demonstration on his new Cristoid film before the Polytechnic Photographic Society on the 6th inst. This film, which is just being placed on the market, possesses similar characteristics to his well-known Perfect plate, and consists of a double gelatine emulsion without any other support. Particular attention was given to the difficulties which beset hap-hazard workers, and remedies were suggested, the chief of which, the lecturer stated, was to adopt the use of one plate and one developer, ingeniously adding, preferably, the Sandell Perfect and its recommended developer.

**Richmond Camera Club.**—The meeting on the 4th inst. was devoted to a show of members' lantern slides. Slides were shown by Messrs. Cheese, Dale, Davis, Emery, Kilbey, Richardson, and Rodman. Those by Mr. Davis were experiments with the new Gravura plates, and showed the range of colour obtainable very well. The slides by Messrs. Cheese and Rodman were illustrative of a cycling tour in Germany and Austria last summer, and Mr. Kilbey showed some remarkable results obtained with a focal-plane shutter working at 1/100 second.

**Woodford Photographic Society.**—This Society held its Annual Exhibition at the Wilfrid Lawson Hall, on Thursday, Friday, and Saturday of last week. The Thursday was devoted to a "private view" and the opening ceremony; on the other two days it was open to the public. A number of members and their friends gathered together on Thursday to welcome Colonel Lockwood, M.P., who performed the opening ceremony; and, after he had been conducted round the screens, he ascended the stage, and, in a speech remarkable at once for literary charm and graceful delivery, congratulated the Society upon the excellency of the work shown. After a slight interval a number of slides were passed through the lantern. The arrangement for the display of the pictures, as well as the quality of the work on view, showed an advance upon previous years. Nearly all the principal members contributed, as well as many of the younger ones, and, considering that no external photographic work was shown, the Society's display was very creditable, both in regard to quantity and quality. Many of the pictures have been on view in London and elsewhere from time to time. Among the principal contributors may be mentioned Messrs. H. T. Malby, F.R.P.S.; H. W. Bennett, F.R.P.S.; H. Wilmer, F.R.P.S.; E. Marriage, F.R.P.S.; A. Horsley Hinton, J. T. Ashby, E. Noble, W. L. F. Wastell, F. G. Ember, &c. The lantern slides and transparencies were quite a feature of the show, and attracted a great deal of attention. On Friday Mr. E. J. WALL, F.R.P.S., attended and gave a lecture upon "Colour Photography." The attendance throughout the whole time the Exhibition was open was very satisfactory, and gave great encouragement to those who worked so hard to make it a success.

**Fakenham District Camera Club.**—December 4.—Mr. WALTER D. WELFORD, F.R.P.S., favoured the above-named Club with a visit, and in the evening delighted a numerous company of members and friends with his lantern lecture, entitled

#### A BELGIAN EXCURSION.

The lecture was illustrated by about 200 slides from negatives taken by twenty-two members of a party which, in August last, spent a very happy week in Belgium under the leadership of Messrs. W. F. Slater and W. D. Welford. For an hour and ten minutes Mr. Welford kept every one thoroughly interested and amused, and the end came only too quickly. The slides were of uniform excellence and attractive variety, comprising cathedral and other exteriors and interiors, street and market scenes, figure studies, and river and canal scenes in and about Brussels, Antwerp, Namur, Dinant, Malines, Bruges, and Waterloo. The animal and bird studies at the Antwerp Zoo, and several of the interiors and character studies were especially good.

**Liverpool Amateur Photographic Association.**—The weekly meeting of this Society was held at the rooms, Eberle-street. Mr. F. ANYON gave an interesting demonstration on

#### COMBINATION PRINTING: THE EVOLUTION OF A SNAP-SHOT.

Mr. J. H. Welsh (Vice-President) presided. Mr. ANYON dealt with his sub-

ject in an able manner, and by practical illustration showed the ways and means of producing an artistic result by the combination of a series of pictures, mostly snap-shots taken at various times. By the means of snap-shots taken in Scotland, Bootle, and the Isle of Wight, Mr. Anyon produced a beautiful specimen of photographic art. While on the subject of combination printing, he showed the audience how, by means of quarter-plate pictures of sky and foreground, he could produce a beautiful result of half-plate size. A vote of thanks was accorded the lecturer on the motion of Mr. A. TYRRE.

**Edinburgh Photographic Society.**—The third meeting of the session of the above Society was held last week in the hall, 38, Castle-street, Mr. A. Edington (President of the Society) in the chair.—There was a large attendance. Mr. J. B. READMAN, D.Sc., read a paper on "The Chemistry of Photography in Relation to Development," showing the action of light on the silver sensitizers used in the photographic plate, and the action of the developing solutions. Mr. Readman illustrated his remarks by chemical experiments, and at the close was heartily thanked.

### FORTHCOMING EXHIBITIONS.

1899.  
 December 15-18 ..... American Institute Photographic Salon (New York). Hon. Secretary for European Exhibitors, H. Snowden Ward, 6, Farringdon-avenue, E.C.  
 „ 15-Jan.1900 Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.  
 „ 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.  
 1900.  
 January 29-31..... Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.  
 February 10-24 .... Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.  
 March ..... South London Photographic Society.  
 April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

THE following applications for Patents were made between November 27 and December 2, 1899:—

- PHOTO-PLASTOGRAPHY.**—No. 23,640. "Process of Casting Photographic Plaster or other substances for the Production of Stereotypes, Pictures, Engravings, and the like, flat or raised, and for the Reproduction of Photographs." M. BERNSTEIN.  
**ANIMATED PHOTOGRAPHY.**—No. 23,679. "A New or Improved Method for Photographing and Exhibiting Moving Pictures." G. HOLLINGUM.  
**COLOUR PHOTOGRAPHY.**—No. 23,685. "Improvements in Apparatus for Producing or Exhibiting Colour Photographs." W. WHITE.  
**PROJECTION APPARATUS.**—No. 23,742. "Improvements in Magic Lanterns and similar Projecting Apparatus." D. A. LOWTHIME.  
**COLOUR CINEMATOGRAPHY.**—No. 23,863. "Improvements in Cinematographs for Taking and Projecting Photographs in Colours." W. N. L. DAVIDSON.  
**FILM COATING.**—No. 23,880. "Improvements in Apparatus for Coating Photographic Films and Plates with Sensitive Emulsions." C. E. HEARSON.  
**FILM-DRYING.**—No. 24,020. "Portable Stand for Quickly Drying Photographic Films or Plates." E. K. HOLMES.  
**CINEMATOGRAPHY.**—No. 21,039. "Improvements in Apparatus for Taking, Projecting, or Inspecting Series of Photographs." W. BRITAIN, JUN.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### STEREOSCOPIC PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Most human eyes are  $2\frac{1}{2}$  inches apart. As I have proved, a stereoscopic camera, whose lens centres are  $2\frac{1}{2}$  inches apart, gives ample

stereoscopic effect, absolutely without eye strain. Cameras with wider centres, therefore, give unnatural effects. There is much eye strain, which has probably much to do with the disuse of the instrument.

Small plates,  $5\frac{1}{2}$  by  $2\frac{1}{2}$  inches, would be cheap when the demand came. The camera with 4-inch lenses might be "fixed focus," or focussing, but any way would be as small as a  $\frac{1}{2}$ -plate hand camera—what an immense saving over the cumbersome things offered now. These huge boxes are again a powerful reason for leaving them at home. I should like to see you handle this subject, taking as text, " $2\frac{1}{2}$  inches must be right, as it is natural."—I am, yours, &c.,  
 OLD SUBSCRIBER.

[Our correspondent, who resides in a distant part of the world, has probably overlooked the fact that within the last year or two we have several times dealt with the subjects of hand cameras for stereoscopic work and the separation of lenses. The latter point formed the theme of an article in these pages so recently as September 22 last. In the main we agree with our correspondent's ideas, although a fixed separation of  $2\frac{1}{2}$  inches is wrong in practice. It suffices for objects near to the camera, but in landscape work, where it is sought to obtain relief in objects situated, perhaps, hundreds of feet away, a separation of  $2\frac{1}{2}$  inches is insufficient. We deal with the matter in our ALMANAC just published. Perhaps the most important matter in stereography is to see that in the prints or transparencies foreground objects are not separated more than  $2\frac{1}{2}$  or 3 inches. We possess hundreds of slides that transgress this rule, and, consequently, make it a matter of considerable difficulty to obtain the binocular effect.—EDS.]

### DR. VON ROHR'S THEORY AND HISTORY OF LENSES: AN APPRECIATION AND A PROTEST.

To the EDITORS.

SIR,—The high praise you accord to Dr. Von Rohr's recent publication in your review on the 24th ult. will be endorsed by every student of optics, and again, any one interested in the historical evolution of lenses must respect the great research involved in its compilation.

Although Dr. Von Rohr, as stated, is connected with the firm of Zeiss, of Jena, it is not difficult to discover that in the main he attacks the subject-matter in the true scientific spirit, but his departure from it in a few isolated instances makes this departure the more remarkable.

I am one of the few left who was intimately acquainted with the late J. H. Dallmeyer, and the contemporary history of his life and work. Dr. Von Rohr, as you say, denies to him great powers of originality; unfortunately Dr. Von Rohr does not stop here; he disfigures an otherwise dignified work by innuendoes of an uncharitable nature, that are both personal and incorrect, and are the more to be deplored, as that eminent optician and generous man thus referred to has been dead some sixteen years.

It is well known that a certain section of the press was hostile to J. H. Dallmeyer in his early work, while another was appreciative. Dr. Von Rohr has consulted but one side of contemporaneous history, but even from this source we could not have made certain of the innuendoes referred to. Where he obtained his information from, and his motive, if any, are subjects best known to Dr. Von Rohr himself.

I make this protest, not out of disrespect for Dr. Von Rohr's ability and honesty of purpose, as will be evident, but as a tribute of deep-seated respect for the kindest employer with whom I laboured in my early days, and also in sympathy with his son. I am certain that no matters of history could have been referred to Mr. T. R. Dallmeyer, which is astonishing, as this gentleman is still the head of the firm.

I have purposely avoided details; to translate these aspersions can serve no good end. Further, I may say that I have not one iota of interest in the commercial aspect of the photographic world; but, at the period at which I was connected with it, I am confident that no contemporary optician could deny the first rank to the late J. H. Dallmeyer for originality. To name but a few of his works that occur to my memory: I saw the launching of his patent portrait lens, the rapid rectilinear, the wide-angle rectilinear, and the wide-angle landscape lenses.

In conclusion, my object is not in any sense controversial—let the old controversies of thirty to forty years ago be investigated by those who are sufficiently interested to examine both sides—but to enter a strong protest, due to the memory of a man whose work still lives, and the influence of whose work will always live.—I am, yours, &c.,  
 195, Great Portland-street, W., December 6, 1899. WILLIAM CURRY.

### ACTINOMETERS.

To the EDITORS.

GENTLEMEN,—Two recent references seem to me to call for direct contradiction.

Mr. George Fernau in an article in your ever-welcome ALMANAC gives a series of tables for calculating enlargement exposures from actinometric observations which would, no doubt, be useful; but in his introduction he

asserts that "no instrument or mathematical calculation based upon it will permit of accurate reckoning the time of exposure required by day or artificial light for enlargements on bromide paper by means of a camera."

Now, for some years, the Watkins Standard Exposure Meter has been provided with the two scales for conjugate focus and density of negative, and an enlargement exposure can be calculated straight away on the slide rules at one calculation without reference to a single table. The scale is also extended for calculating exposures when copying, and the instrument is extensively used for both these purposes. It is a little amusing to see that Mr. Fernau copies the exact relative speeds of bromide papers, which are the result of my own tests, and are given on my speed card for use with the Watkins meter.

I am inclined to think that Mr. Ferrero is entitled to the credit of first calculating enlargement exposures with an actinometer. He worked out some tables for use at the Camera Club.

The second statement is in a summary on page 749 of the *BRITISH JOURNAL OF PHOTOGRAPHY* of a paper read by Mr. H. W. Bennett at the Royal Photographic Society.

"With regard to exposure, actinometers were of no practical value for interior work." As some readers may take this to be the consensus of expert opinion, I am bound to point out that the statement is contradicted by the fact that the actinometer is constantly used for interior work by scores of expert architectural photographers.

To give an instance: In 1897 the one medal for an architectural interior at Pall Mall was awarded to Mr. Harold Baker; in 1898 the medal for an architectural interior was taken by Mr. C. S. Baynton. Both these gentlemen are enthusiastic in their use of an actinometer for interiors, and used them for the medalled pictures. Mr. Bennett was an exhibitor of architectural subjects at both these exhibitions.—I am, yours, &c.,

ALFRED WATKINS.

Hereford, December 9, 1899.

#### PRINT-WASHERS.

To the EDITORS.

GENTLEMEN,—I can thoroughly corroborate what your correspondent, Mr. A. E. Stanley, says of Marion's sectional print-washer in your issue of December 1. I have had one in constant use for some time, and I find it the most convenient and perfect washer I have yet seen. It acts equally well for plates or prints, thoroughly washing them with a most economical expenditure of water and time, one hour's washing with this trough doing the work as thoroughly as three hours in the usual manner. It is a boon that I could not well dispense with now that I know it.—I am, yours, &c.,

A. M. MACDONA.

Halton, December 6, 1899.

#### ORTOL.

To the EDITORS.

GENTLEMEN,—I find no less than four letters in your columns on Ortol; but as I have no means of knowing to what extent they are merely weak attempts at humour, there does not appear much to pay attention to. If the letters signed "Jonathan Wideawake" and "Hendrich Salt" are attempted skits, they have not even the merit of cleverness. The latter gentleman should really learn German before he tries to write bad English. "C. E. F. N." and "Novice" do not appear to have troubled their wits very much. They both deem my formulae obscure, but, if they will turn back to page 711, they will find that I do not use the terms Solution No. 1 or Solution A at all, but I use the name of the chemical. It is very plainly and nicely printed in your paper. I will therefore ask "Novice" if he makes a solution of ortol, 1 ounce; metabisulphite,  $\frac{1}{2}$  ounce; and water, 60 ounces, how he is going to get 3 ounces of pure ortol out of it as he suggests? If he can, he will prove my argument that ortol is cheaper than pyro. Perhaps the bromide paper formula is not so clear as it might be, so I amend it to 1 ounce of ortol,  $\frac{1}{2}$  to  $\frac{3}{4}$  ounce of soda, 1 ounce of sulphite, 1 ounce of water, and 20 grains of bromide. The difference in the soda is  $\frac{1}{2}$  ounce for soft to  $\frac{3}{4}$  ounce for hard negatives. In all my writings I am not ashamed of my own name, and therefore decline to answer any more letters unless the writer feels the same way. Nor am I at all ashamed of my advocacy of ortol—the future will prove the truth of my assertions—and, if those who are endeavouring to make fun of me now will have the honesty later on to admit that I at least knew what I was writing about, then they can have as much fun as they like. The enormous interest taken in ortol of late, and the number of converts from pyro, very few would credit unless they were in my position.—I am, yours, &c.,

WALTER D. WELFORD.

To the EDITORS.

GENTLEMEN,—I am sure all your readers must be very much obliged to Herr Sapt for his supplementary figures to Mr. Welford's results.

My prejudices against the idea of the repeated use of a developing solution are being weakened by the prospect of being able next year,

perhaps, to do an entire year's work with "one lot of solution." But I am still in some doubt as to whether I may not have to add a little water from time to time during "die hottest days" so feelingly alluded to by mein herr Sapt; and, if this correspondent will tell us whether he added any water so as to get all his 9760 films wetted as well as developed with eight ounces of solution, it will save me and others some experimental work. Even if water has to be added for purposes of development, the only limit to the repeated use of the developing solution now seems to be the full maintenance of the Water Company's supply, which is sometimes a little short during "die hottest days." But, after all, no very large amount of water is wanted, so we ought to be all right for next year.—I am, yours, &c.,

S. HERBERT FRY.

12, South-villas, Camden-square, London, N.W.

#### ADDRESS OF A SCULPTOR.

To the EDITORS.

GENTLEMEN,—We should not forget our old friend Albert Toft of Manressa-road, Pimlico, who some years ago modelled the presentation bust of the President of the Royal Photographic Society, James Glaisher. It was an admirable likeness. He also produced a medallion, a copy of which graces the walls of my billiard-room. Mr. Toft has executed several commissions for me, which in every instance have given complete satisfaction. I need scarcely add Mr. Toft is a gold medallist, an exhibitor at the Royal Academy; his busts of W. E. Gladstone, Rowland Hill, and many others testify to his skill.—I am, yours, &c.,

A. L. HENDERSON.

Templestowe, Torquay.

To the EDITORS.

GENTLEMEN,—Enclosed is a mount from Mr. Forsyth of Finchley-road, N.W., who has lately supplied a memorial tablet erected in our parish church in memory of the late Canon Jeffreys, the tablet is of brown veined marble, moulded and ornamented with oak-leaf border and coats of arms with a circular profile portrait in white marble inserted, the portrait being composed from several photographs of the gentleman; the work is very satisfactory. Perhaps Mr. Forsyth could undertake the work that "W. D." mentions in your last issue. I do not happen to have a print by me of the tablet, but should be happy to send one to "W. D." if he would like one, as I have a good half-plate negative of it taken by magnesium ribbon, as daylight is so flat and weak where the tablet is placed. This is not a bogus affair such as Mr. Penlake writes of. The camera was raised on a level with the centre of the work.—I am, yours, &c.,

Highgate, Hawkhurst, December 7, 1899.

E. WILLIAMS.

[No doubt our correspondent is now sufficiently supplied with the addresses of sculptors who are prepared to execute work from photographs.—EDS.]

#### THE NEW OXYMAGNESIUM LIGHT.

To the EDITORS.

GENTLEMEN,—In the last two numbers of *THE BRITISH JOURNAL OF PHOTOGRAPHY* you make mention of a new method of artificial light for portraiture by Mr. Smith of the Platinotype Company.

Now, this system of burning magnesium ribbon in oxygen gas was introduced and, I believe, patented about fifteen years ago by Mr. McLellan of Glasgow, and a great number of the apparatus sold throughout the country by Mr. George Mason, who was agent for the invention.

The method for using the above was just the same as described in the *JOURNAL* with the exception that the magnesium was not lighted by electricity. Water was introduced into the oxygen globe, as Mr. McLellan found that the light was more steady when burned over water, also with a supply of air.

Enclosed is a rough sketch as near as I can remember of the old system. I have observed for upwards of forty years all the systems of artificial lighting for photography, and believe that the oxymagnesium is the most actinic light, and the best for taking instantaneous photographs.

Much praise to Mr. Smith for bringing the subject before the photographic profession.—I am, yours, &c.,

JOHN URIE.

9, Wood-street, Alexandra Park, Glasgow, December 5, 1899.

[We are much obliged to Mr. Urie for his letter and the sketch. The latter shows a gas-holder supporting a glass globe wherein the magnesium is burnt in oxygen. The principle of the system is, of course, not new, and in all applications of it to photographic purposes there must inevitably be some similarity of design; but in the Platinotype Company's apparatus there are many differences of detail as compared with the older forms, and, above all, the fact that the magnesium ribbon is electrically ignited.—EDS.]

## THE KODAK DIVIDEND.

To the Editors.

GENTLEMEN,—I have to inform you that the Directors have declared an interim dividend on the Company's Preference issue for the quarter ending December 31, 1899, at the rate of six per cent. per annum, and on the Ordinary shares at the rate of ten per cent. per annum for the same period, which dividends will be payable on or after the first proximo.

They have, further, resolved that the transfer books be closed from the 18th to the 31st inst., both days inclusive.—I am, yours, &c.,

T. HALLETT FRY, Assistant Secretary.

43, Clerkenwell-road, London, E.C., December 12, 1899.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

## PHOTOGRAPHS REGISTERED:—

E. Ball, 30, Edward-street, Stockport.—Photograph of Colonel Wilkinson.

G. Denney, 1, Cary-parade, Torquay.—Photograph of E. F. Knight, war correspondent, "Morning Post."

\* A. T. DEANE.—A matter in which we cannot be of assistance, as it is against our rule to recommend one maker's goods in preference to those of another.

\* CHRISTMAS AND NEW-YEAR'S MOUNTS.—W. WAIN. Refer to the Advertisement columns for the last month or two, and you will find where you can get what you require. We do not recommend any particular maker's goods, whether mounts or anything else. It is quite against our rule to do so.

\* STAINED BROMIDE ENLARGEMENT.—W. W. N. If the stains came out within a month of your receiving the enlargement, it is clear that it was carelessly produced, and the enlarger must supply another free of charge or refund the money, which may be recovered in the County Court. We are surprised that any one should demur to replace a picture under such circumstances, even for his credit's sake.

\* INK STAINS ON NEGATIVES.—W. A. WHITING says: "Could you kindly suggest, in your Answers column, a safe remedy for removing ink stains?"—Without knowing the composition of the ink we cannot offer a suggestion. What would remove one kind would not remove another. If the stain cannot be got rid of by washing, the best way will be, as it is in the hair, to touch it out in the prints. Tampering with the negative may lead to its ruin.

\* WINTER PORTRAITS.—J. AND R. write: "Would you advise us as a business matter to make a feature of winter portraits—that is, portraits with wintry surroundings, like some we have seen from Canada and the States?"—Yes, if we are going to have a "good old-fashioned winter," then it might prove very remunerative. But, as we do not know what sort of winter we shall have, we cannot advise further. However, it may be well to be prepared with specimens and suitable accessories on the chance.

\* TITLES OF PROCESSES IN FRANCE.—AJAX says: "Can you tell me what is the process called 'Phototypie' used in France (and perhaps also in Germany)? Is it a modification of collotype? There are numberless processes for producing book illustrations—or rather names given to processes of reproductions—but I suppose they are all much the same. The German 'Lichtdruck,' for example, is, I suppose, a collotype of some sort."—In reply: By phototypie the half-tone engraving process is probably meant.

\* TRANSFERRING COLLODION POSITIVES.—POSITIVE says: "Will you kindly inform me how to transfer the film of a wet-plate positive (from the glass plate) to a metal surface. Is there any special collodion used?"—Simply immerse the positive in a dish of water to which a few drops per ounce of hydrofluoric acid have been added. In a few minutes the film will leave the glass and may be floated on to anything that may be required. It may be well to give the metal a thin coating of gelatine, allowing it to set, before floating the film on to it. It is advisable to use a rather thick and rough collodion.

\* COPPER PROCESS.—FINCHLEY says: "Customer orders a picture on copper, from negative of sitter. Can you suggest what process is required? On copper, not printed from copper."—If a print, simply, is wanted on the metal, it can easily be produced by the carbon process in the ordinary way; but the picture will be reversed, as regards right and left, unless printed from a reversed negative. It may, however, be made by the double transfer method, developed on flexible support, and then transferred to the metal. In this case the copper must have a substratum of gelatine to which a little chrome alum has been added.

WANT OF DENSITY IN NEGATIVES.—N. CONWAY writes: "I am now completing the development of a lot of negatives I took on my holiday in the autumn. I developed some a few weeks ago, but business prevented my doing the remainder at that time. Now I find that the image comes out very slowly and I cannot get sufficient density. Is this due to the long keeping or what, as I am using the same developer?"—It is probably due to the lower temperature we have now. Warm the dark room up to 65° or 70°, and use the solutions at the same temperature, and we have small doubt all will go well.

IRON DEVELOPER.—T. BATEMAN says: "I have bought a fresh lot of sulphate of iron, and made up a solution of it of the same strength I always make it for developing bromides. It seemed all right at first, but on standing for a day or two, a lot of the iron falls to the bottom of the Winchester, and the solution is so much the weaker. I got some more from another shop, and that has gone the same. What is the reason, as it has never done so before?"—The reason is that the solution, when made, is nearly or quite saturated with the salt, and cold has caused it to crystallise out. The remedy is, not to expose the solution to a low temperature after it is made.

SPOILT DAGUERRETYPE.—W. R. writes: "I had a Daguerreotype portrait, which is highly prized by its owner, brought to me to copy. It was very much tarnished, and I tried cleaning it round the edge with rouge on soft wash leather and it came off easily. Then I went over the whole picture with it and got off all the tarnish, but there is only a very faint trace of the portrait now. Please tell me in your next how to restore it, as it belongs to one of my best customers!"—We cannot nor can any one else. In clearing off the tarnish in the way you have done, you have cleaned off the image, and there is no known method of restoring it. The picture is irretrievably ruined.

STEREOSCOPIC PHOTOGRAPHY.—H. G. DOGGETT says: "In your most valuable article on Stereoscopic Photography in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1900, you refer on p. 674 to a form of stereoscope 'peculiarly suited for transparent photographs.' That particular form of photograph is my special hobby, and I should esteem it a great favour if you would be so kind as to tell me where I could obtain such a stereoscope as is indicated in the passage quoted."—In reply: The context of our article will show that the form of stereoscope referred to (a combination of mirror, prism, and lenses) was suggested by Sir Howard Grubb. So far as we are aware, it is not on the market.

PRESERVATIVE SOLUTION FOR P.O.P.—D. HALL says: "Some time ago (say three years) you published a solution—I believe it is called lemon solution for preserving prints, that were available for, say, a month or so—which I think would now be useful to me, as I occasionally have to print one copy, which makes it rather expensive for gold toning. Could I therefore so far trespass on your good nature as to ask you to oblige me with a formula?"—We cannot call the formula to mind, and the data, "say three years ago," is too vague upon which to start a search. It is not a very costly matter to make up just sufficient solution to tone a print as occasion requires, seeing that a couple of grains of chloride of gold or less is sufficient to tone a full sheet of paper.

HYPO IN THE DEVELOPER.—C. W. says: "Mr. Walter D. Welford, in his article on ortol as a developer, which ends in the last number of your JOURNAL, says: 'The use of a minute portion of hypo is a decided advantage. The action of the hypo solution is rather curious. Half the quantity appears to act just as well, and a little more does no good, whilst too much merely gives fog.' He also tells one that for developing bromide prints he does not think that the minute quantity of hypo would do harm, but rather recommends its being left out. He nowhere says what the action of the hypo is. Can you tell me?"—The hypo is said to act as an accelerator, but we ourselves have not tried it with ortol. Indeed, we never use it in a developer in our own practice.

ORTHOCHROMATIC PHOTOGRAPHY.—F. J. P. says: "I shall be very grateful if you can give me a little advice as to the use of isochromatic plates. Can you recommend me the best brand of isochromatic plates, and if a longer or shorter exposure is required when using the screen? Would these plates be the best for taking snow and mountain scenery, and, if so, would they be equally suitable for short exposure, such as street scenes, &c., and general landscape?"—It is strictly against our rule to recommend any particular maker's goods. Better get samples of the different brands on the market, and see which answers best in your hands. A longer exposure is necessary with a screen, the time depending on the depth of the colour. The plates will do quite well for ordinary work, without the screen. If the light is yellow, an advantage will be found in orthochromatic plates for snow scenes, &c.

STAINS ON PRINTS.—STAINS says: "I should feel obliged if you will kindly explain the cause of the stains on enclosed print. It is not till after mounting and burnishing that they appear, and in some cases the prints have got out to customers and been returned owing to their being like sample. I have not long been started in business, and have not had much experience in printing, having been operator and retoucher only. At first I thought it might be owing to using a dish in which a diluted solution of acid for platinum prints had been used, and in consequence I got a new set of dishes. The toning bath is the formula recommended for Barnet P.O.P., which paper I use. I might add that the fixing is done in a different room to that in which toning is done. My assistant washes the prints and fixes them, and I do toning. Since taking these precautions the stain has not appeared so far."—The stains on the prints sent are due to imperfect fixation where they are. The prints have been allowed to stick together while in the fixing solution, so that it has not had free action all over the print.

## A GREETING.

It is our happy privilege to possess the personal friendship or acquaintance of thousands of the readers of this JOURNAL and its ALMANAC in all parts of the world. To these, as well as to the larger number who must of necessity only know us by the medium of print, we venture to send the heartiest greetings of the season. Though the nation is at war, the arts of peace still pursue the paths of progress, and it is with the most earnest hope for the prosperity of photography that we wish all interested in it

A MERRY CHRISTMAS AND A HAPPY NEW YEAR.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC  
FOR 1900.

EDITED BY THOMAS BEDDING, F.R.P.S.

What some readers think of the book:—

- "Even better than its predecessors."
- "A remarkable publication."
- "Full of valuable information."
- "Useful and portly."

- "A lot of it—looks all right."
- "Ever welcome."
- "Most interesting and instructive."
- "I cannot understand how, in such a short time, you can complete such a stupendous work."
- "Much to enjoy in the present ALMANAC."
- "I daily enjoy the admirable ALMANAC."
- "I see several new features, whilst retaining the general familiar appearance, which if much altered would give the impression of another book. Good old friends are best kept."
- "The most wonderful publication for a shilling that I have ever seen. You deserve all the praise words can afford for so useful a work."
- "The ALMANAC is the best thing of its kind."
- "A work of monumental capacity."

## A few opinions of the Press:—

- "Well up to date. . . . an indispensable adjunct to the outfit of the photographer." *Morning Advertiser.*
- "Welcomed by thousands of photographers, trade and amateur, who have come to regard it as indispensable." *Newcastle Daily Journal.*
- "Welcome both to professional and amateur photographers." *Manchester Guardian.*
- "No photographer ought to be without it." *Shrewsbury Chronicle.*
- "Almost a reference library in itself." *British and Colonial Druggist.*
- "A work of which specialists have long known the value." *Glasgow Weekly Herald.*
- "A useful volume which no photographer should be without." *Kent Argus.*
- "Crammed full of all the very latest information." *Invention.*
- "A massive and remarkably cheap volume." *Birmingham Daily Gazette.*
- "There is nothing like it in the photographic world that we know of, either for bulk, or variety, or merit." *Western Mail.*
- "A very bulky volume at a very moderate price." *Gloucester Journal.*
- "The whole book is thoroughly practical." *Horse and Hound.*

\* \* The 1899 Edition of the Almanac (20,500 copies) was entirely exhausted within three months of publication—a fact without precedent in the history of photographic publications.

\* \* Of the 1900 Edition just issued nearly 17,000 copies were disposed of on the day of publication: an increase of between two and three thousand as compared with last year. It is probable that the entire edition will be out of print within a few weeks from date.

## EX CATHEDRÂ.

M. "TANQUEREY," of the Société Artistique de Portraits, Paris, undeterred by the searching attentions of the English press, is still engaged in widely distributing his free-portrait circulars in this country. Several batches of his literature have recently been sent us by correspondents. We append a copy of M. Tanquerey's "third advice," which is evidently sent to those people whom he finds a difficulty in persuading to buy one of his frames: "We beg to remind you, for the third and last time, that we are still without your instructions concerning your life-size crayon portrait, now finished for a long time. If you could only be here in our studio, and see the magnificent specimen we have turned out for you, you would not hesitate a minute in remitting us the eight shillings we have already asked you to pay for the necessary boxing, packing, and carriage expenses from Paris to your home. A crayon drawing cannot be compared with a chromo or a lithograph, it cannot be rolled up and sent by mail; on the contrary, in order to secure its safe arrival and prevent it from being scratched or rubbed, it must be carefully wrapped and boxed, when it is forwarded by the Express Company, who have a branch office in Paris. All this runs into expenses, which have to be paid in advance. We are sure that you do not expect us to defray these expenses for you in addition to making you a crayon portrait of nearly 18 x 22 inches large entirely free of charge. We know you to be perfectly fair, and that you will do what is right in this instance."

\* \* \*

BUT it is plain that 18 x 12 bromide enlargements (which are reputed to be made in this country) bear a handsome profit at eight shillings each, for M. "Tanquerey" is willing to take half that sum for them—if he can get it. Thus: "As we desire to close this matter at once, we make you the following offer, good for thirty days from date: Send us four shillings, for which amount we will forward you your crayon portrait carefully packed and boxed, and, if our work is to your satisfaction, you will please remit the balance of four shillings to our carriers. Should we be without an answer to the present communication within thirty days, we will take it for granted that neither your portrait nor your photograph are of any interest to you, in which case, and after said date, we will no more be responsible for either of them. Should you decide to send us the full amount of eight shillings at once with your order, we will make you a present of a splendid detective camera, which takes pictures  $4\frac{1}{2} \times 6$ , and deliver free of all charges to your home." We make M. "Tanquerey" the suggestion that, as the expense of communicating with his English clients and boxing and wrapping up his "magnificent specimens" is so great, he should open a branch in London. Then his clients would be saved the time, trouble, and expense of going to Paris to see these specimens and the splendid detective camera which he gives away as presents.

\* \* \*

LAST week Mr. Alfred Waterhouse, R.A., presided over a meeting to consider the past progress and future methods of "Scapa," as the Society for Checking the Abuses of Public Advertising is familiarly known to its adherents. Mr. Waterhouse deplored the conduct of advertisers who enrich themselves by defacement of this beautiful world, and he would appeal to all to bring their private conduct into a line with

their ideals, and to taboo the soap, pills, or what-not of those whose advertisements were an abuse of taste or manners. An encouraging report was submitted by the Hon. Secretary (Mr. Richardson Evans), who looked to municipal authorities for the chief abatement of the nuisance, whether it takes the form of disfiguring fields, forests, hill tops, or house fronts. The public opinion, created in large measure by the Society, had at last enabled Edinburgh this year to get Parliament to extend its powers in this direction, and the success of its appeal had encouraged several other municipal bodies to add clauses to their private Bills extending their powers over open-air advertisements.

\* \* \*

WE understand that the Eastman Kodak Company, of Rochester, N.Y., are supplying the American photographic public with daylight cartridges for Kodak work, containing rollable film for two or six exposures. This departure has been made to meet the requirements of the photographer who may wish to make a few exposures without using up an entire spool of a dozen exposures before resorting to development. It may be supposed that this new convenience in film photography will in due course be placed at the disposal of European photographers. In the States a cartridge containing sufficient film for six  $3\frac{1}{2} \times 3\frac{1}{2}$  exposures is retailed for thirty cents, or two cartridges, each containing two exposures = four exposures, may be had for twenty-five cents.

\* \* \*

SOME idea of the great use made of photography by the United States in the late war with Spain may be gleaned from the fact that, in reply to a circular sent out from the United States War Office to officers and men carrying cameras during the war, there have been received over 500 negatives and 300 prints of Porto Rican subjects, over 700 negatives and nearly 400 prints of Cuban and reserve camp subjects, and nearly 150 negatives of Philippine subjects, from which something like 350 Porto Rican, nearly 500 Cuban and a few Philippine subjects have been chosen to make the final selection for an album, and these negatives and prints were then returned to their owners. There are still on hand from which to make further selections over 200 Porto Rican negatives, 350 negatives and nearly 700 prints of Cuban and reserve camp subjects, and over 600 Philippine prints.

\* \* \*

IT is stated that "the work so far has been to make selections from the negatives and prints sent in, which are usually very small. The ones selected are then enlarged to the size of eleven by fourteen inches. After having been collected and enlarged, it is the intention to retouch these enlargements, and then make negatives from them for the purpose of making the final pictures. This is necessary on account of the small size of the negatives and prints received, and on account of the poor quality of most of them, as they had been taken under disadvantageous circumstances, often by persons inexperienced in the handling of their cameras. After as much material as can be obtained has been got together, the final compilation will be made. This work is regarded of importance, having already served to determine disputed questions. It is thought that in time the collection will be of such value as to induce Congress to publish it for distribution to libraries throughout the country."

No class of persons is so largely photographed as actors and actresses, and it is commonly believed that the desire to possess their photographs is so keen amongst innumerable members of the public that the footlight favourites are constantly being asked for copies. Our contemporary, the *Stage*, makes an excellent suggestion in connexion with the matter. It tells us that the well-known actor, Mr. Wilson Barrett, for a long time now, has always been willing to give his photograph or autograph to any one desirous of it on one condition, that the recipient should contribute something to the Actors' Orphanage Fund.

\* \* \*

"It is a good and generous action of Mr. Barrett, and we wish that all actors and actresses would do likewise. When the list of donations to the Actors' Orphanage Fund is published later on, you will find that the money given through Mr. Barrett for his photograph or his autograph." Our contemporary adds, that readers of the *Stage* in the provinces constantly are writing and asking where they may purchase photographs of certain favourite artists. Its advice is, Write to the artists direct, and suggest that the 5s., 10s., or 20s. sent with the letter for a photograph should, in accordance with Mr. Barrett's plan, be given to the A.O.F. And it adds that, if those pretty and fascinating ladies, whose photographs are to be seen by the hundred all over London, were to follow Mr. Barrett's lead, they would do much good to the Fund, and through it to the children of their late comrades in art. Come now, ladies and gentlemen of the profession, says the *Stage*, why not commence the New Year with the settled determination that, when your photograph is asked for, you will give it only on the condition that you receive money for it—money which you afterwards hand over to the secretary of the A.O.F.?

\* \* \*

We may remark that it is commonly supposed that actors and actresses do not pay for their photographs. This is an error, so that there is an additional reason why they should not be expected to give them away for nothing. Of course, the more the Actors' Orphanage Fund benefits by the sale of artists' photographs, the more profit will accrue to photographers (a not wholly undeserving class, we may remind the members of the theatrical profession), so that we hope our contemporary's suggestions will be largely availed of.

#### "PYRO" AS A DEVELOPER IN COLD WATER.

BE it by a kind of instinct or an intuitive sense of the fitness of things, whatever the cause indeed, the professional photographer generally blunders into, or stumbles upon, the right thing at the right time when that time arrives for a move forward. We say stumbles upon advisedly, for it must be admitted that few of those whose business in life is the utilisation of photography for portraiture or landscape give much time to experimenting, and of those few a still smaller proportion to exact experimenting; yet, as we say, they generally, to use a favourite scientific argot, seize the psychological moment when it arrives. The history of practical photography shows how the once-despised amateur did the laborious work of the laboratory and the professional walked in and took possession, and very often without the usual formula of acknowledging thanks.

Let us hark back to facts within the memory of many of our

readers. Time was when every one used iodised collodion and pyro developer. Within a brief period it was abandoned, and "bromo-iodised" collodion took its place, to be quickly followed by the abandonment of pyro for iron as the main developer. Equally sudden, when once started, was the change from the combined toning and fixing to the alkaline toning with a separate bath. At this time almost every one used Saxe paper. A well-known contributor once told us that when, after trying every kind of paper in the market and finding Rives infinitely superior to any, he, when placing his orders, was simply laughed at by his friends the makers, who said, "Nobody ever uses Rives." Yet who ever even hears of Saxe nowadays?

Coming to a later period, when emulsion photography and alkaline developer was devised, at a time when every portrait photographer and most landscape photographers in the land may be said to have used wet collodion, the same mysterious instinct gave warning that the moment had arrived, and with great dispatch baths were cast aside, and bottles of limpid collodion allowed to dry up into masses of horn. Oxalate of iron became the chosen developer; yet, before the novelty of the radical change of procedure from wet to dry had worn off, a wave of change passed over the land; iron developers were abandoned, and in virtually every dark room the developer was "pyro," and it has remained the favourite every since—at any rate, up to a very recent date. Excursions in the region of metal have been made, but few so far have taken to its general use, and some have announced their abandonment of it. It is not our purpose at the present time to say which is the developing agent we consider deserves the preference; we merely tabulate a few facts, and we abstain from self-laudation for the position in the van of progress that this JOURNAL has taken, as evidenced in the early days of gelatino-bromide.

Let us look at another aspect governing the choice of a developer, one, strange to say, that, all-important though it is, has held practically no position in the discussions upon the subject—we allude to the cost of the various developing agents. We are not aware that, apart from the question of using the same lot of developer for a succession of plates, any one has claimed that, weight for weight per ounce of water, any of the more modern developers will bring up the negative to sufficient density sooner than pyro; or, in other words, that an ounce of any one of them will make more quarts of developer of suitable working strength than would pyro.

That being the case, let us look at the price. What developing material, except pyro and hydroquinone, can be bought for a shilling an ounce, at which price these two are cheerfully sold? That is a dominant consideration, and exercises, perhaps unfelt, a dominant influence in keeping pyro at the top.

Hydroquinone at one time threatened to oust it, but, except among amateurs, the progress it once made has been arrested, and it has fallen back again in repute. The chief reason for its preference by amateurs is the fact that it does not stain the fingers anything like so readily as pyro, and this is an important consideration to those not professionally engaged in photography. The latter, as a rule, have always ignored any such fad as caring for stains—witness the "hands" we used to see in the "good old wet-collodion days." But is the use of pyro necessarily attended with stained fingers? We say no. We are about to give our readers a valuable tip: when dry fingers are dipped into any liquid, they quickly absorb, as it were, a portion of it, and it is very difficult to entirely free them from that absorbed liquid. So with pyro. But the bane

suggests its own antidote. Let the fingers before touching the developing solution be saturated with water by dipping them in it, and it will be found that, if every now and then they are again wetted with water, while occasionally fingering the plate in the developing solution, the stain will be reduced to a negligible minimum.

We will conclude by referring to one property of pyro often incidentally alluded to, but not yet to our knowledge exactly estimated, its amenability to the influence of temperature changes. We have heard from a contributor who has a series of experiments on this point in progress; and he estimates, subject to correction after further experiments, from indications already tabulated, that, after 55° F., a change of temperature in the direction of reduction needs an increase of five per cent. of the time needed at 60° for each single degree of temperature reduction! Our own experiments tend to confirm his estimate. Here is the key to a vast number of failures of "insufficient exposures," of "weak exposures," and so forth. The importance of this subject has not hitherto been grasped; but, contenting ourselves now with strongly calling attention to it, we must bring our article to a close with the promise that any more exact data obtained shall be brought forward in these pages as soon as available.

**Gold in Sea Water.**—We had thought that the last had been heard of the old fable of gold in payable quantity in the waters of the sea; but it seems that there still remain some believers in it, judging by the quest made by one of the *Daily Mail* reporters. Of course, we all know that there is gold in sea water; it is not many months since we published particulars of a thoroughly scientific examination of such water from various sources, but the quantity was so small as to render it an impracticable task to extract it without costing more than the product was worth. A reduction in the price of chloride of gold will not be brought about by auriferous oceans. The reporter referred to went down to Brighton, brought home a few gallons of ocean, and set to work to precipitate the gold therefrom by means of some wonderful preparation, the nature of which he was not allowed to divulge, but the name of which any of our readers used to residue-collecting could readily guess. He dumped into his few gallons of ocean two or three pounds, instead of an ounce, of his secret chemical, and obtained nearly a gallon of "sludge." This he took to an assayer of repute, who found it to contain '0031 of a grain of gold! If he had taken a thousand or two gallons of the water at Brighton, he would, at this rate, have obtained the munificent sum of twopence for the gold therein! He considers it is too early to express an opinion as to whether a projected company or syndicate could make by dividends by robbing the sea of its gold at this rate. Very possibly they may extract gold, but it would be from shareholders' pockets and not from the waters of the sea.

**Supposed Daylight Meteors.**—Last week we gave an abstract of some letters from Wiltshire and elsewhere which had been published through Professor Storey Maskelyne in *Nature*, the writers having described some star showers they had seen in broad daylight. In the current number of that periodical Mr. W. F. Denning pulls the accounts to pieces, and shows that the effects seen were not objective phenomena at all, but merely ocular illusions that could at any time be observed by any one looking intently at the bright sky for a few minutes. Mr. Denning writes: "It is astonishing that, if one calls the attention of people to imaginary phenomena of this kind, and asks them to look, they will, in ninety-nine cases out of one hundred, see the same thing and encourage similarly mistaken ideas. Yet, if we observe an unequivocal object, it is often very difficult to make others perceive it, and comprehend its character and the nature of the observation."

**A New Use for Röntgen-ray Photography.**—In a paper lately read before the Royal Society by Messrs. O. T. Heycock, F.R.S., and F. H. Neville, F.R.S., they described a method of making photographs of sections of particular alloys of gold they were experimenting upon. It consisted in using Röntgen rays instead of taking a negative by reflected light. The negatives so obtained were enlarged, and, say the writers, "the contrast between the Röntgen-ray photograph and the surface photograph of the same alloy shows what a much better picture of the structure of the alloy is given by the Röntgen rays."

**Novel Method of Thawing Frozen Water Pipes.**—The present is a very critical time for dark-room and printing-room operations. Every one is making strenuous efforts to get his negatives and prints through in time for Christmas; but it is an exceedingly well-contrived and organized place that is not interfered with by a long-continued and severe frost, which stops the water supply and arrests all printing work. Hence the plans described in *Science Abstracts* as being in successful operation in Canada will be of great interest. Alternating currents of electricity are passed through the frozen pipes, and usually, in a few minutes, the ice is thawed and water flows quickly through the pipes. A pressure of ten to fifty volts is used, obtained from a portable transformer connected with the street mains. A current of 200 to 300 ampères is passed through and the required effect is produced. Such a plan, if there are practical means of introducing the current, should, if it proved to be uniformly successful, be invaluable, for it often happens that the structural condition of a building in connexion with the water supply does not permit of the adoption of the obvious precaution of placing the pipes where the cold cannot find its way to them.

It must not, however, be forgotten that the stoppage of the water supply is not the only evil effect from frozen pipes, and when the water freezes it expands with such force as usually to split the pipe, and thus lead to leaks and floodings when the frost goes and the ice in the pipe melts, this, of course, being the explanation of the popular idea that it is the thaw that bursts the pipes. We have described from time to time many of the methods published or patented for preventing this bursting, but we doubt whether any are equal to Professor Apjohn's old contrivance for so preventing it. His plan was to solder into the exposed parts of the pipe at intervals (the shorter the better) short lengths of lead pipe closed at one end and open at the other. The water being turned off, these open ends are soldered against apertures in the supply pipe, and then offer a cushion of air for the expanding water to press against. The pressure is thus relieved, and, though ice is formed, its tremendous pushing or bursting power is prevented from acting, as it expends its energy in compressing the air in the chamber formed by the lead tube. The only thing that could militate against success would be the placing of the projecting tubes we are describing at so great a distance from one another that occasions might arise when the freezing water would, in two separate spots, shoot across the tube before the whole tube was frozen. The water would then be confined between these two ice barriers, and the "bursting charge" of frost have free play.

#### PHOTOGRAPHIC COPYRIGHT—AN APPEAL TO THE PHOTOGRAPHIC SOCIETIES OF THE UNITED KINGDOM.

We have much pleasure in giving publicity to the annexed appeal, which the Photographic Copyright Union is making to the photographic societies of the United Kingdom for their support in opposition to Lord Monks-well's Copyright (Artistic) Bill, which will probably be reintroduced to the House of Lords next session. We have already drawn attention to the fact on several occasions during the past year that that Bill proposes to substitute for the present Copyright Act of 1862, which has been found to work exceedingly well in the interests of photographic copyright, a measure alike unjust and spoliative in its provisions, and calculated to do serious harm to the photographic profession, as well as to amateur photography. We trust that the appeal for support now issued by the

Union will meet with a unanimous response from all the societies, so that the existing Act, in so far as it concerns photography, will not be interfered with by the Legislature.

### PHOTOGRAPHIC COPYRIGHT UNION.

*Affiliated with the London Chamber of Commerce (Incorporated).*

LONDON CHAMBER OF COMMERCE, BOTOLPH HOUSE, EASTCHEAP, E.C.

14th December, 1899.

The Committee of the Photographic Copyright Union invite the support (not necessarily financial) of the Photographic Societies of Great Britain and Ireland to oppose Lord Monkwell's Copyright (Artistic) Bill, which Bill will soon be for the second time before a Committee of the House of Lords. The enclosed petition draws attention to two important points which in our opinion every one who practises photography, whether as an amateur or as a professional, should strongly oppose. The drafting of this Bill has been prepared and printed without consultation with any Photographic Society or photographer. Therefore it behoves every Society to examine with careful attention its various clauses. Major-General Waterhouse, on behalf of the Royal Photographic Society and the Solicitor and Committee of the Photographic Copyright Union have already, before the Select Committee of the House of Lords to whom this Bill has been referred, offered evidence against it, and strongly protested against its passing into law.

The Committee of the Photographic Copyright Union appeal for support to all Photographic Societies to assist in strengthening their opposition on the reintroduction of the Bill next Session. In the present Act of 1862 the very production of a photograph made without valuable consideration enjoys Copyright, whereas in the proposed Bill no Copyright can be had unless the subject be registered within six months after date of production. Considering the enormous number of negatives taken by photographers, this compulsory registration is manifestly a great injustice.

To show how this would work out, one of our members informs us that a sitter to whom he gave a complimentary sitting some years ago, but did not think then that the portrait was of sufficient importance to register, has now become a world-wide celebrity, and his portraits consequently are of great value. Had the proposed new Bill been in force, this valuable copyright would have been entirely lost, but, by simply registering under the provisions of the Act of 1862, the entire rights and profits of the copyright are still reserved to the photographer.

It is extraordinary how little the artists have recognised the value of photography in a commercial sense. No consideration has apparently been given to the fact that the financial interests of photography are vastly greater than that of all the painters and sculptors of the country. It is therefore thought desirable that every photographer, amateur or professional, should protest against the exclusion of their valuable interests and the depreciation of their status.

We therefore beg that your Society may see fit to send us their written protest against the passing of this Bill until due consideration has been given to the interests of photographers. We suggest that the President and Secretary be authorised on behalf of your Society to sign the accompanying protest.

For the Committee,  
HENRY GOWER,  
Secretary.

[FORM OF PROTEST]

We, the members of the \_\_\_\_\_ Society, respectfully approach the Select Committee of your Lordships' Right Honourable House on the Artistic Copyright Bill, and beg to submit to your Lordships our protest against this proposed Bill.

We consider that by expelling Photography from the Fine Arts, in which it has always been classed since the Act of 1862, a slur is cast on Photography which is quite unaccountable, seeing that Photography is now of far greater importance than in 1862, and has, since that time, made marked advance in Artistic qualities in all classes of Photographs, Portraiture, Landscape, and Composition.

We also consider that Clause 16, making it compulsory, in order to secure Copyright, that every photograph must be registered within six months, failing which the Copyright is to be void, would be a very great hardship to Photographers. To carry out the conditions of this Clause would entail a very heavy tax, because millions of photographs are produced every year. We therefore respectfully suggest that the conditions as to Copyright and Registration of Photographs shall remain the same as in the Act of 1862.

There are various other objections to this Bill, but these two points, Classification and Registration, are those to which we most strongly object.

(Signed) \_\_\_\_\_ Chairman.

(Signed) \_\_\_\_\_ Secretary.

Date.....

### FOREIGN NEWS AND NOTES.

**Pyro Development.**—In Dr. R. E. Liesegang's paper, *Der Amateur Photograph*, an article is published concerning pyro development which is well worth consideration. After pointing out that pyrogallic acid was the favourite developer with the wet-plate photographer, and was followed by ferrous oxalate, hydroquinone, eikonogen, and the aniline derivatives, the writer alludes to the fact that photographers are returning to pyro, and that this tendency cannot be due to pure conservatism. R. E. Liesegang has often referred to the compound nature of the image formed by pyro development, the negative being composed of metallic silver *plus* stain. This almost eliminates the risk of over-exposure. On the other hand, pyro is recommended by manufacturers of shutters as the best developer for instantaneous work. These two extremes suggest that pyro is probably the developer giving most latitude. The writer of the article recently photographed a fresco painting, and gave four days' exposure at  $f/32$  with a deep orange screen. The light was good. A window, glazed with ground glass, was in the field of view, but, notwithstanding this was immensely over-exposed, a good negative was obtained, the window being as truly rendered as the fresco painting. An old oxidised pyro developer, with which six other plates had been developed, was used. In cases of over-exposure, a stale developer is recommended. Bromide of potassium merely retards, but stale pyro corrects. The following question was recently asked by Dr. Seitz, "Should development be adjusted to exposure, or exposure adjusted to development?" The writer answers: "In studio work, where the exposure can be accurately timed, the latter should be made to correspond with the developer, which should be very energetic. By such means the exposure may be reduced, and time saved in development. In work, however, where violent contrasts of light and shade exist, the development must be modified and suited to the exposure."

**Mercuric Intensification.**—In the *Photographische Mittheilungen* Dr. E. Vogel discusses the question, How long should plates be washed when subjected to mercuric intensification? It is usual to recommend very thorough washing when this process is undertaken in order to avoid subsequent deterioration of the negative through yellow stains. Dr. Vogel holds that these stains may be traced to imperfect fixing, and that, if this process is thoroughly carried out, five to six minutes' washing in running water prior to the mercury bath is ample, unless the plates have extremely thick films. After the plate has been bleached, a second washing for five to six minutes will suffice before transferring it to the ammonia bath; but the second washing may be reduced to half a minute if sulphite of soda be used instead of ammonia. To facilitate the removal of the bichloride of mercury from the film, it is desirable to add common salt to the solution of bichloride of mercury. It also expedites the solution of the bichloride of mercury. The following proportions are given:—

Bichloride of mercury .....	20 grammes.
Common salt .....	40 "
Water .....	1000 c.c.

The salt renders the addition of bromide of potassium to the bath unnecessary. It has a similar effect and is less expensive. It is very desirable to keep the bichloride bath in an acid condition by adding hydrochloric acid until blue litmus paper is turned distinctly red. This will keep the solution quite clear. The formation of a white deposit indicates that the bath has become alkaline. The deposit has a tendency to adhere to the film, and is then difficult to remove.

**Discoloured Platinotypes.**—The paragraph by Mr. E. W. Hawes, which appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY on September 22 last, calls forth a comment from the editor of the *Photographische Mittheilungen*. Mr. Hawes attributes the yellowing of platinotype prints to the action of the acid bath, and recommends a neutralising bath of soda. The editor of the *Photographische Mittheilungen* doubts if the change of colour is due to hydrochloric acid. From his experience he attributes it to traces of platinum salts, which may be left behind even after careful treatment with acid baths and subsequent prolonged washing. Discolouration is associated more particularly with paper sized with gelatine, while paper sized with arrow-root rarely shows the defect after careful treatment. Gelatine has a well-known tenacity for various salts.

**A Copyright Question.**—*Le Moniteur de la Photographie* publishes a very interesting decision, which has recently been given in the French law courts. Clara Ward, otherwise known as Princess de Chimay, sat to P. Nadar, of Paris, for her photograph, and paid the usual charge. She also gave him permission to use the photograph commercially. The editor of the *Nouvelle Revue Parisienne* applied to P. Nadar for permission to reproduce the photograph on the cover of his paper, as he was about to publish an article relating to the Princess. P. Nadar refused, and the editor then obtained permission from the Princess de Chimay. The *Revue Parisienne* was seized at the instance of P. Nadar, and legal proceedings were instituted. The case involved further points, as the *Revue Parisienne*, although a Parisian paper published in Paris, was printed in Belgium. The judgment was in favour of P. Nadar upon all points, and right of publication must therefore be obtained from the photographer, according to French law, even if the sitter has paid for the photographs.

**The Colour of Transparencies.**—There is a short account in the *Photographische Correspondenz* of some experiments made by Dr. Eder concerning the colour of the image upon chloro-bromide plates as affected by the nature of the light to which they are exposed. Edwards's plates and hydroquinone developer were used. The light of a paraffin lamp and ordinary daylight favoured blackish tones. Incandescent gaslight, under otherwise similar conditions, tended to brownish tones. This seems to indicate that the chloride is more affected than the bromide by exposure to incandescent gaslight, which is richer in violet rays than the light of a paraffin lamp. The maximum sensitiveness of chloride of silver is nearer the violet end of the spectrum than that of bromide.

**Peroxide of Hydrogen.**—The *Photographisches Wochenblatt* gives an abstract of a paper read by Dr. Andreesen at the Berlin Photographic Society concerning peroxide of hydrogen as a developer and a reducer. Like hydroxylamine it has the properties of a developer, but it must be made strongly alkaline by adding two molecules of caustic potash to each molecule of peroxide of hydrogen. Although the fact is very interesting from a theoretical point of view, as it presents the apparent anomaly of an oxidising substance acting as a developer, whilst it confirms the law of the atomic construction of developing agents, it is, nevertheless, of no practical value, because oxygen is liberated and riddles the film with small bubbles. For use as a reducer hydrochloric acid should be added to the ordinary commercial three per cent. solution. It first attacks the densest parts of the negative, and, as it also dissolves the gelatine, it forms a strong relief.

**Platinum Toning.**—The *Gazette du Photographe Amateur* publishes the following toning process, recommended by M. A. Courrèges, for very rich, warm, black tones. The following solutions should be prepared:—

No. 1.	
Water .....	500 grammes.
Borax .....	10 "
No. 2.	
Water .....	500 grammes.
Chloride of gold .....	1 gramme.
No. 3.	
Water .....	1000 grammes.
Chloro-platinite of potash .....	1 gramme.
Phosphoric acid .....	10 grammes.

A few hours before toning, mix 60 grammes of No. 1 with 60 grammes of No. 2. The solution should be neutral when used. This may be ascertained by the colour, as the yellowish tinge, due to the chloride of gold, should be discharged. Keep the bath after use as stock solution, and make fresh additions to it for each batch of prints. The prints should be well washed before toning in the gold bath, and they should be removed from the latter as soon as the high lights turn grey when examined by transmitted light. Rinse them in two changes of water, and carefully drain them to avoid diluting the platinum bath, No. 3, which should then follow. Fix and wash in the usual manner.

**Erythrosine and Bichromate Films.**—The *Photographische Chronik* mentions that the sensitiveness of the bichromate processes may be considerably enhanced by the use of erythrosine.

As an instance, it mentions that the exposure of an ordinary collo type plate was reduced to an hour and a half in bad winter light whereas in the ordinary way it took two and a half days to print under the same conditions. Similar results have been observed with photo-litho paper and the fish-glue and albumen processes.

**The Paper Ring.**—We also notice in the same paper an extract from the *Papier Zeitung*, which states that O. S. Greenleaf, of Springfield, Mass., has bought the Springdale Paper Mills at Westfield, Mass., and, with the assistance of J. B. Mumford, who has studied the manufacture technically in Germany, will organize them for the production of photographic papers. The experiment is supported by the American trade as a means of combating the monopoly of the Steinbach-Kléber combination. The factory will produce 2500 kilos daily.

#### MR. HENRY STEVENS AT THE CAMERA CLUB.

The little band of photo-fakers which makes so much noise in its efforts to convert pictorial photography into a thing of shreds and patches knocks in vain at the doors of the Camera Club. They are "not taking any" in Charing Cross-road. Landscapes false in tone values, topped by clouds whose relationship to the rest of the picture is distinctly antagonistic, would not be regarded, we imagine, by the seven or eight hundred educated gentlemen who constitute one of the most enlightened photographic assemblies in the world with the same feelings as the raw and credulous provincial amateur. Vamped-up travesties of nature, accompanied by a whirl of meaningless words, may pass as pictorial photography with a not very exalted order of intellect, but a careful scrutiny of the one and an analysis of the other soon reveal meritriciousness allied with verbal vagueness. In other words, "fake" can only deceive the ignorant.

Only a few weeks ago Mr. E. R. Ashton occupied the large room at the Camera Club with an exhibition of Egyptian scenes produced by unfaked photography, and he has been succeeded by Mr. Henry Stevens, who for many years past has been noted for his beautiful studies of flowers, the outcome of a most intelligent handling of lens, dry plate, and printing surface. On the present occasion Mr. Stevens also shows us a number of flower studies, and we have besides human and animal portraiture in extensive variety. Always recognised as having as complete a command over successful dog and cat photography as over the properly gradated delineation of flowers, Mr. Stevens comes forward in the unfamiliar rôle of an exponent of child portraiture, and scores an undoubted success. A charming child, with a most expressive face, forms the subject of a good many of his photographs at the Camera Club, and the variety of poses in which Mr. Stevens has succeeded in representing the graceful little lady, amidst home surroundings, show him to be the possessor of a very wide range of photographic skill indeed.

Then we have a large number of cat, rabbit, and fox-terrier studies of a most lifelike character, skating scenes, costume portraits, fancy heads, and other subjects. Mr. Stevens perhaps shows to most advantage in the studies of the little girl and the portraits of the animals (who look a very happy family indeed); but the work, photographically regarded, is strong throughout, that is to say, the poses have been well chosen, the lighting is generally natural, the exposures adequate, the printing well and carefully done, and having a richness and depth which is a treat to contemplate in these times of a mild epidemic of measly gum bichromates and other rubbish.

Mr. Stevens is quite the Briton Riviere of photography. Pictorially regarded, his work is interesting and unforced; in the technical sense, it supplies a valuable lesson in what is best in photographic manipulation. Such work is not for a day, but for all time. It can be "lived" with.

The photographs will be on view till the end of January, and we hope that the Camera Club will arrange other exhibitions of good photography produced by men who are sincere in their work, and whose interest in pictorial photography is not of that commercial kind which manifests itself in what the French happily term the *réclame*. The best workers in photography allow their work to speak for itself.

#### ON SAVAGES, ADVERTISEMENTS, AND THE ALMANAC.

In spite of our boasted civilisation we are but savages yet. We pride ourselves on being eminently practical, and look on all sentiment as childish; but, for all that, our instincts, call them savage or childish as you please, will assert themselves.

So I said to myself when Jones dropped in the other night, as I saw

him turning over the pages of the ALMANAC. Now, you must know that Jones is pre-eminently practical, he has a reason for everything he does; he is an authority on optics, and what he does not know about chemistry is as yet unknown. His negatives are always done to a turn, they are invariably perfect in gradation and definition. I hope you have gathered from this what kind of a man Jones is. Well, when he got hold of the ALMANAC, he looked it through as any child or savage would have done. Holding the weighty volume in his right hand, he opened the front side of the book, which most people ignorantly call the back, I generally call it the back myself, much to the disgust of my bookbinder, who must be tired of explaining that the back is not the side, but that part which is seen when the book is on the shelf; he reads there a few words, "With the Editor's Compliments," which makes Jones envious of me, then his savage instincts get the master of him. No, he does not put the book under his arm, he could not put it in his pocket if he was to try, he has not one big enough, and rush away with it. If he did so, I should have to turn savage too, and put out my foot to trip him up before he got off my carpet. No, he bends back the fifteen-hundred-and-sixteenth leaf with his left thumb, and quickly turns the rest of the leaves over towards the beginning, stopping only when he gets to page 634—stops as a child or a savage when he sees a pretty picture, then after a good long look he skims away to page 1.

Mind, I was watching him carefully all the time and was anxious to see what he did next. I expected he would turn to the contents index, like a learned man, but no, he started again at the end, going this time rather slower, he stopped a second at page 1427, and again at 1272 and 1271. When I said, looking at the old salt, "Is that beyond the pale?" he gave a grunt. The savage again, you see, and turned on, not to stop again till page 1114; then he flew along to 1018, then to 954. This seemed to fetch him very much; then to 890, next to 826, then to 765 and 764 and 762, then away he went to 730 and stopped again at 634. At this I could not help laughing outright, for he had been looking at the pictures.

After Jones had gone, as I sat thinking how childish and savage such a learned man had shown himself, it seemed as if a ray of hope shone forth for those of us who try to make pictures. At present pictures are a drug on the market for they are of no use; but it really seems as if pictures were at last to be both useful and ornamental. If advertisers, wide-awake men every one of them, find that pictorial advertisements catch the eye and arrest the attention when plain type or blocks fail to do so, why, then there will be a demand for pictures.

There are people, however, who pretend that they never look at advertisements, pictorial or otherwise; but such beings, if there are any, cannot be unaware of the existence of such things.

Some years ago I took in the —, a paper which had very few advertisements. Then I began to reason with myself. This paper cannot be a good one, it cannot be healthy, its circulation must be bad, or more people would advertise in it. So I looked about for another and found one with more advertisements, a paper which I have subscribed to ever since, and which teaches me more than ten times what the other one did. Evidently the advertisers are able to smell out what is good.

Speaking of advertisements, I do not remember having seen in any paper such telling advertisements as have been appearing in THE BRITISH JOURNAL OF PHOTOGRAPHY during the past twelve months. I allude to Wellington & Ward's Signs of the Zodiac, designed by Walton & Co.

Some people say they throw away all loose advertisements. I have collected all these, and have made a frieze of twelve of them round my office, giving the place of honour to Aries.

It may be that pictures supply a want which our boasted civilisation feels the need of. Now that countless thousands are unable to hold that close communion with nature which their ancestors enjoyed, it may be that, no matter how learned a man may be, or how many letters he may have after his name, he will always stop instinctively at the sight of a picture. The better the picture, the longer he will stop. That must be why Jones looked so long at the picture in the ALMANAC—which is placed where pictures have been put in the ALMANACS for the past I don't know how many years—at that place where the advertisements end and the literary matter begins.

The ALMANAC does for us what we should otherwise have to do for ourselves. It condenses the past year's photographic progress as an ox is condensed into a jar of meat extract. When I began photography I borrowed the BRITISH JOURNAL for the previous twenty years, and condensed those twenty volumes into one, indexed one for my own use before I ever took a negative.

ZWITTAU.

## THE CHEMISTRY OF PHOTOGRAPHY IN RELATION TO DEVELOPMENT.

[A Paper read before the Edinburgh Photographic Society.]

To have a correct understanding of what happens—that is, what chemical change occurs—when the developing solution is poured upon the exposed plate, it is necessary, first of all, to inquire in what way the plate has altered by the exposure in the camera; and to this end I would wish to bring before you the behaviour of the halogen salts of silver when brought under the influence of light, giving, at the same time a short account of some experiments I carried out in this direction during the past summer.

There are numbers of substances which undergo either a chemical or physical change when exposed to light. Of the former (chemical change) the reduction of such salts as ferric chloride into ferrous chloride in presence of oxidisable matter may serve as one example, while for the latter (physical change) yellow phosphorus becoming in sunlight red or amorphous phosphorus is sufficiently familiar. Of such there is no time to-night to deal; rather let us confine our attention to the text of this part of the subject, and consider only the salts of silver and the photo-chemical changes brought about by the action of light upon them. It is well, however, to notice—and photographers might be apt to overlook the fact—that other substances besides salts of silver are, as I have said, changed by the sun's rays. It may be stated broadly that all silver salts are changed by the influence of light; some of the salts require the presence of other bodies to effect the change, some do not.

The silver compounds with which the photographer has mainly to deal are the nitrate, chloride, iodide and bromide of silver. The last three salts are called the halogen salts of silver, or silver haloids. It is with these that we are specially concerned to-night.

Now, to have a clear conception of the matter, the properties and appearances of each of the three salts must be examined, and their mode of formation understood. A mixture of the haloids must also be made and critically examined. Then all must be exposed to bright sunlight, and the photo-chemical change noted. It is the last part of the investigation that has puzzled so many observers, for we are brought face to face with that most mysterious thing, the latent image.

I do not presume—and I want to emphasise the statement—to offer a solution of the matter. All I can do is to report to you the chemical investigations I have conducted during the past brilliant summer, with the hope of adding a little to our knowledge on the subject and stimulate investigation, and likewise to bring before you the views of other workers in the same direction and the conclusions they were led to make.

Let us begin with the chloride of silver. It is an elementary fact to the student of chemistry that, when a soluble chloride is added to a solution of nitrate of silver, a white precipitate of chloride of silver is produced—formula  $\text{AgCl}$ . It was known even to the alchemists that on exposure to light this substance became dark in colour.

In the early part of the late summer I prepared a quantity of chloride of silver, and exposed it under water to the brightest sunlight for some days in June. A brownish-violet product is the visible result (which I have in this bottle), but another change at least has occurred. A certain photo-chemical decomposition has taken place—the original white chloride of silver has, during the process of darkening, lost some of its chlorine. This chlorine I found, by several chemical tests, in the water above the precipitate. The question now is, what insoluble compounds of silver remain? An answer to this question would go far to explain the composition and properties of the latent image. Now, precipitated chloride of silver is readily soluble in a solution of ammonia. If, therefore, the darkened chloride is treated with ammonia, nearly all the precipitate disappears, but a dark flocculent residue is left, which is not soluble in this reagent. The quantity left undissolved is so minute that it may not be possible to demonstrate it as an experiment, especially at night. The eminent Swedish chemist, Scheele, stated that this insoluble residue is metallic silver, and, it is said, he proved it to be so by dissolving it in nitric acid, which is a solvent for that metal.

I have endeavoured to repeat Scheele's investigation. The darkened chloride before referred to was treated with ammonia, and any insoluble matter allowed to deposit, and the supernatant fluid carefully decanted and residue washed with pure water until quite free from soluble silver salts. The minute black residue was next treated with nitric acid, in which it readily dissolved, but on the addition of hydrochloric acid no precipitate was produced.

The negative results indicate the absence of silver in the residue. What the latter is I have not yet determined, but purpose making a special investigation with large quantities of chloride of silver. I made another research to ascertain if the coloured chloride contained metallic silver. You are aware that mercury readily forms an amalgam with gold and silver. Now, if mercury be added to the darkened product, and the latter contains elementary silver, one would expect to get this amalgam, which could readily be examined for silver. The addition of mercury was made under various conditions, but I failed to re-establish the white colour of the original silver chloride; indeed, it was not possible to detect any outward and visible change in the latter. The mercury, on the other hand, was also examined for silver, and I obtained clear indications of its presence. The black residue, which, presumably, is the cause of the change in colour of the exposed chloride, does not appear to be metallic silver, but yet it is some body which unites with mercury. Were it silver, then the loss of the halogen and the reduction of the salt to metallic state are represented by a very simple chemical equation,  $2\text{AgCl} = 2\text{Ag} + \text{Cl}_2$ , and the developing process is capable of ready comprehension. The nature of the composition of the darkened chloride has given rise to much controversy. The view held by many is that the change is due to the formation of a new substance which they call subchloride of silver, having the formula  $\text{Ag}_2\text{Cl}$ . They argued in this fashion: If chlorine is given off when chloride of silver is exposed to light and becomes dark in colour, and that this darkening takes place even in presence of nitric acid, as I have proved it does, though not so readily, indicating it is not

metallic silver that is formed, then what can the darkened substance be but subchloride?

There is no doubt on one point, viz., the darkening is not due to an allotropic condition, as may be seen in the case of phosphorus, but a true chemical change has occurred and chlorine has been lost. Why, then, should the violet body not be a subchloride? To prove that the white chloride on exposure actually does lose an appreciable quantity of chlorine, I took 100 grains of pure crystallised silver nitrate and precipitated the silver by hydrochloric acid, and washed the precipitate repeatedly by decantation with pure water, exposing it during all the time in exceptionally bright, sunny weather. It was then dried. The resulting chloride of silver by theory should have weighed 84.41 grains. I obtained only 83.64 grains—difference, .77 grain. There is a limit to the loss of chlorine and the darkening; if this were not so, the difficulties of working with minute quantities of the altered compound would disappear, and the problem would be thus less difficult to solve. I exposed the chloride in flat porcelain trays for days on end to the sun, but a stage was soon reached when the chloride no longer darkened, and when the chlorine dissolved out in extremely minute quantities.

It would take us rather far to give chemical reasons against the view that a subchloride of silver is formed; but it seems to me that chemical theory and analogy are against the supposition, at all events, that the reduction product is represented correctly by the exceedingly simple formula  $\text{Ag}_2\text{Cl}$ , though I do not for a moment say that it may not be. Before going farther with this subject, let us glance for a little at what the father of photography discovered in regard to the sensitiveness of the silver haloids and the development of the latent image—I refer, of course, to Daguerre. Let me recall the principles upon which his process rests. A perfectly clean and burnished silver plate, or copper plate electro-plated with silver, is sensitised by exposing it to the vapour of iodine in a box until the whole surface of the plate receives a thin coat of silver iodide—subsequent investigation showed that a second treatment, this time with the vapour of bromine, greatly increases the sensitiveness. A few seconds' exposure in the camera is all that is required, and the development is effected by exposing the plate face downwards to mercury heated in a box to a temperature of about  $50^\circ \text{C}$ . As in other development processes, the progress must be watched and the correct depth reached. The image is fixed with solution of thiosulphate of soda, as with the plate used to-day. The theory of the development is that the reduced silver haloid—i.e., the reduction product—whatever exact chemical compound it may be, has an affinity for mercury—at least, mercury has some kind of action on it. The image is quite invisible before the addition of the developer, and this is the great point brought out by the discovery of Daguerre—a latent image that is visible only after development. The Daguerre plate may be developed with either an acid solution of sulphate of iron, as a wet plate, or with pyrogallol. It was proved later that the silver plate so coated is more sensitive than a washed collodion plate; there is, therefore, some sensitiser present in the former which is not in the latter, and this was believed, and is proved later, to be metallic silver forming a salt with the liberated halogen. The solution of silver nitrate in the wet plate acts in the same way. Wash the wet plate and you diminish the sensitiveness enormously, for by so doing you remove the absorbent or sensitiser. It is stated that a change in the structure of the exposed Daguerre plate has been observed. The altered product is somewhat powdery, and is capable of being removed by rubbing.

Now let us return to the appearance and properties of the silver haloids, for the one brought before you (chloride of silver) is not always used in photography.

It may seem strange that the image on the plate after exposure is invisible, but on reflection this will not be so mysterious for two reasons: first, because a very minute quantity of reduction product is formed; and second, because, as I shall show you, pure bromide of silver is much less, and pure iodide of silver scarcely at all, darkened by light.

Here is some of the latter (iodide of silver). This sample has been exposed to the sun's rays about the same time as the chloride, and see how little it has changed from the pale yellow colour it originally had. One hundred grains of pure nitrate of silver, when precipitated with potassium bromide and then exposed to bright light, gave 110.08 grains of bromide of silver, while theoretically I should have got 110.58 grains, or .5 grain less than theory, showing bromine is lost. In the same way, iodide of silver was prepared from 100 grains nitrate, and, while theory shows 138.23 grains, I obtained only 137.06 grains.

In presence of an absorbent for the halogen, the decomposition of the salt of silver is more readily effected. To show that, I exposed both the bromide and the iodide of silver to bright light in presence of a solution of silver nitrate, imitating to some extent what happens in the wet plate. You will observe the exposed products are visibly darker than these where no absorbent was present.

Now, collodion is not a halogen absorber, but gelatine is—so that, when, say, bromine is given off during the exposure of the plate, it is greedily taken up by the gelatine in intimate contact with it. This helps to account for the extreme rapidity of the modern gelatine plate.

The degree of darkening of the silver haloids must not, however, be taken as a measure of their sensitiveness in the photographic sense, and it is somewhat curious that of all the haloids the most sensitive in this respect is the iodide, which, as we have seen, is the least visibly affected by light.

Here is still another view as to the constitution of the darkened product, and a certain amount of countenance is given to it by Meldola and others; this is that an oxychloride is formed,  $\text{Ag}_2\text{OCl}_2$ . Against this view we find Mr. Cary Lea, who proved that the reduced body contains no oxygen. Another investigator showed that the former was stable at the fusing point of the silver chloride with which it is associated (see *Journal of the Chemical Society*, pp. 537-1891), and it is assumed that stability is not a characteristic of an oxygen compound of silver.

Let us now look for a time at the theory of development, which, if viewed in the light of the reduction product being metallic silver, admits of ready comprehension.

Meldola defines a developer as a substance which exerts an action upon those portions of a photo-sensitive compound which have been exposed to light different to that which it exerts upon the unexposed portions. What is the invisible image? It is believed to be of the same chemical composition as the darkened products. It consists, therefore, of the unaltered haloids along with a small amount of the reduction products—that some of the halogens have been expelled from the original salts as they existed before exposure, and have been absorbed by some body present which may be called the sensitiser, and the rapidity of the plate greatly depends upon the affinity between the absorbent and the absorbed.

Take the case, again, of the old wet plate. Here the sensitiser is the solution of silver nitrate, which readily reacts and forms definite chemical compounds with the iodine or bromine liberated during exposure:—

Again, take the once familiar tannin dry plate. Here the sensitiser is the tannin; and, lastly, the gelatine acts in this way in the plate of to-day, the sensitising action being due to their affinity for the free halogen.

The developer commonly used with the old wet plate was an acid solution of sulphate of iron. Now, if to a solution of nitrate of silver we add some ferrous sulphate, a dark-coloured precipitate of metallic silver is soon produced, the ferrous salts being at the same time oxidised to the ferric state. According to the equation

the action is too rapid, and a developer so used would speedily fog the plate. To avoid this, acetic acid or some other restraining agent is added, and the deposit of silver is more slowly and gradually thrown down. This is precisely what is required in a developer. The deposited metal adheres to or combines with the decomposition product, and a picture is thus formed by accretion of the molecules. The action is cumulative, and the negative gains in density as long as it is supplied with fresh silver. This is an example of acid development; the use of an alkaline developer for this is quite inadmissible. The development of the wet plate is a surface development, for the silver salt is on the top of the film.

What is essentially required in a developer for the wet plate is a reducing action on the nitrate of silver and no action on the unaltered silver salt, along with this a restrainer must be present.

Another developer very familiar to us all is pyrogallol. Now, the great property of this substance is its intense affinity for oxygen, and its powerful reducing effect on salts of silver and gold. If we add a solution of nitrate of silver to pyrogallol, a precipitate of metallic silver is very speedily produced, but the action is so rapid that fog would result, and, to retard this, bromide of potassium is added as a restrainer, the retarding effect being due to the formation of a more stable double salt with the silver, which is less rapidly reducible than the bromide of silver alone. In this way the reduction to the metallic state of the unaltered iodides and bromides is much more slow. You will here observe a very marked difference in the action of the two developers. The sulphate of iron has no tendency to reduce the unaltered silver haloids, but only the silver nitrate in solution on the wet plate, and this deposited silver, as we have seen, accumulates upon the reduction products. The alkaline pyrogallol solution, on the other hand, reduces the insoluble silver haloids as well as the soluble silver nitrate to the metallic state, and on this account it requires restraining by bromide of potassium. At the same time it must be noted that the reduction of the altered halogens takes place before the unaltered group, and this is the reason of the action of the alkaline pyro on the latent image taking place before the former.

Another well-known developer is ferrous oxalate. It acts much in the same way as alkaline pyrogallol—that is, as a strong reducing agent. The oxalate is really a double salt with the formula  $\text{K}_2\text{Fe}(\text{C}_2\text{O}_4)_2$ , and is prepared by the double decomposition of one molecule of ferrous sulphate and two molecules oxalate of potash.

The chemical action of this developer is as follows: The ferrous salt is oxidised to the ferric state  $\text{Fe}_2\text{O}_3$  by the bromine from the reduction product, and the latter is in turn reduced to metallic silver. In the acid development the image is built up on the surface of the negative, but in the alkaline development the reverse is the case. The picture is sunk into the gelatine, and this is caused by the newly reduced silver from the reduction product being capable of taking more silver from the unchanged silver salts in the emulsion in immediate contact, and in which it is imbedded.

This fact accounts for the sinking of the image in the gelatine film, the supply of silver coming, in the first place, from the reduction product,

but after that it is added to by growth from below. If, therefore, the gelatine negative be treated with nitric acid to remove metallic silver, the impression is left sunk into the emulsion. With acid development this is not so, the image simply disappears in nitric acid. How the unreduced haloids are acted upon by the silver during development is not fully made out, but the action is believed to be an electrolytic one, and it appears there are some good grounds for this belief.

It must not be overlooked that not only the sensitive silver salts take part in the development, but also, and very largely, is the sensitiser a factor in the case.

In the gelatine plate the intimate mixture of the gelatine with the silver salts, resulting as it does in a semi-inert condition of the latter, permits the use of strong developer for these plates, and in this way we are able to work with minimum exposures. Without the presence of the protecting gelatine, which acts as a kind of envelope and retards the action, these strong developers would speedily reduce the haloids direct to metallic silver with disastrous results. As an amateur photographer who began his work with wet plate, tent, and stand, and all the inconveniences attending them, a scorching sun and fitful winds added to the misery; the latter had a habit of upsetting not only the tent and all its contents, including the whole-plate bath, but even the amateur tied inside. In those days it did require some enthusiasm to prosecute the art. Now all is changed. No developer need find its way into the sensitising bath, no tent is required, and the development may be conducted ten thousand miles from the subject, and many months after the event. What a boon this is to all photographers, and not a little is due to the extreme suitability of the present-day alkaline developers. J. B. READMAN, D.Sc.

#### THE ELEMENTARY PRINCIPLES AND PRACTICAL USES OF THE PHOTOGRAPHIC LENS.

A LECTURE on this subject was delivered to the Thornton Heath Polytechnic Photographic Society by Mr. F. O. Bynoe, on Tuesday, December 12.

In his opening remarks he pointed out the importance to every photographer, whether professional or amateur, of some acquaintance with the construction and working of the most valuable element in his apparatus, whereby he could ascertain what to expect and what not to expect from its working. It was almost impossible to obtain these necessary details from books, and he must warn his hearers that, though much thought had been expended upon the perfecting of lenses, they were still more or less imperfect, and must be dealt with accordingly.

The first division of his syllabus being "The action of the lens in producing the photographic image," Mr. Bynoe referred to the possibility of producing an image by means of a mere pinhole, and, by the aid of a diagram, demonstrated the collection and subsequent distribution of the rays of light by this method. The advancement in speed of action was, however, shown to be due to the introduction of a lens, whereby a much larger volume of light could be concentrated on the plate, and its action thereon consequently accelerated. Though not necessary for practical purposes, it had been proved that, in so minute a space of time as the  $\frac{1}{1000}$  of a second, a photographic image had been secured.

Proceeding to his second division, "Something about light," the lecturer stated that no theory entirely explained all its phenomena, but the theory that it travelled in transverse waves was universally admitted, and this motion was illustrated by a most ingenious mechanical slide constructed by Mr. Bynoe. Darting through the luminiferous ether, which pervaded our atmosphere and possibly the whole of space, as well as most of the apparently solid bodies, the waves of light travel in all directions, and (unless deflected by intervening media) in straight lines, and, as shown by the wonderful rays from the fixed stars, they were eternal when once they had commenced their course. When they came into contact with any material object, the rays were either reflected, as from the surface of a mirror; dispersed, as from an object not having a polished surface; or absorbed, as by an object having little or no power of reflection. These phenomena were not only lucidly illustrated by carefully drawn diagrams, but by the deflection of the lantern rays by a mirror, and by their practical disappearance when projected upon a dull black card. This was followed by other diagrams showing the bending of the rays when they were passed through various transparent media, and the peculiar action of the prism, not only in diverting the rays into a new direction, but in dispersing and decomposing them into the colours of the spectrum, was shown by means of a second lantern and screen. The white rays were first seen in a direct line with the lens; a prism was then interposed, and the spectrum appeared in all its beautiful gradations, which, being again collected by another lens, reappeared in their original form. This demonstration was highly appreciated by the audience, and elicited loud applause.

By the process of refraction it was seen that the red rays changed their line of direction the least, and the violet the most, the red rays having the slowest vibratory motion and the violet the most rapid. For photographic purposes the red and yellow rays were of little value, the green and violet being the most important, but a proportion of yellow

light was also necessary for illumination. A properly corrected lens was therefore necessary to secure what was known by opticians as the effective chemical focus. Proceeding to the consideration of "the lens and how it does its work," by the aid of further diagrams Mr. Bynoe showed that every lens might be taken as consisting of a series of prisms, and exhibited sections of the double convex, the convex plane, the meniscus, the concave plane, and the double concave lenses, illustrating, by means of lines, the faculty of each form in converging or diverging the rays of light that passed through them. But the mere form of a lens did not suffice to accomplish colour correction, therefore it was necessary to combine different qualities of glass, flint glass having a higher dispersive power than crown, and by the combination of the two in certain forms an achromatic lens was constructed, and a practically perfect focus obtained. The theory of focussing was next considered, and illustrations were given of the crossing of the rays of light as they passed through different sections of a lens, creating what is known as the caustic curve. This produced a spreading of the focus, and, if not reduced to a minimum, would cause a blurred image. This led to the consideration of what is known as spherical aberration, and, by drawings upon a black-board, Mr. Bynoe essayed the difficult task of explaining this point, showing that, every lens being a portion of a sphere, the optician had not only to contend with direct but oblique rays of light, and therefore must adjust his lens in such a manner that all the focal lines were properly directed into a true focus. He then demonstrated astigmatism, by withdrawing from the lantern one of the combinations, and projecting the light through what might be described as a badly corrected lens, whereby a diagram consisting of a number of radiating lines, bearing other cross lines, was shown upon the screen. The alteration of focus caused the radiating lines to be seen to be sharp, while the cross lines were blurred, and, when the latter were corrected, the former became indistinct. The change back to the properly corrected lens secured a practically perfect focus for the test diagram, though a very slight blurring was still evident at its extremities, which suggested to Mr. Bynoe to remind his audience that absolute perfection in a photographic lens had yet to be attained, and that, as it was so difficult to correct for all errors, the present lenses must be accepted as the best compromises that opticians could give them.

The causes of distortion of the image were then discussed, and the effects of barrel and pin-cushion distortion shown by diagrams, with their neutralisation by the combination of lenses known as the rapid rectilinear. The construction of wide and narrow-angle lenses was also demonstrated, and the lecturer proceeded to explain what was meant by the curvature of field, stating that all lenses were more or less subject to that fault, and that in this particular a compromise between extremes was all that could be at present effected. The value of stops was then commented upon in their effect in assisting the lens to efficiently cover the plate, thus securing clear definition at the edges. The consideration of depth of focus naturally followed, and it was shown that the correction of lenses with that object in view had again to be accomplished only by compromise. Stopping down increased the depth of focus, so that the sharpness of all objects at varying distances could be thereby attained; but, as that advantage was counterbalanced by diminution of light, the time of exposure must be extended. In photographing interiors or other motionless objects time was not generally of importance; it was therefore desirable in such cases to stop down to the utmost possible limit.

Mr. Bynoe said that, as no one lens was universally applicable to all subjects for the best results, a proper selection of the lens to be used in certain cases was desirable. The impression on the plate depended almost entirely on the relation between the diameter of the lens and the length of its focus, and, as that was varied and regulated by the stops that were used, it explained the meaning of the figures with which they were familiar— $f/4$ ,  $f/11$ , &c. For their guidance in the selection of lenses he would certainly advise a portrait lens for perfect portraiture, and a rapid rectilinear for architectural or other work where the preservation of upright lines was necessary, but for general landscape photography he considered that a single lens of good quality was quite sufficiently satisfactory. Every optician was aiming at the production of lenses with as flat a field as possible, and for copying objects with a plane surface the flat field was essential, but it was not always so useful for ordinary work. He would therefore conclude by advising amateur photographers not to be discouraged by the lens they possessed, but to persevere in endeavouring to gain perfection by patient experience, and he trusted that his remarks on that occasion would assist them to make progress in the desired direction.

#### NOTES ON OZOTYPE.

At a meeting of the Leeds Camera Club, on Wednesday, December 13, a lecture was given by Mr. Thos. Manly, on "Ozotype," of which he is the discoverer. Ozotype is an important development in carbon printing, the essential difference being that in this process there is a visible image, while in the ordinary form of carbon working there is none. The image is printed on the transfer paper, and the tissue is then brought into contact with it. The print is formed by the chemical action of certain salts with which the transfer paper is coated. This solution is protected by letters patent, and will be shortly on the market. Any pure

paper may be used, and is evenly coated with the sensitising solution, and dried in the dark. It will keep well for a month or six weeks if kept dry. It is placed under the negative in the ordinary way, and the image is clearly and distinctly visible of a brown colour, and printing is stopped when faint detail in the high lights is visible. The image is much more distinct than it is in platinotype. The print is then well washed, and in this state can be put aside for an unlimited time, and subsequent operations conducted at leisure. A piece of ordinary carbon tissue, insensitive, is now placed in an acetic solution of—

Water .....	40 ounces,
Glacial acetic acid .....	80 minims,
Hydroquinone .....	30 grains,
Glycerine .....	1 drachm,

and allowed to remain about a minute. The print is now plunged under the surface of the solution, brought into contact with the carbon tissue, and quickly withdrawn. Squeegee the two surfaces together, and allow to dry. It is then developed as a carbon print, giving a correct image, while the ordinary single carbon transfer gives a reversed image. The subsequent print is in every respect equal to any carbon print, with the advantage of possessing greater softness of outline and perfect half-tones. The prints may be coloured instead of being pigmented with the carbon tissue by using a colourless salt of aniline, strongly acidulated with sulphuric acid, pleasing and brilliant colours obtained, and, with subsequent treatment by ammonia and other oxidising agents, different colours produced at will.

### ARCHITECTURAL PHOTOGRAPHY.

BEFORE the members of the Kingston-on-Thames and District Photographic Society, on the 11th inst., Mr. C. H. Oakden, President of the South London Society, delivered an interesting lecture upon "Architectural Photography."

Referring to apparatus, he considered a square camera with good rising front and swing back the best to use, and, if possible, the camera should be altered so as to permit of the dark slide being inserted from either side, which he found a great convenience when working in a confined space by the side of a wall. Speaking of lenses, he objected to the use of wide-angle objectives, excepting in very special cases, upon the ground of exaggerated perspective. April and August he thought the most suitable period of the year for cathedral work. With a good light, using stop *f*/32 and a Castle plate, an exposure of a quarter of an hour would be about correct for an average aisle. For all interior work he recommended slow plates, rich in silver, which should invariably be backed, as a safeguard against halation. As a further antidote against this bugbear of the architectural worker, he recommended a full exposure and quick development. He had, he said, tried all the modern developers, and was of opinion that none of them could beat pyro and ammonia, which he preferred to make up in ten per cent. solutions. For printing, nothing, he considered, was more suitable for architectural subjects than warm carbon or sepia platinotype, though a pleasing warm black might be obtained on the hot bath black paper by exposing to the steam from the oxalate bath for a few seconds before development.

At the conclusion of the lecture Mr. Oakden showed about a hundred slides, which fully sustained his reputation as an architectural worker of the front rank.

### IS COLOUR PHOTOGRAPHY POSSIBLE?

A LECTURE ON "Photographic and Mechanical Modes of Reproduction" was given by Mr. E. H. Micklewood at Plymouth Institution on Thursday, December 14.

The lecturer greatly interested photographers present by his lucid explanation of styles of mechanical art printing, in which photography played a part. In speaking of the collotype printing he incidentally remarked that the humid atmosphere of Plymouth was especially adapted for the process. Referring to the question of the possibility of colour photography, the lecturer expressed the opinion that it was no nearer than when photography was first discovered. The art would never be reached, because colour was not an objective which could be photographed, but was subjective, depending on the action of the human brain. Colour was a matter of so many vibrations per second, and how was it possible for a sensitive surface to have the capacity of permanently recording the varying vibrations? It seemed to him inconceivable that such could be achieved. There were, however, some wonderfully clever ways of introducing colour in which Nature herself did a great part of the work, but the colour had to be supplied even in that method. Ives had succeeded in making colours appear, but he had to take three positives of the original object, after which an instrument was used by which the light filtered through red, yellow, and green glasses. Ives had admitted that colour photography, properly so called, was as far off as ever.

The lecture was admirably illustrated by specimens of art printing.

In the discussion the President (Mr. H. M. Evans) remarked on the rarity of lectures on art in connexion with the Institution, although art

was one of its objects, and that all felt specially gratified at the clever lecture that night.

Mr. R. Smith disagreed with the lecturer's physiological reason concerning colour photography. It was true, colours were subjective in the mind, and were produced by relative rates of vibration, but he thought the same vibration would produce the same colour to any person except where there was colour blindness.

Mr. C. Lane said, from his point of view, the lecture was one of the most interesting he had listened to. Regarding colour photography, he was inclined to think that at the present moment there was no hope of being able to photograph Nature in its true colours.

### LIGHTING: ITS IMPORTANCE IN PHOTOGRAPHY.

#### II.

IN a previous article reference was made to a few branches of photography, and the important part which lighting played in connexion with same.

In commercial work, especially in these days, when so many different articles have to be photographed for the purpose of process blocks being made to illustrate trade catalogues and other similar productions, there are numerous varieties of what may be classed small objects for which special methods of lighting are required, and in not a few instances some of these can be treated quite as successfully by the aid of artificial light as would be the case with daylight, and, since the almost universal introduction of the electric light in our large towns and cities, it is largely employed by process workers, for the special reason, no doubt, that it is available at any moment. There are, however, on the other hand, articles innumerable in which daylight is distinctly preferable to any form of artificial lighting; and, still further, it will be found that some articles, strange to say, are best treated by a combination of both.

A by no means uncommon class of articles that have to be photographed is that of silver coins and medals, in which the great aim is to bring out the inscriptions and design in the strongest possible relief. Some writers in the past have advocated this being performed by the round-about method of taking plaster casts from the original, such casts being effected either with the aid of plaster of Paris, or sulphur, or even the homely stick of good sealing-wax. To my mind, this method entails a needless amount of trouble, and seldom yields a sufficiently sharp image, certainly by no means so clear cut as when the original itself is employed, providing it has been properly placed *in situ*, and lighted so as to bring into bold relief the form and inscription such contains.

Small coins and medals are apt to give trouble from reflections quite as much as larger objects, so that special provision has to be made to avoid these nasty visitors, and hence it has been suggested that the surface of those articles should be treated with some compound, such as putty, &c., when the light surface will become deadened and the reflections avoided. Silversmiths, however, as a rule, strongly object to this application to the extremely fine surfaces they produce on their articles, and the writer knows of one instance in which a very valuable silver ornament was greatly damaged in the hands of a careless photographer connected with process work, who evidently little knew the risk he ran when applying such a compound to a highly burnished silver article.

In point of fact, there is really no need to resort to such measures to overcome reflections in many cases. Isolated instances may be found where it is almost impossible to get rid of such visitors without an application of some kind to the surface, but these are few and far between, and an experienced silversmith can generally give valuable suggestions to any photographer in this direction, and, if necessary, prepare the articles for him.

In dealing with such articles as medals and silver coins, the burnished surfaces of them can frequently be dulled by immersion in a small quantity of ordinary toning bath, i.e., acetate of soda and gold, provided the coins are well brushed out with clean soap and water. It is, however, much to be preferred that all tampering with those articles be avoided, and, whenever possible, reflections be overcome by means of a well-devised system of lighting, and copying the same with long-focus lenses.

Some small articles may be successfully photographed through a long box or tunnel, the sides of which are lined with black velvet, thereby allowing only a vertical light or top light falling on them. A long box having about six inches of its one side cut out answers for this purpose admirably, provided the box be placed in an outside situation and no direct light be allowed to enter the open end, where, of course, the camera is made to face the object. The box thus practically becomes a miniature studio.

Other articles, such as those having a highly enamelled surface, can be well treated without any preparation, by lighting them with reflected light entirely. This form of lighting is best done by artificial light, the article being placed *in situ* in front of the lens. Two powerful paraffin lamps are placed at equal distances on each side of the object, but in the rear of it, and sufficiently to each side as to be outside the field of the lens. In front of the object being photographed are placed two slabs of plaster of Paris, or, at a pinch, two large sheets of blotting-paper tacked to suitable supports. The light from the lamps

strikes the white surface of these reflectors, and is thereby, by means of irregular reflection, caused to light the surface of the enamelled object, and, if the disposition of the lamps and reflectors is carefully adjusted, there will be no trouble from surface reflections, and articles thus lighted are easily photographed by means of ordinary paraffin lamps.

Articles such as china plates and valuable crockery ware likewise require special treatment in lighting. Sometimes work of this description can be got over more satisfactorily when very high-class results are required by applying to the makers of the articles, who will always be only too glad to provide the same pattern in an unglazed form, but, of course, this in many instances is not possible, for old china and similar articles cannot be duplicated in such crude forms. I once photographed for book-illustration purposes a number of these articles, and found that, by a special method of lighting them with daylight in an ordinary room furnished with one window, I was master of the situation. These china plates were placed *in situ* against a velvet background, stretched upon a stout box that sat easily on a table, the box carrying the object was placed right up against the window; in this position the plate appears very dimly lighted, but, the moment reflected light is thrown upon it by means of two white reflectors placed at each side, the plate instantly becomes beautifully lighted and free from reflection.

Those readers of THE BRITISH JOURNAL OF PHOTOGRAPHY who are anxious to execute work of this description should try the following simple experiment, from which much may be learned regarding what can be effected by means of reflected light alone: Let an ordinary dinner plate be placed against an opaque object such as a stout board or box, placing it, say, five feet from the window on a table, so that the plate, when standing on its edge vertically against the box, faces to the inside of the room, or, in other words, when being photographed the lens points straight against the light. After the plate is placed in this position, two pieces of white cardboard are made to throw light by reflection on the plate, one from each side at similar angles. The moment the reflectors are brought into position, that moment the most minute detail in the design of the plate will spring into view, and it is easily photographed without any troublesome reflections, *provided the foreground is prepared with a non-reflecting surface* such as any ordinary dark woollen material, and care be taken to have no bright brass fittings on the camera front. This may be accomplished by cutting a small hole in the focussing cloth, just sufficient to allow of the lens working through it, or, stated simply, when there is nothing to cause reflections, none can be present.

In all copying operations lenses of the longest possible focus should be used. The reason for this was described by the writer in THE BRITISH JOURNAL OF PHOTOGRAPHY some time back.

Other articles require special methods of lighting by reason of their particular shape. In this class may be mentioned delicate skeletons of animals, birds, and fishes, and in this kind of work the difficulty generally takes the form of avoiding objectionable shadows from one part of the object falling upon another portion of it.

In cases of this description much will be found to depend upon the form of the particular objects being dealt with, and, if artificial light be used, it should be diffused through muslin screens, or even ground glass. In almost every instance, however, some provision will require to be made so that the background is able to be placed at some distance behind the object. With dark-coloured objects, white backgrounds, when placed close up, are certain to yield eyesores in the form of shadows, which, of course, must be avoided. These can sometimes be overcome by placing the object being photographed against a sheet of glass having holes drilled through it. By this means almost any object can be held *in situ* against a transparent screen, which will not appear in the negative; and also some articles can be attached to such transparent supports by means of marine glue, and, when a suitable background is placed at a sufficient distance behind these sheets of glass, no eyesores in the shape of shadows will be apparent.

Another class of objects which sometimes give trouble are transparent objects like glass globes containing botanical specimens and suchlike. As a rule, these are best treated by photographing them direct against the light, when, by placing a muslin screen or sheet of ground glass between the window and the object, good results will be obtained.

In all inside work, no matter what the object be that is being photographed, there is always a *best method of lighting* to employ, and it should be the aim of every photographer to reason out in his own mind what that method really is.

Another very difficult class of subject is found in large metal discs or plates bearing designs or inscriptions. Among these may be instanced memorial brasses. These are, by reason of their weight, difficult to handle, and but seldom met with in really suitable positions as regards surroundings and light. Whenever possible, they are best treated exactly as oil paintings, *i.e.*, by lighting them with a very high top light and standing the object vertically.

When this is not available, they may be done by reflected daylight, after the manner described for articles having an enamelled surface like china plates, only greater attention must be paid to the reflectors, seeing the surface is always of considerable extent, and the main point is to equally illuminate the same. A case of this sort recently came under the writer's notice, where, by reason of faulty lighting, much trouble was

experienced in bringing out, even with the utmost care in printing, the fine engraved lines forming the beautiful design of the brass.

If so much thought is required in the lighting of objects indoors, outside subjects offer quite as much scope for the exercise of thought, if any particular effect be desired in the resulting picture.

In the early days of photography—*i.e.*, in dry and wet-collodion days—in landscape working, sunlight was deemed a *sine-quâ-non*, but now, with our rapid plates, all this is changed, and it is impossible for any hard-and-fast lines to be laid down as to the best light to employ in landscape work. So much will depend upon the taste of the worker and his striving to delineate some particular effect in light, and shade, and atmosphere, all of which come under the cloak of what is now termed pictorial photography.

T. N. ARMSTRONG.

### A PORTABLE STUDIO.

HERR SCHAEZTKE has devised a portable studio which shall be capable of being made available, in a very short time, for the taking of views or portraits, whether in confined spaces or in the open, and which shall also be capable of being as easily taken to pieces for transport. Further, to render the taking of views or portraits entirely independent of the state of the weather or the light, by the employment of a special arrangement of parts, so that the operations may take place either by daylight or by artificial light (electric, acetylene, magnesium, and so on), or even with a combination of daylight and artificial light.

Frames composed of iron or wooden (or, say, bamboo) rods, easily detached one from another (and which, in some cases, may be strengthened at the corners by cross pieces), are secured, on two sides thereof, to a skeleton framing, which is made to rest securely upon the floor or ground surface by means of suitable feet. In the three vacant sides of the so-formed three-sided chamber, cross wires are fixed, and upon the latter (always in accordance with the actual amount, or desired amount, of light) are hung a certain number (more or less) of light frames, covered with wire gauze or other suitable medium, said frames being capable of being moved sideways as required. If the operation is not to be effected

by daylight, there will also be provided, preferably below the frame forming the roof, a reflector or mirror suspended at an angle, and capable of angular adjustment, so that a portion of the light desirable from a source outside the chamber shall be thrown in a suitable manner upon the object, and another portion be available for the required front lighting.

The photographic chamber will, for the principal part, be formed of three main frames only, the separate parts of which consist of rods, *a* (say, for example, bamboo canes or the like), which are secured in a suitable manner, either horizontally or vertically, and across the frames formed by the rods, *a*, are attached wires, *b*. The connexion of the parts, *a*, of the framework may, for example, be effected conveniently by means of tubular T or angle pieces, *c*, or in any other suitable manner; it must, however, be so effected that the said parts, *a*, of the framework shall be capable of being quickly, and without much trouble, taken apart, in order that the whole apparatus may be stored with ease in a comparatively small space. The framing which forms the roof of the chamber is, in like manner, formed of rods, *a*, and here also two parallel rods are connected together by means of wires, *b*. These wires, *b*, serve not only as regards the vertical side walls of the chamber, but also as regards the roof,

for the securing or holding of frames, *d*, which are covered with a material through which light can pass, such as wire gauze or the like, as seen at fig. 2. The sides of the frames, *d*, which abut against each other, are rabbeted, so that, when they come together, they make a perfectly close joint. The formation of the rebate may be of different kinds, but, by way of example, the most simple kind for horizontal and vertical abutting edges is shown at figs. 3 and 4, in order to make it possible to employ a side light for the illumination of objects to be photographed. It is advantageous, as may be seen from fig. 1, to provide, at the front portion of the chamber, a reflector or mirror, *g*, which will be capable of turning on a hinge, *h*, so that the same may be altered in position in accordance with the amount of light which it is desired to admit. In order that the chamber so fitted together may stand securely and rigidly, it is advisable to provide the lower ends of the rods, *a*, with feet, *i*, which rods, *a*, near the angular connecting pieces, are also provided with wire struts, *k*, or the like.

If, for the illumination of the object to be photographed (as shown at fig. 1), it is desired that the light shall arrive from the left-hand side, whilst the right side is to be thrown into shadow, the frames, *d*, shown at fig. 2, will be suspended on this right side. These frames carry, for this purpose, at their upper and lateral edges, hangers or hooks, *l*, which take over the wires, *b*, in order that they may be held securely in place. By means of similar hooks, *l*, the frames, *d*, shown in fig. 1, on the right-hand side, will also be suspended upon the wires, *b*, and will also be

correspondingly fastened on the roof of the chamber. It is possible, therefore, by employing a greater or less number of frames, *d*, which are also laterally adjustable, to protect, for example, the right side of the chamber against the entry of light, and thereby to maintain the shadow portions more or less dark, whilst on the left-hand side (according as more or fewer frames), in the same manner, are hung up or otherwise, a smaller or greater amount of light for the illumination of the object may be allowed to enter, and thus it is possible to obtain the desired artistic effect in a far better manner than with glass-houses or rigid structures. By altering the position of the reflector, *g*, the aforesaid illumination can be materially increased in the way well known. Instead of the frames covered with wire gauze, similar frames provided with reflecting surfaces may be suspended, either inside or outside of the chamber, at suitable spots.

At its rear end the chamber is kept open, so that the natural landscape may serve as a background when photographing a person or other object. The operator will also be able, when erecting the chamber, to adapt the position thereof to the situation of the sun at the time. If, instead of natural light, artificial illumination is to be employed, it is possible to close in all sides of the chamber, or only a portion thereof, with the frames, *d* (placed together, and one over the other, or in several layers), in order to obtain the requisite lighting effects; or light from an artificial source may be brought into requisition, in addition to the natural light, in accordance with the effect desired to be produced and the particular object that is photographed.

#### TOMBSTONE PORTRAITURE.

MR. E. CHATHAM has devised a frame for photographs on tombstones. Here is his description of his invention:—

"I construct a frame of any suitable metal or material which will resist the action of the weather, and attach it in any suitable manner to the tombstone or the like. I place in this frame a photograph or portrait of the deceased person, or a number of such photographs or portraits where more than one person is buried in the same grave.

"The frame may form part of the tombstone, cross, wreath, or shade, or may be a separate part fitted thereto, or carried by a standard or standards, or other independent support.

"The body, *a*, of the frame shown in figs. 1 and 2 is made of porcelain, or earthenware, or of any suitable metal or material. Near the top is a scroll, *b*, on which any suitable epitaph, text, motto, or heading, can be moulded, printed, or otherwise produced.

FIG. 1.

FIG. 2.

"In the middle of the body an opening, *c*, is formed to display the photograph or portrait of the deceased person, with or without an inscription, such photograph or portrait being held in a white metal or other frame, *d*, covered by a sheet of glass, *e*, and fastened to the body, *a*,

FIG. 3.

by studs, *f*, or other suitable fastenings or equivalent devices; or instead of having an opening in the porcelain body, and attaching a metal frame to the back, the opening may be dispensed with, and the metal frame attached directly to the front.

FIG. 4.

"The frame may either be let into a recess formed to receive it in a tombstone or the like, or simply attached on the surface with screws or other fastenings, or it may be used alone as a headstone, or may be carried by an independent support like the wire-holder, *g*, shown in figs. 3 and 4."

## A DAYLIGHT DEVELOPING APPARATUS.

This is the invention of Herr R. Fleischer. It comprises a casing having three superposed chambers, A B C, whereof the lower chamber, C, contains the developing, fixing, and washing baths, which in the drawings are shown as contained in a vessel, X, divided by two partitions into three compartments, either of which may be brought into position to receive the film. The intermediate chamber, B, is provided with removable coloured windows, g and r, at opposite sides, through which the film may be viewed by transmitted light. A dipping frame, D, is arranged either between rollers, so as to be capable of being moved up and down from the outside by means of draw cords, or, as shown in the drawings, by slide rods, F. The attachment of the frame to the slide

rods, F F, may be effected by a bayonet or other joint, so that, by simply turning the rods, F F, the frame may be disengaged and allowed to drop into the washing bath of vessel, X, and another frame may be attached to the rods for the reception of the next film to be developed. In the upper edge of the dipping frame is an aperture which comes just opposite a slot in the top of the chamber, A, above which is placed the upper chamber, A, for the introduction of the plate or film, as the case may be, into the dipping frame, D. For this purpose it may be a simple bottomless light-excluding casing, into which casing the plate may be inserted by means of an ordinary changing bag and then caused to slide by its

own gravity into the frame, D, when the apparatus is brought to a properly inclined position. In the case of films, as shown in the drawings, the casing, A, is provided with bearings, i', for the spindle, i, of the film spool, L. The end of the black ribbon K, is conducted through slot, k, of the casing to the outside, whilst the film is led through a metallic guide, P, and between the pair of india-rubber feed rollers, N N, of which one has knobs, n, on the ends of its spindle, in order to enable it to be turned so as to cause the film to descend into the dipping frame, D. Directly underneath the top of the chamber, B, and fitted to work over its slot, is a knife, s, which can be operated from outside by means of a handle, s, for cutting off the film as required.

## ACETONE IN THE DEVELOPER.

[Extract from a paper read at the Celeron Convention of the P. A. of A.]

I WRITE these few lines as a prelude or an excuse for the advocacy of a new developing agency introduced about a year ago, namely, Acetone.

It has, in my hands, shown a superiority over that of the carbonate of soda or of potash, it being used in their stead. It is peculiar in its action. A solution of pyro and sulphite will not answer for a developer, a solution of pyro and acetone will not develop, but together, by the reaction of the acetone on the sulphite solution, sets the developer at work. It does not soften the film or cause it to frill, does not stain or fog under any ordinary conditions. I have used it for a year past in my stereoscopic and landscape work, also in lantern-slide work, with great satisfaction, and feel warranted in recommending it highly. In the formulae I give I claim no originality. I give them as I used them. They can be modified by an increase of water, if the brand of plates or subject works to hardness; or, on the other hand, the addition of a small quantity of a ten per cent. solution of bromide of potassium can be used if deemed necessary, in formulae 1 and 3.

The sulphite of sodium I use is a saturated solution. I take, for instance, a pound bottle of sulphite and fill with water, and, on shaking a few times, it soon becomes saturated, then keep the bottle always at least half full of crystals and full of water. I fancy it keeps its purity better in this shape, and certainly it is much more convenient to make up a small quantity of developer.

Four fluid ounces of saturated solution is equal to one of crystals. Never use water hotter than 90° F. in dissolving the sulphite.

## No. 1.—PYRO.

Water .....	2 fluid ounces.
Saturated solution of sulphite.....	2 fluid drachms.
Acetone .....	1 fluid drachm.
Dry pyro .....	5 grains.

## No. 2.—METOL-HYDROQUINONE.

Water .....	8 fluid ounces.
Metol .....	15 grains.

## Dissolve and add—

Saturated solution sulphite .....	4 fluid ounces.
Hydroquinone .....	60 grains.
Ten per cent. bromide of potassium .....	1 fluid ounce.

## B.

Take of A .....	2 fluid ounces.
Acetone .....	1 fluid ounce.

## No. 3.—EIKO-HYDRO.

Water .....	8 fluid ounces.
Saturated solution sulphite.....	4 " "
Eikonogen .....	50 grains.
Hydroquinone .....	25 " "

## B.

Of above .....	2 fluid ounces.
Acetone .....	1 fluid drachm.

No. 1 is especially good for transparencies and stereoscopic work; No. 2, for Yelox or strong negatives; No. 3, for stereoscopic, landscape, and portrait work.

J. BARDWELL.

## Our Editorial Table.

## A STORAGE TUBE FOR PLATINUM PAPER.

Marion & Co., Soho-square, W.

A VERY slight turn enables the lid of this tube to be removed, and, like the receptacle at the bottom which contains the calcic chloride, it is

deeply sunk on the main tube, so that every precaution is taken to keep the platinum paper in a dry condition. The tube is neatly but strongly made and japanned black, and deserves the attention of those who make platinum prints and require to store the paper.

## THE AMERICAN ANNUAL OF PHOTOGRAPHY.

Edited by W. E. WOODBURY. Price 3s. London: Dawbarn & Ward, 6 Farringdon-avenue.

THE scores of pretty pictures that are given in this well-produced annua would alone suffice to make it an excellent gift book for a photographer, but, when to this feature a great number of theoretical and practical articles on current subjects is added, as well as a mass of formulae and tabular matter of every-day use, it will be seen that, besides being a thing of beauty, it is a helpful companion to the photographer. The American annual well sustains its reputation for taste and effectiveness of "get-up."

## A SIMPLE FORM OF STEREOSCOPE.

W. Tylar, High-street, Aston, Birmingham.

MR. TYLAR sends us his list of shilling packets of stereoscopic slides, which he tells us are having an enormous sale. In order to further their popularity, he has prepared a great number of packets, each containing a sample slide, five half-tone stereographs, and a stereoscope. A packet is sent on application for the very small sum of sevenpence. Judging by the sample submitted to us, the stereoscopic slides are most excellent value for the money. But the stereoscope is also wonderfully cheap and effective. It consists of a rectangular card,  $7 \times 3\frac{1}{2}$  inches, holding, at a separation of about  $2\frac{1}{2}$  inches, a pair of single lenses of about an inch in diameter. For viewing the slides sent this simple form of stereoscope answers admirably. We can recommend both it and the slides to those anxious to enjoy the delights of stereography at a small outlay.

MR. F. W. HINDLEY, who is leaving town for Switzerland, is kind enough to send us a few Convention snap-shots, which include portraits of past, present, and future Presidents of the P. C. U. K., and other prominent Conventioners. We shall preserve Mr. Hindley's excellent mementoes of a very pleasant time. Perhaps no photographic institution is so prolific in its outcome of good fellowship and mutual esteem as the Convention. Long may it continue so to be.

## News and Notes.

A CORRESPONDENT in South Africa states that the American biograph people are up at the front taking photographs of the big naval guns shelling Colenso.

WE are pleased to learn that Mr. C. A. Rudowsky, who has recently been seriously ill, has quite recovered, and is now able to attend to business. We congratulate Mr. Rudowsky, and are sure that his many friends will do likewise.

IT is stated that Mr. Coddington, of the Lick Observatory, discovered a new minor planet by means of a photograph taken with the Croker telescope, and afterwards obtained a series of observations during October and November from which he was able to determine an orbit.

MESSRS. FUERTS BROTHERS' animated photographs of war subjects include the following: Siege-train staff (470 officers and men, composed of the 15th Company, Western and Southern Division Royal Garrison Artillery) embarking on ss. *Tantallon Castle*; Departure of 20th battery Horse Artillery with guns for South Africa.

THE Fifth Annual Exhibition of the Borough Polytechnic Photographic Society will be held at the Institute, 103, Borough-road, S.E., on Wednesday, Thursday, Friday, and Saturday, December 27-30, from 7 to 10.30 p.m. Popular lantern entertainments will be given each evening, and admission to the Institute (three-pence) includes the photographic exhibition, concerts, cinematograph displays, and other entertainments organized in connexion with the Borough Polytechnic Christmas *Conversazione*.

THE following are the results of the Austin-Edwards Monthly Competitions:—Lantern-slide Competition: 3l. cash prize, Mr. J. Kearney, jun., Liverpool, *Under the Hillside* and *A Stormy Sunset*; 2l. cash prize, Mr. E. Bellingham, Blackburn, *Canal, Skipton and View through Archway, Bolton Abbey*; 1l. cash prizes, Mr. W. H. Griffiths, Liverpool, *Ruddy Morn*; Mr. H. C. Leat, Bristol, *The Whistler*; Mr. A. Bainbridge, *First Aid*; Dr. J. W. Ellis, *South Door, Le Folgoet, Finistere*; Mr. G. Shreeve, *Pilot Cutter off to Sea*. Film-negative Competition: The Frens camera given each month for the best negative on an Austin-Edwards film has been secured by Mr. William Baldwin, of Foulridge, for his negative *Worm Out*.

THE following are the results of the Warwick Competition for December:—10l. prize, Miss Edith Haslett, 14, College-gardens, Belfast, *Jacko*; 6l. prize, Mr. J. M. Whitehead, George-street, Alva, N.B., *Dreamy Eyes*; 1l. prizes, Mr. W. J. Brooke, 88, Frodingham-road, Scunthorpe, *Our Sandy*; Mr. E. Cardwell, Minster-street, Reading, *Bolton Castle*; Mrs. W. F. Clarke, 11, Park-terrace, Nottingham, *A Butterfly*; Mrs. Albert Durn, Long-street, Wootton-under-Edge, Gloucester, *Little Sunshine*; Mr. A. E. Davies, 24, July-street, C.-on-M., Manchester, *Port Skiffion*; Mrs. E. D. Girdlestone, 90, Greenfield-road, Harborne, Birmingham, *A Merry Sprite*; Mr. W. Gillans, jun., 4, Ninth-row, Ashington, Morpeth, an interior; Mr. P. Goodchild, The Colonnade, Leamington, *A Gipsy Girl*; Mr. T. Humber, Hazel-dean, Teddington, a portrait; Mr. F. Ingham, Winton House, Sale, Cheshire, an interior; Mr. Dan Jones, White House, Llandegla, Mold, *Feeding Time*; Mr. W. Knox, 380, Cumbernauld-road, Glasgow, *White Wings*; Mr. Elfie Levack, 2, Grantley-terrace, Guildford, a portrait; Mr. W. J. Obree-Smith,

14, Sutherland-avenue, London, W., *Nelley Abbey*; Mr. J. Q. Rumball, 6, St. Leonard's-terrace, Reading, *A Meadow Scene*; Mr. Gustave Servaes, Place du Sablon, Ghent, *Sunset in Winter*; Mr. Nicholas Smirnoff, 32, Welbeck-street, Cavendish-square, W., *Rocks at Folkstone*; Mr. C. S. Tyler, High-street, Earls Colne, Essex, *"Me can play Fiddle"*; Mr. H. Whittlesey, 32, Humber-road, Beeston, Nottingham, *Interior, Winchester Cathedral*; Mr. W. J. Wright, Meerbrook, Thurlow Park-road, West Dulwich, a portrait.

## Patent News.

THE following applications for Patents were made between December 4 and December 9, 1899:—

LENSES.—No. 24,089 "Improvements in Objectives for Photographic and like Purposes." P. RUDOLPH.

FILM AND PLATE-CHANGING.—No. 24,201. "Improvements in or relating to Mechanism for Changing Photographic Plates or Films." C. J. BANNISTER.

PRINT-TRIMMERS.—No. 24,278. "An Improvement in Gauges for Print and Card Trimmers." J. CHRISTIE.

SHUTTERS.—No. 24,319. "Improvements in Photographic Shutters and Apparatus for Calculating the required Duration of Exposure." THE THORNTON-PICKARD MANUFACTURING COMPANY, LTD., and C. G. WOODHEAD.

HALF-TONE SCREENS.—No. 24,468. "Improvements in Screen Gears for Photographic Process Cameras." A. W. PENROSE and H. A. BROWN.

STEREOSCOPES.—No. 24,557. "Improvements in Stereoscopes and in Stereoscopic Slides therefor." A. PUMPHREY.

## Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

December.	Name of Society.	Subject.
27-30 .....	Borough Polytechnic .....	Fifth Annual Exhibition.
28 .....	Oldham .....	Exhibition of Prize Slides.
29 .....	Bristol and West of England ...	{ Technical Control for Pictorial Results. W. Thomas.
29 .....	Croydon Microscopical .....	{ Composition and Selection of Subjects in Pictorial Photography. A. Horsley Hinton.

## ROYAL PHOTOGRAPHIC SOCIETY.

DECEMBER 19.—Photo-mechanical Meeting,—Mr. Chapman Jones, F.I.C., F.C.S., in the chair.

## A SENSITOMETER FOR THREE-COLOUR WORK.

CAPTAIN W. DE W. ABNEY, C.B., R.E., D.C.L., F.R.S., read a paper with the above title, in which he detailed the results of experiments which were themselves the outcome of much previously published work in the same direction. The sensitometer now described differed in some respects from that which he introduced in a paper read at the Camera Club a few years ago, and would, he thought, be more generally available to photographers. It consisted of a disc with arcs of suitable colours, the bands being so proportioned that when the disc was rotated the luminosity of each coloured arc would be the same; to take a photograph of such a rotating disc it would be necessary to use a screen which would cut off such quantities of light from each sector as would make the densities of each ring the same. If one colour was too dense when a certain screen was used, the experimentalist must remember that its complementary colour must be added, or possibly a mixture of two complementary colours where the rings were each of varying density. The luminosities of the colours of the several sectors, taken in the electric arc light, were given as follows: white, 120; yellow, 70; red, 45; green, 32; blue, 16.8; violet, 12.2; black, 2. Photographs were shown of the rotating parti-coloured disc, taken on Cadett's spectrum plate and with the Cadett screen, the densities of the different colour bands being identical. The application of the method to the production of negatives for three-colour work was very fully dealt with, tables and diagrams being given for the facilitation of the production of the necessary screens; the details are of such a nature that they cannot possibly be condensed into summary form, but they will, in due course, be published in the Society's journal, and will be found to be of great practical value to all who are interested in the subject. With some brands of isochromatic plates Captain Abney had failed to get absolutely uniform densities, and his paper concluded with a consideration as to where the sacrifice should be made in such cases, and which colours were most essential to uniformity. The yellows, reds, and whites should, he said, preserve the same densities as closely as possible, and he regarded yellow and white as the most important; in the red negative he would give the greatest attention to red, yellow, and white; in the green, the white and the yellow; but the green itself might vary twenty per cent. in density without material injury to the print; and, in the blue negative, the blue and white should give identical densities.

MR. JAMES CADETT said there was an idea in some quarters that it was not absolutely necessary to take the true sensation curves as a basis for correct work, and that it was possible to make a satisfactory compromise, and he asked whether sufficient allowance could be made in practice to render this idea workable.

Mr. SANGER SHEPHERD spoke in eulogistic terms of Captain Abney's new method of sensitometry, but said he preferred the older plan of working with pot-metal glasses on account of their permanence.

Mr. J. R. GOTZ asked what pigments were used for making the coloured sectors.

Mr. J. C. WARBURG asked how the colours were laid on, and what precautions were taken to ensure the evenness of the coating.

Mr. W. GAMBLE inquired whether printing inks could be used instead of pigments.

Captain ABNEY, replying to the question as to whether compromises were admissible, said some people wished to take violet as a primary, and that in that case no harm would be done; in triple projection compromise was absolutely necessary. Pot-metal glasses would fade in time, like everything else, but not in the short time in which a pigment would fade. He believed, however, that the pigments which he used were fairly permanent. The glass sensitometer was, no doubt, very useful in the hands of Mr. Shepherd, but the object of the paper was to describe a method which might be more generally useful. It was always possible to get a pure zinc white, an emerald green, a chromium yellow, a French blue, and a vermilion, and these would provide all that was wanted for the sensitometer. The colours could be laid on brutally, with a brush and very little size, and there was no difficulty in getting an even coating. Printing inks could be used, but the glossy surface must be removed or avoided.

#### COMING EVENTS.

January 2, Lantern Evening, "Round about the Matterhorn and the Aletsch Glacier," by Mr. Henry Speyer. January 9, Ordinary Meeting, "Toning with Salts of Copper," by Mr. W. B. Ferguson.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 14.—Mr. Lewis Medland in the chair.

Mr. S. H. FRY showed a sheet of colour printings done on the Orloff press. This system ensures perfect registration, as the whole of the three or four colour impressions are laid upon the paper at once. The illustrations shown were trade labels, and were printed at the rate of 1000 per hour.

Mr. T. E. FRESHWATER passed round a number of prints received from India, showing the terrible destructive power of the cyclone which recently passed over Darjeeling. The railways presented a most woe-begone appearance, and the havoc wrought amongst the dwellings was no less complete.

A piece of glass for use as a focusing screen, prepared by Mr. James Wheeler's reticulation process, was passed round for examination. The glass is very translucent, but opinions differed as to the fineness of the grain. It was observed that an ordinary piece of ground glass could be more easily finely ground than a piece of plain glass. The skin of the glass was already removed, and friction with fine washed emery powder would give to it a very delicate grain. Thin plate glass also was easily worked, there being a very slight skin.

Mr. FRESHWATER gave some interesting notes of a naturalist in the north of London. He brought up a case of about a hundred butterflies, moths, and other specimens collected in his garden and the vicinity during the past summer. By means of the lantern, photographs of many of the insects were shown on the screen. Mr. Freshwater has succeeded in acclimatising to the district more than one variety of butterfly and moth by a system of nursing and feeding. He did not anticipate incurring the ill feelings of his neighbours, as most of them fed on wild growths and did little harm to cultivated plants. He also handed round some specimens of whole insects mounted in balsam by a clever and experienced naturalist, which looked very well on the screen, some being stained for the purpose.

The meeting was also given an opportunity of seeing pictures of the mounds turned up by ants, peculiar and extensive structures, many of which in the Transvaal are used as cover.

The CHAIRMAN added that they burned splendidly, and that, when he was in South Africa, he often cooked his food in a hole scooped out of the mound.

Mr. CHERRY KEARTON's very fine photograph of a spider, web and nest, was shown.

Mr. FRESHWATER said the photographs were taken by Ross's portable five-inch lens, also three-inch, two-inch, and the Zeiss's planar lens of one and three-eighth inch. Some were done with orthochromatic plates, but the majority on the Paget XXX plate.

Richmond Camera Club.—December 11.—Mr. A. C. BALDWIN, on behalf of the Paget Prize Plate Company, gave a demonstration of the capabilities of the Gravura paper, opals, and lantern plates. He exposed and developed prints on the paper and opals, and made three lantern slides while the room was sufficiently well lighted by two gas jets to enable every operation to be easily seen by the whole of the members present. Mr. Baldwin made his exposures by means of burning magnesium ribbon, the lengths required to produce black, brown, and red tones being in the proportion of 1, 6, and 8 respectively. For all tones but black, the developer was diluted and a small quantity of a ten per cent. solution of carbonate of ammonia added, the amount depending on the amount of exposure the paper, &c., has received. Exposures were made for each of the three tones, half an inch of magnesium ribbon being burnt at about thirty inches from the printing frame for black, three inches for brown, and four inches for red. The results in every case were satisfactory, and proved that it was perfectly easy to work in an ordinary room lighted with gas without fear of fogging the prints.

West London Photographic Society.—The second of the series of Begginners' Meetings was held on the 15th. Mr. G. F. BLACKMORE lectured on

#### EXPOSURE AND DEVELOPMENT,

in the course of which he advised the novice to choose a slow plate, and stick to it until he had completely mastered it, using the developer recommended

by the makers, but starting with only half the amount of alkali. He emphasised the necessity of fairly accurate exposures, and strongly commended Wynne's meter as being of great service in that direction.

Liverpool Amateur Photographic Association.—December 16.—Mr. FRED. A. SCHIERWATER gave a lecture on

#### THE VALLEY OF THE WYE.

Mr. J. H. Welch (Vice-President) presided. The lecturer was one of the fourteen members of the Association who at Easter had four days' holiday in the district, and gave the experiences of the party in a very racy, anecdotal fashion, keeping his hearers thoroughly interested from start to finish. By means of a number of slides, Mr. Schierwater took the audience all over the district travelled by the holiday-makers, starting from Monmouth, and visiting Symonds Yat, Ross, Redbrook, Tintern Abbey, Chepstow, Forest of Dean, and Raglan Castle. The slides reflected great credit on the makers, but special praise should be awarded to Mr. F. Anyon for his sheep studies in the Forest of Dean.

#### FORTHCOMING EXHIBITIONS.

1899.

Dec. 22-Jan. 1900 ... Huddersfield (Invitation). W. A. Beevers, Cloth Hall-street, Huddersfield.

„ 27-30 ..... Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.

1900.

January 29-31..... Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.

February 10-24 ..... Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.

March ..... South London Photographic Society.

April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### ORTOL.

To the EDITORS.

GENTLEMEN,—Your Berlin correspondent (Hendrich Sapt) is certainly an industrious man, but he omits to say how many assistants he has to produce his nearly 10,000 plates, films, prints, &c., and he also omits their size. Perhaps they are postage-stamp size, nine on a quarter-plate. May I also assume that his ignorance of the English language, and his peculiar method of expressing himself, is also responsible for the evident misprint or mistake, for he goes on to say, "and all this done with one eight-ounces of developer." As the metric system is in vogue on the Continent, it is evident he means eight litres of developer, or else that he has used eight-ounce bottles of ortol, this being most likely.

About fourteen days ago I purchased a one-ounce bottle of ortol (2s. 6d.). It certainly seems to be a veritable widow's cruise of oil. The used developer really seems to act better than one fresh mixed. Certainly for plates I cannot see any difference, and for bromide prints half new and half old, with a little hydroquinone added, the results are all that bromide paper will give, i.e., clean whites and good blacks, with the usual gradation.

Referring to "C. E. F. N." and "Novice" in your issue of December 8, I regret I did not see what "Novice" describes as your last issue, i.e., December 1, but in an earlier issue I noticed the commencement of an article by Mr. Welford on ortol, and it seemed to me he had reduced it to simplicity itself. The ortol was made up to 60 ounces or parts, the carbonate to 30, the sulphite to 15, and as you were to take 1 ounce of ortol or 1 part, ½ ounce of carbonate or ½ part, ¼ ounce of sulphite or ¼ part, it became evident that the three bottles of solutions all became empty or used up at the same moment, thus a very excellent formula. Regarding bromide a ten per cent. solution was ordered, and five to ten drops of this to each ounce of developer, and if pure whites and blacks are required with bromide paper, ten drops per ounce of developer is not any too much.

Doubtless both your correspondents are aware that parts may mean grains, ounces, pounds, or millimetres, and it is evident Mr. Welford, in speaking of a part, means the amount of ortol one is about to use, and

then half that amount of carbonate, and a quarter that amount of sulphite; at least, that is the meaning I attach to his instructions.—I am, yours, &c.,  
 ARCHER CLARKE.  
 63, St. John's-hill, Clapham Junction, S.W., December 12, 1899.

### THE SOUTHSEA PHOTOGRAPHIC SOCIETY AND THE WAR FUND.

To the Editors.

GENTLEMEN,—I have, no doubt you will be pleased to hear that I have been able to hand over a cheque for 45*l.* to the War Fund for the widows and orphans, as a result of the lecture which was organized by the Southsea Amateur Photographic Society, on "The Real Dickens Land," by Mr. H. Snowden Ward, at the Town Hall, Portsmouth, on Tuesday, December 12. The entire affair was a great success, and the reason I am able to hand over such a substantial sum is because a large amount of the expenses were guaranteed, and paid, by the members of the Society.

I trust other and even more flourishing societies will follow our example, and see what they can do to help so worthy and necessary a cause.—I am, yours, &c.,  
 F. J. MORTIMER, Hon. Sec.

10, Ordnance Row, Portsea, December 16, 1899.

[We congratulate the Southsea Society on their successful endeavour to help a cause that appeals to all hearts, and we hope to see their good example followed by other societies.—EDS.]

### DR. VON ROHR'S THEORY AND HISTORY OF LENSES.

To the Editors.

GENTLEMEN,—In your last number I noticed Mr. W. Curry's protest against my work as far as the late Mr. John Henry Dallmeyer is concerned. I was much interested to hear of a fellow worker of Mr. Dallmeyer's, and I very well understand his wish to record the fact that Mr. J. H. Dallmeyer was a very kind employer. But I am at a loss to understand what this has to do with my criticism as to his being an original thinker in optical matters.

I am, of course, unaware whether Mr. W. Curry understands German or not, but as long as he does not tell me the contrary, I shall think that there is some misunderstanding, due to imperfect translation. One sentence seems to have met with his special discontent (Germ. Edit. p. 218), and, to enable the public to form their own idea on this representation, I give here a translation, as exact as I am able.

"He hardly seems to have been gifted with a specially great originality of invention; in this, and especially in experimenting, he was behind T. Grubb; but, on the other hand, an unmistakable endeavour to retrace the historical development of a type or of a theory distinguishes him from among the opticians of his adopted country."

This comparison between Mr. T. Grubb and Mr. J. H. Dallmeyer could perhaps be considered as being clear enough, but I do not hesitate to declare that in using the term "Optiker" (opticians) I did not mean trading opticians only, but also men who wrote papers on optical matters.

Now, I certainly attribute the greater originality to Mr. T. Grubb, "a man," to use Mr. W. Curry's own words, "whose work still lives, and the influence of whose work will always live." Further, I cannot see any fault in giving this judgment, which I honestly believe to be correct.

Mr. W. Curry's further judgment is given in such general terms that it is impossible for me to enter into details, but there is one line which I think it my duty to answer. It runs thus: "Where he obtained his information from, and his motive, if any, are subjects best known to Dr. von Rohr himself." Now, as to the motive, I intended to write the history of photo-optics, after careful perusal of all printed sources available to me. As regards the sources where I obtained my information from, I gave them in every instance, and I am not aware that my statements are inconsistent with these sources.—I am, yours, &c.,

Jena, December 18, 1899.

DR. VON ROHR.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS AND PAINTING REGISTERED:—

Anty, Ltd., 20, Front-street, Tynemouth.—Photograph of members of Peasey Park football team and committee.

H. Nickson, West street, Fleetwood.—Photograph of park and tennis ground, Fleetwood. Photograph of depa ture of fishing fleet, Fleetwood. Photograph of pleasure boats and lower lighthouse, Fleetwood. Photograph of departure of ss. "Mona's Queen" from Fleetwood to Isle of Man.

M. W. Swiney, Hartington House, Herne Bay.—Painting of Notre Dame du Saints Rosaire.

PAUPER.—Your question is scarcely one of a photographic character. A pharmaceutical chemist or medical man might assist you.

OMILOUSE and C. K. T. do not send us their names and addresses. Hence, according to our rules, their queries remain unanswered.

INVESTIGATOR.—The institution which would answer your purposes the nearest would be the Polytechnic, Regent-street, London, W., where tuition is given privately or in class.

FIXING BATH.—WARDER. Two ounces of hypo to the pint of water, with ten minutes' immersion, is too weak for the paper you are employing. Increase the hypo to four ounces, and the time to a quarter of an hour at least for perfect fixation.

BROKEN PLATES.—J. H. W. It is no use your writing to the makers of the plates. Your remedy is against the one who sold them to you. Probably they were all right when they left the factory. Any how, the one who supplied them to you is the one to whom you must complain.

LIVING VANS.—PHOTOGRAPHER says: "Would you kindly inform me where I could hire a living van from, suitable for a tour? I saw in a paper some time ago the name of a firm in Yorkshire, but unfortunately did not make a note."—In reply: We cannot find a reference to the Yorkshire firm; perhaps some reader will supply the desired information.

TINTYPES.—A. BOWER asks: "What are 'tintypes' and how are they produced, and what apparatus is necessary, and its cost?"—Tintypes are what are more generally known, now, as ferrotypes, and they are produced in the same way, as are also glass positives. The apparatus necessary is only an ordinary camera and lens. The cost will, of course, depend upon size and quality.

INTENSIFICATION.—AJAX says: "I have a valuable negative which has been intensified by Monckhoven's process, but is still rather too thin to give pure whites in the prints. Shall I get increased density if I repeat the intensifying process, and can it be done without risk of damage to the negative?"—Yes, the intensification can be repeated. There need be no risk if the operations are carefully carried out.

FROZEN WATER PIPES.—Mr. T. Everitt Innes writes: "Noticing your recent advice on keeping pipes from freezing, I venture to send the following method (which I don't think is generally known) of thawing outside sink pipes, for those who have been unfortunate enough to neglect your warning. It is simply to place a newspaper or bunch of straw round the pipe and set fire to it. I can guarantee that this is far better than some people's way of putting a red-hot poker up it and melting the lead."

THIN NEGATIVES.—H. CROSS sends a thin negative and says it was a long time developing, and, in the end, had not sufficient density. He asks if it is to undue exposure that the thinness is due?—The negative is fully exposed, but the slowness of development, and its thinness, is probably due to the coldness of the developer and the coldness of the room in which the plate was developed. Keep the solutions up to 60° or 65°, and the dark room at a similar temperature, and all will go well, we have little doubt.

PATENTING AN INVENTION.—PATENT says: "Will you tell me how I can patent an invention? Could I do it without coming to town and without applying to any agent? If so, kindly state how I am to proceed in the matter, especially as I wish merely to protect for about one year. Could I apply to the Patent Office direct to patent it, and would they give me all information free?"—In reply: You need not come to town. The necessary forms can be obtained at the Patent Office, Southampton-buildings, Chancery-lane, London, W.C., and you can obtain nine months' provisional protection for your invention for 1*l.* without employing an agent.

SPOTS ON PRINTS.—SPOTTED PRINT writes: "I enclose a print, which has come up spotted, after it has been finished ten days, some of the others done at the same time have come up the same way. I would be very glad if you could tell me the cause, and how to avoid it in future. I have written the particulars on the back of the print as to toning and washing."—It is impossible to say positively the cause of the spots; but we have little doubt they have their origin in insufficient fixation, for we note that you make the fixing one part of hyposulphite of soda to fifteen parts of water. This is far too weak for the time you give. Use a bath of three times that strength, and we surmise you will not be troubled with the spots.

BLUE PRINTS ON FERRO-PRUSSIAN PAPER.—A. C. says: "1. It is desired to write on these with an ink that will stand the subsequent bleaching; can you state one? Higgins's waterproof ink is not acid or alkali-proof, 2. What will bleach out the blue on above prints and not affect the ink, so that the new matter can be copied in the camera?"—1. Try lithographic chalk, that will probably answer your purpose. 2. Ferro-prussian papers are not all prepared alike, and you do not say how you have prepared that you wish to bleach. In our issue for May 12, and continued weekly, were a series of articles on the iron processes, which gives a collection of all that has been published on them. If you consult them, you will see how to deal with papers according to different formulae.

MINIATURE PHOTOGRAPHS.—VELOX says: "Can you inform me how the miniature photographs are taken, I mean same as taken by Messrs. Seaman? What is the arrangement of camera back or slide whereby a number of different sitters can be taken on the same plate; and also if different sizes could be taken on same plate? Can you also give me any particulars of a special printing frame for this class of work?"—Messrs. Seaman & Sons use their patented printing frame, which they also supply to the public. There are several ways by which a number of portraits can be taken on the same plate—such, for example, having several small lenses on the camera—having a repeating back on the camera, with several repeats; or, more commonly, by a combination of both methods.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900.

EDITED BY THOMAS BEDDING, F.R.P.S.

What some readers think of the book:—

- "Even better than its predecessors."
- "A remarkable publication."
- "Full of valuable information."
- "Useful and portly."
- "A lot of it—looks all right."
- "Ever welcome."
- "Most interesting and instructive."
- "I cannot understand how, in such a short time, you can complete such a stupendous work."
- "Much to enjoy in the present ALMANAC."
- "I daily enjoy the admirable ALMANAC."
- "I see several new features, whilst retaining the general familiar appearance, which if much altered would give the impression of another book. Good old friends are best kept."
- "The most wonderful publication for a shilling that I have ever seen. You deserve all the praise words can afford for so useful a work."
- "The ALMANAC is the best thing of its kind."
- "A work of monumental capacity."

A few opinions of the Press:—

- "Well up to date. . . . an indispensable adjunct to the outfit of the photographer." *Morning Advertiser.*
- "Welcomed by thousands of photographers, trade and amateur, who have come to regard it as indispensable." *Newcastle Daily Journal.*
- "Welcome both to professional and amateur photographers." *Manchester Guardian.*
- "No photographer ought to be without it." *Shrewsbury Chronicle.*
- "Almost a reference library in itself." *British and Colonial Druggist.*
- "A work of which specialists have long known the value." *Glasgow Weekly Herald.*
- "A useful volume which no photographer should be without." *Kent Argus.*
- "Crammed full of all the very latest information." *Invention.*
- "A massive and remarkably cheap volume." *Birmingham Daily Gazette.*
- "There is nothing like it in the photographic world that we know of, either for bulk, or variety, or merit." *Western Mail.*
- "A very bulky volume at a very moderate price." *Gloucester Journal.*
- "The whole book is thoroughly practical." *Horse and Hound.*
- "Stupendous." *The Stage.*
- "This wonderful almanac." *Pharmaceutical Journal.*
- "An absolute mine of information. . . . ought to find a place in every photographic studio." *Nature.*

## EX CATHEDRA.

By the courtesy of a correspondent, we have received a half-tone photograph of the form of certificate or diploma which the Photographers' Association of America awards to exhibitors at its annual Conventions. The nineteenth gathering of the kind was held this year at Celeron. The design of the certificate is very elaborate. A graceful half-draped figure is holding a crown of laurel over the head of a kneeling young man in tourist's garb. There is, apparently, a bit of Moorish architecture in the background, and surrounding the certificate, which is signed by the President and Secretary, there are the seal, a camera, printing frames, pestle and mortar, dishes, graduates, and so forth, while at the right-hand side of the picture some winged, cherub-looking young persons are floating about amidst a shower of mounted prints, &c. Like Todger's, the P. A. of A. can do it. We wonder if the British Convention will ever rise to such great heights?

WE have had submitted to us the reproduction of a print made from a negative taken in the "Al Vista" panoramic camera which is manufactured by the Multiscope and Film Company, of Burlington, Wis., U.S.A. It is a view of Niagara Falls, showing both falls, from Old Clifton House to the railing of the Suspension Bridge. The size of the picture is twelve inches by four inches, and, as may be imagined, a very wide angle of view is subtended. We understand that during the coming season cheap rollable film cameras for panoramic photography will be placed on the British market, and no doubt they will attract considerable attention.

\* \* \*

MR. T. C. PHYTHIAN, of Newlands, Cheetham Hill, Manchester, writes: "I have observed your article in the ALMANAC on stereoscopic photography, and am aware that you are specially interested in the subject. As you may not have seen a similar slide to those I have been producing for some time past, I take the liberty of sending a few for your inspection, thinking they may be of interest." We thank Mr. Phythian for his courtesy. The style of binocular slide which he sends us is not novel to us; we possess several mounted in a similar way, produced by the late W. Harding Warner. However, to describe the slides in question: Mr. Phythian's binocular views measure, each half,  $2\frac{3}{4} \times 3\frac{3}{4}$ , and they are attached to mounts  $6\frac{3}{4} \times 4\frac{1}{2}$ , behind green card "mats," or cut-out openings. This is a very effective way of mounting stereo slides. Mr. Phythian also possesses a stereoscope, working like a camera, into which thirty or forty slides are put at once, and racked forward, the front one dropping through a slot, and so on, and he describes this as a very pleasant way of looking at the pictures.

\* \* \*

SOME attention is being excited by a process for reproducing paintings, which is said to be in use just now in the German picture galleries. We are told that "it differs in its method from any heretofore employed, as it enables the reproducing artists not only to create true facsimiles of originals by means of photography and steel etching, but also to produce the depth of colour and peculiarities of manner of each master. The process, while an intricate and costly one, is not patented, but the details are kept a strict secret. After the original paintings have been photographed with the aid of special cameras and plates, the photographs are transferred to steel plates, the surface of which, by some peculiar treatment, has been prepared to receive the impressions from the negative. The outline is thus obtained upon the steel with great exactitude. The colours, as true to the original painting in the distribution of light and shade as manipulation of the brushes of eminent artists can make them, have been reproduced on the photographic copy first obtained, and the complex colour picture thus created is transferred to as many lithographic stones as there are colours represented in the picture, from which impressions are taken on presses worked by hand. The greatest care is used in the choice of subjects for reproduction." On these very meagre details it is impossible to offer an opinion or criticism of this wonderful process; but it appears to have a resemblance in some respects to a method of reproduction introduced some time ago by Mr. Henkner, though that gentleman, if we remember aright, was content with monochrome. The above process reads like a mixture of intaglio etching and chromo-lithography.

ACCORDING to Dr. Gustave Michaud, in the *Scientific American*, a Boston firm sells, under the name, "X-ray camera," an apparatus which apparently enables an object to be seen through any opaque substance. But the X rays have nothing whatever to do with the phenomenon, which is really produced by a set of four hidden mirrors that conduct the light around the opaque object. The Doctor recently devised and constructed a little apparatus, which, he says, is just as deceitful as the X ray camera, but which is more readily made, and gives results by far more astonishing for spectators who have not been told the secret of its construction. It apparently reproduces instantaneously and neatly the interior of the human body, giving to every organ its natural colour. The whole operation is performed under the eyes of the bewildered sitter, who watches the X-rays in what seems to be the act of drawing and painting before his eyes his vital organs. Dr. Michaud adds that the apparatus looks like the objective tube of a camera, with the plate on which the image is to be produced in full sight of every one. The apparatus is placed opposite the person whose viscera are to be photographed, and, to heighten the effect, a lamp may be solemnly placed behind the sitter. The operator invites every one to look at the white sheet of paper, and presses the rubber bulb of the shutter. A coloured image appears instantaneously on the paper. The lungs are of a bright red colour, the heart is darker, the veins are blue, the stomach and intestines are of a greenish tint, other parts of the body paint themselves in black on the white paper. This sudden apparition generally startles the sitter, but a few remarks on the healthy looks of his lungs will place him at his ease. The photograph is taken out of the apparatus and passed round among the spectators.

\* \* \*

THESE interesting results are brought about in the following simple manner: Before the experiment the sheet of paper is treated as follows; it is pinned over any anatomical drawing, showing the position of the principal thoracic and abdominal organs. If the sheet of paper is not too thick, the drawing can be seen through it. The space occupied by the lungs is then painted with a diluted solution of sulphocyanide of potassium. A more concentrated solution of the same salt is used to fill the space outlined by the heart and principal arteries. A few big veins are painted with a solution of ferrocyanide of potassium. A more diluted solution of the same salt is used for the stomach and a few intestinal folds. The rest of the body is uniformly painted with a concentrated solution of tannin. When the paper is dry, the drawing is absolutely invisible, for all the above-named solutions are colourless. The sheet of paper is now ready for use in the apparatus. The objective tube does not contain any lens, but merely a small atomiser filled with a solution of ferric chloride. When pressed, the rubber bulb sends air, not, as every spectator believes, into a pneumatic shutter, but into the atomiser. As a result, a fine and invisible spray of the perchloride of iron solution reaches for a moment the sheet of paper. Dr. Michaud points out that the reactions between ferric salts on one side, sulphocyanide of potassium, ferrocyanide of potassium, and tannin on the other side, are among the most sensitive of analytical tests, owing to the extraordinary intensity of the red, blue, and black colours which originate in these reactions. Hence the instantaneous production of the coloured picture.

## A SEASONABLE BUSINESS HINT.

PROFESSIONAL photographers—we are more especially alluding to portraitists—are not having a busy time of it just now; nor is there any great prospect of a material improvement for the next two or three months. But could not many photographers do more business during the winter months by making a greater feature of winter portraits, that is, pictures taken with wintry surroundings? In some countries—Canada, the States, and in Russia—the winter is turned to very profitable account by portrait photographers taking pictures of sitters clad in their furs, with accessories covered with snow, and a background to correspond. In the countries named they are sure of a winter, and they prepare for it. Here we are not sure of one, and few sitters would care to be taken with snowy surroundings if we experienced no real winter; yet there is no reason why artists here should not be prepared to profitably avail themselves of it should a hard one set in.

Some have had the idea in mind, for last week we had to reply in the Correspondence column to a firm in the country as to whether we should recommend them to make a feature of winter portraits, &c. We should say that all photographers would do well to at least make preparations on the chance of profiting by a severe winter, even though we have none, because it can be done with little or no outlay, and with but little trouble. Already flocks of gulls are to be seen at London, Blackfriars, and Westminster Bridges, and this is considered by many of the "weatherwise" to portend a hard and prolonged winter.

As we have just intimated, to be prepared beforehand involves very little cost and trouble; it may therefore be well to give a few hints on the subject. First, we must have a suitable background, and any old outdoor one may easily be made to answer the purpose, even if worn out for other work. Supposing it is a sunny landscape, for example, we take a white crayon, or piece of chalk, and trace over the *upper* surface only of the branches of the trees, rocks, prominences, or anything else where snow would have lodged had the scene been real. In this way an effective background is easily provided, but it may be mentioned that the crayon work should not be too pronounced, or it will become obtrusive in the picture. With regard to accessories, rustic stiles, steps, balustrades, and the like should have some cotton-wool or wadding, such as is sold by the drapers in sheets, tacked on their upper surfaces to represent fallen snow, which it will do very effectively. A few sheets of white wadding, stitched on to a sheet or piece of canvas, will complete the arrangement so far as the ground is concerned. It will now be seen that the whole thing involves very little trouble and less expense, as the chalk can be readily wiped off the background, leaving it as at first.

The next thing is the specimens. It goes without saying that they should be appropriately attired. A sitter in summer attire, or in evening dress, with outdoor winter surroundings, would, of course, be highly incongruous, but we have frequently seen equal incongruities, and from good houses, in which sitters, clad in furs and heavy costumes, have been posed before brightly lighted sunny backgrounds and surroundings, which were obviously only appropriate to summer costumes. Furs and fur-trimmed costumes lend considerable scope to the photographer, as they tell well in the pictures, and should be freely utilised in specimens of winter portraits.

The introduction of a pair of skates will also add to the effect of the winter portrait.

In many of the Canadian, American, and Russian pictures we have seen, the appearance of falling snow has been depicted, i.e., flakes of snow falling thickly on and around the sitter. This, it need not be said, is done by "faking" the negative; but it is easily done by splashing on or distributing over the finished negative an opaque pigment. One of the best methods, perhaps, is to take Chinese white, as sold in tubes by the artists' colourmen, and thin it with water on a palette, then take an ordinary toothbrush and touch the ends of the bristles on the palette so as to just take up a little of the pigment, and then, in front of the negative, pass, say, the back of a knife across the bristles so as to flick the colour on to the negative in fine particles. Before doing this it is desirable to varnish the negative, as then, if the result is not satisfactory, the pigment can be cleaned off and a fresh essay made; whereas, if it were not varnished, that could not be effectually done.

In some of the pictures of this kind we have seen, the snow has been depicted as falling every where except before the face of the subject, which gives the picture a highly incongruous appearance. Yet, of course, the portrait is the main feature to be considered in the picture. This incongruity may, however, be avoided, and yet the unobstructed portrait retained, in the following way: Let the sitter hold a small umbrella over the head, though not too forward so as to obstruct the light. In this way the face will not be represented free from the snow flakes and at the same time be free from incongruity. The umbrella, which may be a stock one, should be *thinly* covered with the white wadding, stitched on, so as to be in unison generally with the picture.

With the above hints any one with ordinary ingenuity can quickly extemporise every requisite for producing portraits that prove so remunerative in those countries where there is a certainty of having a real winter, such as we experience at times, though uncertain ones.

---

**The City and Art.**—The Corporation of the City is doing its best to encourage art. At its last meeting the Court of Common Council granted the use of the Art Gallery for a time for the display and sale of works of art by Royal Academicians and others in aid of the Mansion House Transvaal War Funds. It was also referred to the Library Committee to arrange for an Exhibition in the Art Gallery in 1901 of the works of Velasquez and Fortuny. The Court also resolved to co-operate with the London County Council in the endeavour to secure the preservation, on account of its historic associations, of the house, No. 17, Fleet-street, and to contribute 2500*l.* towards the purchase of the freehold, provided that the decorated room on the first floor be preserved for the public benefit. It remains to be seen whether the vandalistic London County Council will agree with this. If this old historic room is destroyed, it will certainly not be the fault of the City Corporation; it has more consideration for art and antiquity than has the L.C.C.

---

**Does Backing a Plate render a Longer Exposure Necessary?**—An interesting point was raised the other night as to whether backing the plate slowed it. The discussion arose through a remark made by Mr. Thomas Fall at a previous meeting to the effect that it did. This is not the first time that the subject has been mooted, and different opinions on it expressed, without out any definite conclusion being arrived at. A series of carefully conducted comparative experiments to settle the question would be valuable. Of course, the results, to be conclusive, should be gauged by some such method as that of Hurter & Driffield. Who will undertake the work?

**Permanent Albumen Prints.**—A fortnight back we quoted from an American contemporary an article with the above heading by Mr. D. Bachrach, which we commend to our readers. The name of Bachrach is known here as well as in the States as being one of the oldest amongst practical photographers, and anything appearing over it may be relied upon. On many occasions, when writing on the permanence of the old silver prints, we have pointed out that much of their permanence is due to the fact that very strong baths were used, and that the image was not only on the surface of the paper, but in its body; also that the old prints were more thoroughly fixed than is the case with the majority of the modern ones. In Mr. Bachrach's method the albumen paper is not merely floated on a sixty-grain bath, but is immersed in it for the time usually given in floating. It is then printed from the back, and the result is, practically, a plain paper print. As Mr. Bachrach says, "the print is really all through the body of the paper." Another point in Mr. Bachrach's method is the fixing of the prints. He uses the fixing solution about double the strength of that usually employed in this country, and allows "fully twenty minutes' immersion therein." Prints carefully produced under these conditions, and printed from strong negatives, we have no hesitation in saying, will prove as permanent as those old ones that have stood the test of time for thirty years and more.

**X Rays in Court.**—Before now, photographs taken by the X rays have been produced as evidence in a law court in this country. Recently they were shown, as a witness, in a case in Paris when Maitre Labori, the celebrated counsel for Captain Dreyfus, prosecuted his action against the *Libre Parole* newspaper for defamation in publishing reports pretending that the outrage was a sham, and that Maitre Labori had not been wounded by a revolver at all. According to the reports of the case in the *Débats* and the *Temps*, the operator who took radiographs of the bullet imbedded in the muscles of the back produced them in evidence. There is no question that these photographs had great weight with the Court, for the *Libre Parole* was condemned to a fine of 2000 francs, and the verdict ordered to be advertised, at the expense of the *Parole*, in forty Parisian journals and 200 provincial ones, the cost of each insertion, however, to be limited to 100 francs each. In face of the radiographs showing the bullets imbedded in the muscles of the back, it would seem useless to attempt to prove that the man was not shot at all, so the paper allowed the case to go by default.

**Another Meteorological Observatory.**—We read that a meteorological observatory is to be established at the summit of the great cathedral spire, Ulm, Germany. This spire reaches an elevation of 528 feet. Although the spire was only completed in 1890, the church itself was commenced some 500 years ago. There is certainly some novelty in the establishment of an observatory on the spire of a cathedral, and it almost leads one to speculate as to whether one on the top of St. Paul's would aid our Meteorological Office in making more accurate daily forecasts issued by it of the weather to be expected in London from day to day than it does at present. If our daily forecasts were more accurate and reliable, they would often be of great value to photographers.

**Gas Cylinders.**—The lantern season is now in full swing, and we see that the District Railway are repeating the same notices they issued last year to the effect that cylinders of compressed gases will not be accepted as passengers' luggage, or otherwise, nor will they be "admitted for any purpose on the Company's premises." The North London Railway have also reposted their notices that the cylinders will not be conveyed as passengers' luggage. They, however, will carry them under certain conditions, "which may be obtained at the time of booking." What they may be we are not aware, as we have not had occasion to book any by that line, and, from the wording of the notices, the conditions, it would seem, are not to be had at any other time. Would it not be better if this Company had stated on their notices what the conditions are, so that

would-be senders could know and comply with them before they tender them at the booking offices? However, we have an idea that both these Companies do convey cylinders of compressed gases, but then they generally travel in handbags or the like with the passenger.

**Photographing Gulls on the Wing.**—Photographers resident in London need not make a pilgrimage to the seaside to obtain photographs of seagulls while they are on the wing. Just now they have only to pay a visit to, say, London, Westminster, or the intervening bridges, and they will find flocks of them hovering about on their annual visit to the metropolis. Unfortunately the light is not favourable at this time of the year for rapid exposures, but there is no reason why some successful pictures should not be obtained on a fine day. Gulls are not so difficult to photograph as some may surmise, for, though swift of flight, there are times when, while in mid air, they remain almost stationary, and that is the time to wait for. With a lens with wide aperture, rapid plates, and not too quick a shutter, some tolerably good pictures of the birds may be secured. Very good photographs have been obtained of gulls on the Thames.

#### THE PHOTOGRAPHIC DEPARTMENT OF THE VIENNA POLICE.

[Translated from the *Photographische Correspondenz*.]

A new department has recently been organized in connexion with the Vienna Police Service, to which the name of "Identification Office" (*Erkennungs Amt*) has been given. It is allotted two duties: The measurement of individuals, or anthropometry, and photographic portraiture as an aid to identification.

The Identification Office is located at the prison in the Theobaldgasse, Section VI. of the city.

The anthropometrical department consists of a class room where special lectures are given in the art of measurement, and adjoining it is a large hall where malefactors are measured. The hall is likewise used for the storage of the measurement charts and the photographs.

The hall has been arranged similarly to that of the Paris establishment, which is under the direction of M. Alphonse Bertillon, whose father organized the system of judicial photography. The measuring instruments were exhibited to the public at the Jubilee Exhibition held the previous year.

The photographic department comprises a studio, furnished with two sets of apparatus, where the photographs are taken in two positions—profile and full-face. Next the studio is the dark room, adjoining which are the enlarging and other subsidiary rooms. Printing is done out of doors.

The first department undertakes the measurement of individuals and their description, for purposes of identification.

The second department is devoted to portraiture and record photography and to other auxiliary legal purposes.

Nothing of great practical importance can yet be recorded concerning the new department, as it has only just commenced operations, and further development seems desirable, but a few points will illustrate the manner in which the department may become of service to those who have charge of the public safety.

If an inquiry has to be made, certain facts must be recorded in all cases. Be it theft, robbery, murder, arson, or any other offence, the photographer is called upon to take certain photographs, and it is his duty to make the best use of his knowledge in assisting the official by the photographs he takes.

On November 1, 1899, the head of the Imperial Police also opened a Police Museum, where all instruments of crime and photographs of facts relating thereto are sent.

The following practical examples will show how the service is carried on:—

A parcel of American bank notes was handed in at an American post office, and contained a sum of \$75,000. When it arrived at its destination, the recipient noticed that \$30,000 had been abstracted. The officials who had charge of the case could not discover any clue to help them in their inquiries, and the thief would not have been discovered but for the intervention of an expert official of the Identification Office. This official, upon examining the parcel, found that three seals upon one of

the wrappers had been broken, and that one of these had been made good by pressure with the thumb. As he was acquainted with the methods of identification, he decided to follow this clue. He obtained through the head of each department a wax impression of the right thumb of each person through whose hands the pilfered parcel had passed. By his desire the names were withheld. The impressions were merely numbered, and the corresponding names were only known to the authorities. The wax impressions numbered seven. They were handed to the photographer with instructions to make enlargements from them of a certain definite size. The impression of the thumb upon the seal was also enlarged to the same standard.

The enlarged photographs were then compared, and five were at once rejected as having no resemblance whatever to the impression upon the seal. The sixth showed a slight similarity, but the seventh corresponded with mathematical exactness, and this justified the supposition that the packet had been resealed by the owner of that particular thumb.

In cases of footprints in dust or sand, these should be photographed before any measurements or impressions are made.

Another task of the Identification Office is to determine whether hair, such as may be found, for instance, in the hands of murdered persons, is that of a male or female. In order to demonstrate this by photography, a microscopic examination should be of the greatest value. Also for demonstrating the difference between the hair of men and animals, and for its graphic representation, it should be desirable to photograph the hair of men, dogs, horses, cats, oxen, goats, &c., and make suitable, characteristic enlargements for comparison in case of need.]

A very important item for comparison is blood. A prisoner declared that the blood on an axe which he had used was that of a slaughtered goat. The comparative photographs, made with the aid of the microscope, showed clearly that such was not the case, as the corpuscles of human blood, under the same magnification, appear to be much larger than that of the goat. By means of the microscope, objects may be measured within  $\frac{1}{1000}$  mm. A still more interesting fact is the possibility of determining by means of photography whether an unfortunate person has lost his life by fire or by an antecedent crime.

Apart from the apparatus, a certain routine must be observed in making these photo-micrographs. It is much easier to demonstrate a forgery. For, example, an account had been falsified by changing £. 300 to £. 560. Photographs from the front and back, and by artificial lighting, enlarged to 100 diameters, demonstrated the falsification, as the negative was more dense where the erasure had been made, owing to the transmission of more light. The figures also were uneven in appearance, being more intense where the pen had passed twice, and lighter where the ink had only been used once.

In the department of Public Safety numberless instances could be cited where technical knowledge and a high degree of personal acuteness and cold-blooded impartiality are displayed. It is still fresh in our memories what a deplorable part M. Alphonse Bertillon, the head of the Anthropometrical Service of the Paris Prefecture of Police, played in the Dreyfus case, to the astonishment of all, by declaring that the incriminating bordereau was in the handwriting of Captain Dreyfus, whereas it was afterwards shown that Esterhazy had manufactured it. Bertillon evolved a most complicated system, by which he sought to show the Court how he could form a conclusion concerning the character of Captain Dreyfus's writing from that of Matthieu Dreyfus, the accused's brother. None of the daily papers attempted to follow his deductions, and experts could only venture suppositions. He seems, however, to have studied Francis Galton's method. Galton photographed ten members of the same family—father, mother, child, &c.—and, by superposition of these under-exposed images, obtained an unsharp picture, which he declared was the family type. Perhaps M. Alphonse Bertillon obtained certain common expressions from letters of various members of the Dreyfus family, and photographed them one over the other, and thought he could thus establish the characteristic writing of the Dreyfus family. Principally on the ground of his opinion Captain Dreyfus obtained a free passage to the Devil's Island, such was the respect in which the dictum of the chief of the anthropometrical service was held.

It will be understood from this how important and responsible are the duties confided to an institution which has to interpret graphically the ordinary descriptive conclusions of medical jurisprudence. But it will also be acknowledged how conclusive a photograph must be to a Judge who has not seen the circumstances of a crime, when it registers the first, undisturbed impression of a deed *sine ira et studio*, and without possibility of prejudice or error on the part of experts.

FRANZ RITTER VON REISINGER.

#### SOME NEW EXPERIMENTS WITH LIPPMANN'S PROCESS.

DR. R. NEUBAUSS reports, in the current number of the *Photographische Rundschau*, on the experiments which he has made this summer on the above subject, and excuses himself for the reason that there are many questions raised which are not only of special interest for this process but also of general interest, and he points out that, if a Lippmann photograph be left for any time in the fixing bath, it completely disappears, as the silver is dissolved by the hypo, whilst it is well known that an ordinary negative may be left for a whole day without ill results; further, it is absolutely necessary to develop a Lippmann photograph at once, or the image will be considerably worse. Further, he asks the pertinent question, Why is it, if one of these photographs be soaked in water before development, the latent image is weakened?

Also, by sensitising the finest-grained plates with dyes, different experiences are met with, for the plates sensitised by bathing in solutions of dyes differ considerably as regards colour sensitiveness from those for which the emulsion was coloured, and it is unfortunate that all orthochromatising experiments are carried out by baths.

His recent experiments have been in the direction of utilising albumen plates for the reproduction of compound colours. He had already pointed out that careful reduction of the finished pictures with very dilute hypo and ferridcyanide reducer was an advantage, but that the process was very uncertain.

Assuming that the superficial gold glaze which appeared on these albumen results was due to contact with the mercury, he attempted to avoid this by protecting the film, and for this purpose the sensitised plate was coated with pure albumen and then strongly whirled. The results were, however, absolutely negative, as was also the case with a two to three per cent. solution of gelatine was used, though then Newton's rings were seen, the colour of which was dependent on the thickness of the gelatine coating.

Harking back to some of his earlier experiments with a mixture of albumen and gelatine, he tried the saturation of the prepared albumen plate with gelatine. The sensitised albumen plate, after treating with the dye, was laid for ten minutes in a two per cent. solution of gelatine, heated to 50° C. and then vigorously whirled; but even the thin gelatine skin then left on the plate was found to be prejudicial, so the plate was rinsed with hot water and then whirled. The result was striking; a plate thus treated and exposed in the spectrograph showed that, as regards the brilliancy of the colour, it had the character of a gelatine plate, and that with compound colours they were correctly reproduced just as though a gelatine plate had been used.

Whilst the plate is left in the hot gelatine solution it should be brushed with a soft brush in order to remove air bubbles.

The plates treated in this way showed a somewhat lower sensitiveness to red, and this was obviously caused by some of the cyanine in the albumen film being destroyed by the gelatine. In order to avoid this, enough alcoholic cyanine solution (1:500) should be added to the gelatine solution to give it a light blue colour.

In order to decide whether it was only the hot bath or whether the gelatine was essential, the plate was treated with hot water only, with the result that the colours were as bad as with the albumen plate not treated, thus proving the necessity of the gelatine. It was noted here that an albumen plate when sensitised could be left for ten minutes in boiling water without causing the albumen to coagulate or it to lose its developable qualities. A plain albumen plate thus treated was coagulated immediately.

Further experiments enabled a much simpler process to be discovered, whereby the four processes were reduced to two. Thus, after the plate had been sensitised in the silver bath and washed for fifteen minutes, it should be placed for five minutes in the following solution, heated to 50° C. :—

Gelatine solution (2 per cent.) .....	400 c. c.
Cyanine solution (1:500) .....	10 "
Erythrosine solution (1:500) .....	10 "

Then rinse with hot water and dry. The dyes will keep for a long time in the hot gelatine solution without precipitating.

Arising from past experiences, some experiments were made to try and trace the cause of the superficial golden glaze on albumen plates when taking compound colours. Compound colours can also produce this golden glaze on gelatine emulsion plates if the plate is over-sensitised for yellow and green, which frequently happens when sensitising with erythrosine for yellow and yellowish-green, and they have not the necessary sensitiveness for blue-green. With albumen plates the over-

sensitising for colours can be demonstrated most excellently. If the silver albumen plate is bathed only in a cyanine bath, the whole of the surface with compound colours appears covered with a reddish metallic glaze, and the red which is contained in all the compound colours alone appears. Exactly the same occurs with respect to yellowish-green when only sensitised with erythrosine.

We possess now, however, as will be seen later when we come to speak of gelatine plates, an excellent sensitiser for blue and green. If a gelatine plate is sensitised with cyanine, erythrosine, and glycin red, absolutely closed bands are obtained in the spectrum, and the metallic glaze is avoided, which is the proof of the over-sensitising with erythrosine. Experiments proved that glycin red was not so useful for albumen plates as to warrant its use.

Professor Wiener has shown (Wiedemann's *Annalen*, 1899, p. 488), both by calculation and experimentally, that the surface reflection in Lippmann's photographs considerably alters the colours, and that it is necessary to get rid of this by cementing on a cover glass.

Dr. Neuhaus found that some kinds of albumen clear very much quicker than others, some taking a few days and others several months. Cleared albumen, which had been kept two and a half years, was absolutely unchanged. When cleared albumen is exposed for a long time to sunlight, it darkens considerably, but this darkened albumen presents no advantage for this work. As several kinds of albumen show a great tendency to blister and slip off the glass, trial was made to make the albumen adhere better by treating it with formalin. With a one per cent. solution the albumen dissolved instantly, with a five per cent. solution it began to dissolve at the edges, with undiluted formalin the film became soft but did not dissolve, but, when sensitised after, this plate was absolutely insensitive to light.

If an albumen plate be laid in the agfa intensifier, it behaves rather curiously; in a few minutes the silver deposit becomes denser, and in some cases the colours are better. By continued action the plate bleaches and a white-surface fog forms and the colours disappear, but by treatment with amidol the fog disappears, the colours reappear, but are defective. When soaked for twelve hours in this intensifier, the plate is completely bleached, and by subsequent treatment with amidol a silver glaze appears as though the whole of the surface were silvered, but every trace of colour disappears.

(To be continued.)

#### FOREIGN NEWS AND NOTES.

**Coppering a Negative.**—The following process, which is described by Graf Vittorio Turati, of Milan, in Liesegang's *Photographisches Almanach*, might be useful for the preparation of small ornaments by means of photography. The negative or positive should be prepared by means of the wet-collodion process, and fixed and washed as usual, only preferably on plate glass. The negative should be placed in a clean dish, and covered with the ordinary cupric bromide intensifying solution, and then blackened with silver nitrate, and this should be repeated two or three times, and after washing the negative may be dried by heat or spontaneously. It should now be placed in an accurately levelled dish, and covered to the depth of about one millimetre with a saturated solution of cupric sulphate, and allowed to remain for about five minutes. Then should be added about half the quantity of fresh cupric sulphate solution which has been acidulated with sulphuric acid, and the dish well rocked. Fine iron filings should now be carefully and evenly sifted over the whole of the negative, when the negative image will be seen to gradually cover itself with a fine deposit of red copper, and it is then only necessary to rinse it under a tap and allow it to dry.

**Increasing Lamp Light.**—M. G. de la Furetière states that the addition of one part of amyl acetate to every four parts of paraffine not only considerably augments the brilliancy of the ordinary oil lantern for projection, but prevents the disagreeable smell of the paraffine. Whilst this may be true, it is as well to point out that the Hefner-Alteneck amyl-acetate normal lamp has to have the whole of its working parts made of solid silver, otherwise the acetate attacks them if made of brass, and it is therefore probable it might attack the body of the oil receptacle, its screws and burners.

**Diffraction of X Rays.**—Dr. C. H. Wind and Professor Haga have succeeded in producing diffraction fringes with X rays, and from measurements the wave-lengths run from 0.0000002 to

0.0000001 mm., and their conclusions are that the X rays are of the same nature as light waves, that they have a wave-length from 2500 to 50,000 times smaller than the middle of the spectrum green.

**Some New X Rays.**—A contributor to the *Revue Suisse de Photographie* affirms that he has been able to prove the existence of natural X rays, and he thus describes how he did it: In a courtyard of a house partly illuminated by sunlight he placed a sitter, so that he was just on the limit of the sunshine, and so that only his back was illuminated by the sun. On making an instantaneous exposure, the operator working in the shade and subsequently developing the plate, the sitter's head was found to be transparent, and a door six yards behind it was distinctly seen through it. The bones of the legs were distinctly seen also. The same results were obtained when working in a room lit in the same way. The editors of the said journal append as a footnote, "Cette publication est faite sous toutes réserves," and we are not surprised either.

**The Melano-chroscope.**—Under this somewhat clumsy and long-winded name, the firm of Lesueur are placing upon the market an instrument devised by Louis Ducos du Hauron for obtaining and viewing three-colour transparencies, and it is stated to be rather smaller than a 9×12 cm. hand camera, and to consist of six parts besides the camera or box as follows: A board containing three apertures, which limit the amount of subject included; a frame carrying three coloured screens, which is used not only for taking the three negatives on one plate, but also for viewing the transparencies; a dark slide and a frame, which has three grooves in it—the first is for the ground glass for focussing on and for the reception of the dark slide, and the other two grooves are for placing grey glasses in, in order to equalise the illumination of the transparencies; for taking the negative, a mirror is inserted in the camera, which gives the three images, and a perforated yellow screen or stop is used, and supplementary lenses are used for taking near objects. An eyepiece is also provided. Its use is said to be extremely simple and the results superb.

#### THE MAKING OF PHOTOGRAPHY.

[An Address delivered in Convention Hall, National Export Exposition, Monday, October 2, on the Occasion of the Celebration of the Seventy-fifth Anniversary of the Franklin Institute, Philadelphia.]

STANDING at the close of three-quarters of a century, marked by intense scientific activity attended by amazing progress along all lines, the most superficial consideration of photography and its applications exhibits it as one of the most important factors in the life of to-day evolved from that activity. Using the term in its most comprehensive conventional sense, it touches at numberless points all sciences, all professions, all trades and industries. It would be a hopeless task to compress into the limited time, very properly assigned to this the most recent branch of this section on this occasion, the most imperfect statement of the achievements of photography, to say nothing of indulgence in speculations as to its further possibilities. But the occasion does not seem to require it. It belongs to the Franklin Institute, and at this, its seventy-fifth anniversary, it seems appropriate to consider photography and its history in its relations to the Institute, for photography and the Franklin Institute were young together. They have grown up together. It has had a share in the making of modern photography. When the Franklin Institute was founded, the word photography had not been coined, or at least had not struck the ear of the lexicographer. It may have been one of many words used according to the fancy of the individual investigator to connect the accumulating facts of an inchoate branch of science, but it was not the first, and, when it did put in an appearance, it was not free from adverse criticism. There was a time when heliography may have been preferable, but with the extended industrial use of the electric light, magnesium light, and even gas light, to say nothing of the Röntgen rays, it would be much more of a misnomer to-day than photography, which word must be regarded as holding its place to-day as the survival of the fittest. It is an interesting coincidence, too, that the year that witnessed the founding of the Franklin Institute is perhaps the most important in the history of photography. It was not, it is true, the year in which any important discovery was made or announced. It was simply the initial year of those experiments that culminated in the discovery that constitutes the birth of modern photography. It was in that year that Daguerre first turned his attention to photographic investigations. For, after all has been allowed that is to be credited to, or even claimed for, others, he still remains the central figure in photographic history. Photographic events date backward and forward from him. Without his discovery, all photographic that preceded him would have been embalmed in the history of science, overlooked, and perhaps entirely lost, until revived by the touch of some such

great discovery as his. His success at once caused all records to be ransacked to be assured that he had indeed made so unique and marvellous a discovery. As usual in such cases, some things were found that at first sight seemed to reduce his claims, but which, when fully considered, do not affect them in the least. In 1824, then, he entered upon the fourteen years of solitary, discouraging, almost hopeless, but unintermitted experiments that finally resulted in the discovery to which his name has adhered. Accustomed as we have become to the almost daily announcement of similar great unexpected and unheralded discoveries, we can hardly realise the sensation it created, nor the struggle between the great desire to believe it true and the incredulity of that day, so much greater than that of our own. This was even heightened about time that by the then recent "Moon hoax," to which the announcement of Daguerre's discovery was compared, even by scientific men. In his classical history of chemistry, Kopp, who, doubtless, wrote from personal acquaintance with individuals present in Paris at the time, in seeking for a parallel to the excitement occasioned by Davy's great discovery of the metals of the alkalis, in the early part of the century, says of it, "something like that occasioned by Daguerre's discovery in our time." From that date (1839) we pass rapidly backward into the hazy prehistoric period that belongs to every branch of science, from which many interesting items have been recovered by the curiosity aroused by the practical success of his process. From that date forward we have only to note an immediate, rapid, steady development. There is no disposition by this statement to unduly magnify the merits of Daguerre, much less to minify the claims of others, but simply to accentuate the epoch-making character of his discovery. So much has been written with a bias, in many cases inspired by national partiality, and is being so frequently repeated, that the salient and indisputable facts are often overlooked. It may not, therefore, be out of place here to bring together rapidly facts generally received in such connexion and sequence as to exhibit the origin and making of modern photography.

#### PHOTOGRAPHIC RESEARCH SEVENTY YEARS AGO.

What, then, was the condition of photographic research in 1824? Overlooking all alchemistic and other accounts, however curious and interesting, but without effect upon the history of photography, we find, in 1777, the illustrious Swedish chemist, Scheele, engaged in investigating scientifically, carefully, we might almost say exhaustively, the interesting fact, long known, that silver chloride darkens under the influence of light. He allowed sunlight that had passed through a prism to fall upon silver chloride spread upon paper on the floor of the darkened room, and demonstrated that the violet ray was most effective in producing the change. He further established the fact that chlorine was liberated in the operation. But this, the usual, statement of these facts, and a correct one from the point of view of to-day, conveys a very wrong impression of Scheele's purpose, and of his interpretation of his results. The object of his investigation was not the action of light on silver chloride, but the action of silver chloride, or horn silver, as it was then called, on light, and he did not state his results in the way given. The scientific world of that day was dominated by the curious, almost fanciful, phlogiston theory of combustion. That hypothetical something, or nothing, was always present in their thoughts whilst investigating. Scheele was trying to demonstrate that phlogiston was present in sunlight, and he explained his results by saying that silver calx removed the phlogiston most rapidly from the violet ray. The change in the silver chloride he explained as loss of dephlogisticated spirit of salt. Disentangled, then, from the theories of his day, Scheele made two important discoveries which we recognise to-day as photographic. Many eminent investigators repeated his experiments. In 1798 Rumford, as the result of elaborate experiments, contended that the change was due to heat, and not to light. In 1801 Ritter, incited, doubtless, by the detection of heating effect, by Sir W. Herschel, the year before, in the space beyond the red of the spectrum, announced the discovery of photographic effect in the invisible region beyond the violet. He also demonstrated an opposition of the effect of the red and violet rays, and explained it by an oxidising action of the former, and a reducing action of the latter. In 1802 Wollaston arrived at substantially the same results; but, in investigating Ritter's explanation of the opposition of the red and violet rays, from which he dissented, he employed a photographic substance of a new class, namely, gum guaiacum, and considered its change of colour under the influence of light. In 1804 Young employed a silver salt successfully to investigate Newton's rings projected by a solar microscope. So Vogel, Seebeck, Senbier, Davy, Berard, in fact, almost every scientific man of prominence of that period, pursued similar lines of investigation. The motive of most of these was strictly scientific, such as the determination whether the solar beam contained three essentially different agents, of which the actinic was but one, the photogenic production of the colours of the spectrum, the exploration of the invisible regions of the spectrum, and the like. In the apparent chaos of carefully observed facts there are many that advanced photography of to-day imparts new interest to and that might well repay reinvestigation. There was but one notable attempt at practical application of facts. In 1802 Thomas Wedgwood, son of the porcelain manufacturer, in connexion with Davy, published a method of copying pictures painted on glass,

fibres of leaves, wings of insects, and so forth, by pressing them in contact with paper coated with nitrate or chloride of silver, and exposing to sunlight; but, failing in all their efforts to prevent the continued darkening of the pictures obtained in this way by the action of light, they were obliged to preserve them in the dark, and could only examine them by candle light.

#### NIÉPCE AND DAGUERRE.

During the decade preceding the founding of the Institute there was almost a complete lull in scientific activity along these lines. During this time, however, there was one man, Nicéphore Niépce, who had been working on from 1814, with great tenacity of purpose, trying to fix the images of the camera. He had sufficient suggestions of success to keep him at work. He did not approach the subject from the scientific side, nor from purely scientific impulses, but with a desire for immediate practical results. He had become interested in the recently discovered process of lithography. The difficulty of procuring suitable stone suggested the use of metallic plates, and it occurred to him to substitute light for the hand in drawing the pictures. After experimenting with various substances, among them silver chloride, he discovered that bitumen of Judea was rendered insoluble in certain solvents by the action of light. He coated metallic plates with a thin varnish of it, exposed them when dry to the sunlight under engravings previously varnished to render them more transparent, and then dissolved out the unchanged bitumen of the parts protected from the light. After a measure of success in thus copying engravings, he experimented with the pictures of the camera on similar plates, and there seems to be no question that about 1827 he had obtained pictures by this process, however imperfect. He named the process "heliography."

In 1824 Daguerre, entirely ignorant of Niépce or his work, entered upon a similar pursuit, upon parallel lines, inspired by a similar desire for immediate practical results. He was a scene-painter in Paris, and an artist of no mean character, and of great popularity in that city. The diorama, invented by him, was the sensation of the day. Crowds were entertained by its surprising effects. He was aided by the camera in preparing his scenes. The wish to fix its fleeting pictures might occur to any one, but it took complete possession of him, although the pursuit was more unpromising than that of the alchemists. He worked alone and in secrecy, with but little encouragement. His methods were empirical rather than scientific. About 1826 he learned of another worker in the same field. He immediately wrote to him, Niépce, distrustful of the unknown writer, threw the letter in the fire. A letter a year later met with a better reception. The correspondence continued, at first with almost suspicious reserve. Niépce visited Paris, met Daguerre, was greatly impressed with his diorama. Both seemed to enjoy an exchange of experience that belonged to them alone. Niépce wrote his son that Daguerre persisted in regarding his (Niépce's) process as better than his own, but that one thing was certain, they were entirely different. A partnership, styled Niépce-Daguerre, was formed, with equal interest. The article of agreement, dated December 14, 1829, was signed by Niépce as "Landowner, at Chalons-sur-Saone," and by Daguerre as "Artist-painter. Member of the Legion of Honour, Manager of the diorama." Under the terms of the partnership, Niépce contributed his process of heliography, and his experiments, which Daguerre agreed to assist in improving, and also contributed his improved camera, which was regarded as of great value, as it most likely was. Daguerre improved the process, but was diverted altogether from it by the accidental discovery of the sensitiveness of silver iodide to light. In the bitumen pictures the blacks of the original were represented by bright polished metal, from which the unchanged bitumen had been removed, and the whites by the changed bitumen. To convert these negative pictures into positives, Niépce experimented with a variety of substances, among them vapour of iodine, to darken the exposed metal, and then dissolved off the bitumen from the whole plate. It is said that Daguerre observed that the shadow of a spoon that happened to be lying on a polished silver plate that had been exposed to the vapour of iodine was permanently impressed upon it. Slight as every one knows this direct effect of light on iodide of silver to be, Daguerre seemed to see in it new possibilities for camera pictures. Niépce, however, after experimenting with it at Daguerre's suggestion, expressed regret that he had lost so much time in following his recommendation. He repeated that he did not see that they could hope to secure any advantage from this process, and suggested other substances as better. Niépce died in 1833. Success seemed as remote as at the formation of the partnership. The partnership was renewed with the son, Isidore Niépce. Daguerre now entered with even greater enthusiasm and undivided effort into the pursuit. He neglected the diorama, and lived in his laboratory, to which no one had access, not even Isidore Niépce. He became so much wrought up by his unsuccessful experiments that his wife, according to Dumas, consulted physicians in regard to his sanity. Finally there came to his assistance an accident which conducted to a fundamental discovery, as fundamental to-day as it was then. The mode of the discovery has not only a species of romantic interest of its own, but, as I recollect it, given by Professor Liebig in one of his lectures, as one of the finest specimens of the inductive method, coming thus from one thoroughly familiar with the Paris of that day, it has an added air of authenticity that may excuse the narration of it in this con-

nexion. Daguerre's method of experimenting was to expose polished silver plates to the vapour of iodine until coated with a layer of iodide, then to subject them to the image in the camera. These plates, always without the hoped-for result, or at most the very feeble direct effect, were repolished, re-iodised, re-exposed in the camera, with the same disheartening results. On one occasion, upon removal of such an exposed plate from a closet in which it had been stowed, to repolish it for a new experiment, to his great surprise he found upon it the view to which it had been exposed in the camera, not an uncertain, feeble picture, such as he had been accustomed to, but a strong, clear, unmistakable one. He exposed another plate in the camera without visible effect, stowed it in the closet, again to find the invisible picture put in an appearance. He had no way of explaining the result. All his years of investigation furnished him no clue to the influence at work. He set about systematically to discover it. He could only conclude that it must be something in the closet. He placed plate after plate, after exposure in the camera, in the closet, each time first removing something from the closet. Each time the invisible became visible. At last nothing remained but some mercury spilled on the floor of the closet. Thus by this method of elimination the magician was detected. It was a short step to subject plates that had been exposed in the camera to vapour of mercury, and the Daguerreotype process was complete.

#### FOX TALBOT.

This early period of photography cannot be passed over without mention of the name of Henry Fox Talbot, of England. He was a man of many-sided scientific character, and an independent investigator in the photographic field prior to Daguerre's discovery, and therefore not inspired by it to investigation. In 1839, January 31, he read a paper before the Royal Society, entitled "Some Account of the Art of Photogenic Drawing," &c., embodying a practical process on paper based on the abandoned process of Wedgwood and Davy, which he improved and also completed by fixing the pictures, although imperfectly, in a solution of common salt or potassium iodide. The substitution of sodium hyposulphite, first suggested by Sir John Herschel, for the iodide soon followed. He further suggested indefinite photographic multiplication of the paper originals, by taking impressions from them on similarly prepared paper, and, upon the publication of Daguerre's discovery of a latent effect of light, was quick to apply it to the preparation of a paper sensitive enough for camera impressions, and, by rendering these transparent, greatly facilitated indefinite photographic multiplication of the original negatives as positive pictures, although the terms negative and positive, in this connexion, were first used by Herschel. His Calotype process was patented by him in 1841. Although there is nothing in it that would call for the association of his name with those of Daguerre and Niépce, yet, as an independent investigator, scientifically trained, he deserves prominent mention, as one whose applications of known facts at once greatly stimulated the practice of photography and its consequent rapid improvement. In addition to the introduction of photographic multiplication by the use of a translucent support for the sensitive compound of silver, the replacement by him of the formation of such a compound by the direct combination of the halogen with the silver, as in Daguerre's process, by the reaction between silver nitrate and a metallic haloid, was typical of more modern photography.

#### DR. J. W. DRAPER.

It is interesting at this point to note the reception of the discovery in America. There was at least one man thoroughly ready to appreciate the scientific features of the process and to apply it. The numerous papers contributed to the *Journal of the Franklin Institute* by Dr. John W. Draper, several years before Daguerre's discovery, detailing investigations, are classical, and surprise us even to-day by their minute accuracy and anticipation of solutions of questions long subsequent. But he escaped making Daguerre's discovery. He succeeded, however, in doing what Daguerre had not yet succeeded in accomplishing. He took the first portrait by Daguerre's process, although, as we shall note, this claim is disputed in favour of a Philadelphian. He took the first photograph of the moon. He applied the process in a variety of ways in scientific investigation. But nowhere did the announcement lead to practical application as quickly as in Philadelphia. The old American Philosophical Society and the then young Franklin Institute had members alert for anything that was new in science. Joseph Sexton took the first photographic view in America, out of a window of the Mint with very crude apparatus in October 1839. Robert Cornelius, a lamp-maker, took a portrait in the latter part of 1839, some claim before that made by Draper. The Franklin Institute, in its Exhibition in 1840, displayed some of the first results. The *Ledger*, in its account, October 12, states: "Throughout the room are various specimens of the Daguerreotype. They consist mostly of miniatures." This shows great enterprise for a day of sailing vessels, when it is remembered that Daguerre's process had only been made public in Paris in August 1839. But the part that Philadelphia had has been so fully treated in a lecture before the Franklin Institute, several years ago, by Mr. Julius F. Sachse,\* and published in its *Journal*, that I can do no better than to refer to it.

\* Sachse, "Philadelphia's Share in the Development of Photography," *Journ. Frank. Inst.*, 135, 271.

But one fact of permanent effect, and of exceeding interest in this connexion, is the strong body of amateurs in the art which sprang up in Philadelphia, and which has always characterised it; strong not only in numbers, but in scientific character and motive.

I think I am not mistaken when I assert that the first independent photographic society in America was the Philadelphia Photographic Society, as the American Philosophical Society was the earliest scientific society. It was organized in the heroic days of photography, when the practice of photography meant a great deal, when press-the-button and snap-shot work were unknown. Members of the Philosophical Society and of the Institute were active in founding it, and making its creditable record. Dr. Coleman Sellers, President of the Institute, was a prolific writer on photographic subjects, always instructive and practical. Joseph M. Wilson, who is doing so much to give Philadelphia pure water, also a former President, has been an enthusiastic amateur from his boyhood. There are so many others, who have not filled that high position, active in advancing photography, that I must refrain from mentioning any, except Matthew Carey Lea, so well known as one of the most indefatigable, painstaking scientific investigators, whose contributions to this subject, largely along lines all his own, are not only of present practical value, but full of promise to investigators, which the future will doubtless realise. His apparatus, bequeathed to the Franklin Institute, will form a fine nucleus for the encouragement of photographic investigation. When Professor Henry Morton, then Secretary of the Institute, organized the highly successful expedition to photograph the total eclipse of 1869, under the auspices of the National Government, he was able to draw largely from the membership of the Institute for his efficient corps of observers.

#### RUSSELL; MADDOX; SAYCE AND BOLTON.

But to return to the development of photography. One of the most tantalising defects of the process, as published by Daguerre, was its slowness. It suggested portraiture, but just came short of desired success. In 1840 the requisite increase of sensitiveness was obtained by the use of bromine in connexion with iodine, and the trio of silver haloids in use to-day was completed. This use of bromine as an accelerator, as it was called, was published by Goddard, of London, in 1840. The honour of its introduction is also claimed for Philadelphia, where Dr. Paul Beck Goddard—a singular coincidence of names—employed it as early as 1839, but, as he kept the fact a secret until 1842, whilst we are privileged to believe that he first used it, we cannot claim the honour for him as against prior publication. The process, it seems, was employed at once commercially here with greater success than in France. Daguerreotype portraits were taken at five dollars each. The Calotype negatives of Talbot, with the objectionable grain of the paper, suggested better things. Glass had been used by Herschel in some experiments with silver chloride, and negatives on glass, with albumen as the vehicle of the silver iodide, which afforded excellent paper prints, were first produced by Niépce de St. Victor, nephew of Niépce, in 1847. The Daguerreotype began to recede in importance, and amateur practice of photography was stimulated. In 1850 the greatest advance since the time of Daguerre was made by the introduction of collodion, a solution of gun-cotton, then recently discovered, as a vehicle of the sensitive silver iodide. Glass and collodion seemed to possess all desired properties for photographic purposes. Nothing better seemed possible. The Daguerreotype disappeared entirely. A collodion positive process on blackened metal, an American invention, in a measure took its place, and survives to this day as the tintype. The collodion process, however, was soon found uncomfortably cumbersome by the growing number of amateurs, requiring as it did the completion of the whole process whilst the plate was still wet, necessitating the impedimenta of tents, bulky solutions, fragile vessels, &c., for outdoor work. The dispute continued for a decade between *humidus* and *siccus*, as to the relative merits of the wet process and various dry-plate processes devised from time to time. At last, in 1862, the tannin dry-plate process of Major Russell seemed to be satisfactory in results, but slow in exposure, and time-consuming in the preparation of the plates. In the wet-collodion process the metallic haloid was added to the collodion, and the plate coated with it immersed in a solution of silver nitrate, where the reaction took place, producing the silver haloid. The question naturally arose, Why not eliminate one of the most troublesome factors of the process by adding the silver salt to the collodion? In 1864, Bolton and Sayce overcame the intrinsic difficulties, and produced an emulsion of silver haloids with collodion suitable for the purpose. The process became commercially available, and bade fair to revolutionise photographic practice; but, in 1871, Dr. R. L. Maddox succeeded in producing workable plates with an emulsion of gelatine and silver bromide. The process was at once taken up, and brought by rapid stages by different workers to a high degree of perfection. Dry plates of wonderful rapidity, of great certainty and ease of manipulation, and of practically indefinite keeping qualities, were soon placed upon the market. Again a Philadelphian, and member of the Institute, John Carbutt, manufacturer, was among the very first to recognise the commercial possibilities of the new process and erect a plant to meet the demand sure to spring up. The professional adopted them slowly. The amateur recognised in them the long-desired dry plate. Photographic societies in the United States, mainly of amateurs, increased, in the decade from 1883 to 1893, from 9 to 120, or more than

twelfold. Manufacture of cheap, but good, dry-plate outfits, which dispensed with the more expensive wet-plate holder, assumed very important proportions. Dry plates, and improved developers and appliances for dry plates, began to predominate in the advertising columns of the journals, and detective cameras, as hand cameras were generally called at first, were largely advertised in periodicals in which photographic advertisements had not appeared before. But the amateur complained now of the weight of glass to be carried. A return to paper for negative purposes was made, expensive apparatus devised to coat it, and with excellent results. The critical amateur withheld his patronage. At last a substratum was produced in celluloid—singular to say, with gun-cotton as a chief ingredient—having the essential photographic properties of glass, but tough as well as light; but still the enthusiastic, patient amateur, with almost infinite capacity for trouble, but always seeking lines of least resistance, striving to avoid the unnecessary in his work, and keenly sensitive to discomfiture, complained that he had to retire to the dark room or changing bag before his day's work was half done. Again his complaint was met by the daylight loading roll of sensitive film, which will permit a year's snap-shooting without entering the dark room.

VOGEL; IVES; HERSCHEL; WILLIS, &c.

The discovery by Professor Vogel, in 1874, of the possibility of rendering plates sensitive to colours generally regarded as non-actinic, by treating them with suitable dyes, constituted the most distinct advance in photography since the days of Daguerre, widening its range of applications. Fredk. E. Ives, of the Institute, published the first perfected orthochromatic process. Orthochromatic plates soon appeared in the lists of up-to-date manufacturers.

The processes for multiplication by action of light have sympathised with the general progress of the negative practice, but have not kept pace with it. The direct printing-out processes in use from the earliest albumen-coated silver-chloride paper down through the papers of various names, coated with gelatine or collodion as vehicles, with their dependence on daylight for printing and their subsequent operations, are ante-Daguerrean in principle, and almost anachronisms in this day. The developing papers, with their independence of daylight, and in the "Velox" type permitting developing by comfortable gaslight, and, with suitable apparatus for exposure, yielding 5000 prints per day, seem more nearly up to date.

But all processes with silver are viewed with distrust in regard to permanency. Two processes at least are regarded with more favour in this respect, and are recommended by the National Photographic Records Association of Great Britain for its photographs. The carbon or pigment process, which carries back in principle to the time of Niépce, based upon the discovery of Mungo Ponton in 1839, of the loss on exposure to light of solubility or stickiness by gelatine and other organic substances, mixed with alkaline bichromates. The other, the platinum process dependent upon the reduction of a ferric to a ferrous salt by light, one of the many discoveries of Sir John Herschel, and the reducing action of the latter on a platinum salt also present in the paper. The process, originally patented by Mr. Willis, now free, is simple in manipulation, and yields artistic effects as well as permanent prints. The blue print process, humblest of all, but yielding a larger acreage than all others, also originating with Sir John Herschel, is based on the reduction of a ferric salt, and, as practised to-day, also in some degree upon the reduction of a ferricyanide.

But a thought ever present with investigators has been the multiplication of pictures by other than purely photographic methods. Niépce started with the motive of etching plates by means of light for printing. Attempts were early made to convert the Daguerreotype into a printing surface. In recent years processes based on the properties of gelatine mixed with alkaline dichromates have been commercially highly successful, as photo-lithography, the heliotype, Woodburytype, swelled gelatine and wash-out gelatine processes, &c., some capable of rendering all the tones, others restricted to black and white, but none of them meeting the growing demand for typographic blocks capable of rendering the shades of the original. At an early day it was found that, by breaking up the shades by a grain imparted to the printing surface in different ways, half-tones could be simulated, and the line screen was one of the methods for so doing. But in none of these methods was there an attempt at what might be termed a discriminating grain, a precise rendering of the shades, as an engraver would do, by lines and dots of varying sizes and separation. In 1891, Frederic E. Ives, of our Institute, patented and conducted commercially a process that might be characterised as ideal in this respect. By it all the tones of photographs and wash drawings could be faithfully rendered by typographic blocks. The testimony most conclusive on this point, perhaps, is the criticism of the art critic of one of the leading dailies of New York of engravings in a work which called for art of high character. To quote his words in regard to some pictures selected by him as the "finest in the book," he says: "Without detracting from the artist's meed of praise, it may be added that the most remarkable thing about these illustrations is the extraordinary skill displayed by the engraver," and he speaks of the "marvellous delicacy of precision and touch," "power of taking up the theme submitted by the artist," &c., and yet they were soulless photo-engravings by Mr. Ives's purely mechanical process. The blunder of the critic does not reflect on his professional

character, but only on his ignorance of the resources of photography. This process has been largely replaced in recent years, for the requirements of the general trade, by the more facile line screen half-tone process, greatly improved by the variation and proper manipulation of the screen and stops employed, and by attention to the optical conditions involved.

#### COLOUR PHOTOGRAPHY.

Colour photography, the dream of every one interested in photography, has seemed to many beset with apparently incompatible conditions, and the unattainable limit of photographic progress. It has none the less, from the earliest period, engaged the attention of the ablest investigators.

A measure of success has been announced from time to time, by Seebeck in 1810, and subsequently by Sir John Herschel, Becquerel, Niépce de St. Victor, Poitevin, Simpson, and others. In all cases a difficulty in fixing the pictures has prevented a much-desired general inspection. The following extract from a letter of Sir John Herschel, in 1865, is one of the most favourable accounts: "I received a complete coloured spectrum picture from Becquerel several years ago, which is still as fresh in colour as when received. The whole spectrum from end to end, is not brilliant, is still distinct. I seldom examine it, and only by lamp light." The more recent process of Lippmann, founded on interference of light, is of great scientific interest, but, if it has a commercial future, has not yet passed its experimental stage. Other less direct processes seem more practicable. The so-called Joly or McDonough process, dependent upon a taking screen of lines in intimate contact, coloured in series red, green, and blue, placed before the plate in taking the negative, and used in viewing the result, is also short of commercial success. The heliochromic process of Frederick E. Ives, in conjunction with the kromskop, comes nearer the complete realisation of reproduction of natural colours, and is commercially available. It requires three negatives simultaneously taken, representative of the Young-Helmholtz-Maxwell colour sensations, and three positives simultaneously presented to the eyes in the kromskop, by light through glass or screens (red, green, and blue-violet) suitably coloured for each. The camera for taking the negatives and the instrument for viewing the positives are ingenious and practicable. Until some process, based upon some new material, or new principle, is discovered, this process is likely to hold its present place. Possibly the silver photo-haloids investigated by M. Carey Lea may yet lead to the perfect colour process.

#### X-RAY WORK.

The scientific world, hardly recovered from the shock of surprise at Röntgen's discovery, and undecided whether it is dealing with rays or emanations, led by it, seems entering a new and broader field of investigation, almost uncanny in some of its aspects. The terms Becquerel rays, Russell rays, metallic radiations, vaporography, and the like are full of import. As stated by Dr. Crookes, "Some bodies without special stimulation are capable of giving out rays closely allied, if not identical, with those of Röntgen, and it would almost seem, from the important researches of Dr. Russell, that this ray-emitting power may be a general property of matter, for he has shown that nearly every substance is capable of affecting the photographic plate if exposed in darkness for a sufficient time." The list of active substances is a long one, to which a recent investigator has added the human body. The rays pass through many opaque substances, and are checked by others. They excite fluorescence. Already they have led to the discovery of a new metal by Madame Curie, and named polonium, possessing 400 times the energy of uranium, which has hitherto held the highest place. It was announced in the morning paper that Professor George F. Barker has brought with him from Paris a specimen of the new metal, and we trust we may look for some demonstration of its properties at an early day. This energy seems to be without exciting cause, and without perceptible diminution. If radiant energy, may not perfumes, which have been regarded as material emanations, be of the same character, and the rose emit rays that will affect a properly sensitised plate?

#### THE LATEST APPLICATIONS.

Photography and the microscope, too, have gone hand in hand with a more intimate sympathy even than that between the camera and the telescope. Among the earliest amateurs of highest character was a large percentage of experts with the microscope. It was in the decade following the founding of the Institute that the microscope began to assume something of its present character as an instrument of delicacy and precision. In 1831 the factory of Ross was established, and, under the stimulus and co-operation of such men as Herschel, Airy, Powell, and, more especially, Lister, improvements in the optics and mechanics of the microscope were rapidly made, so that, at the discovery of photography, microscopy had an entirely modern aspect, and it recognised at once a new ally. Dr. Draper immediately took micro-Daguerreotypes. From this time the improvements in optical appliances urgently demanded by the microscopist were ably seconded by the photographer, and both combined were largely instrumental in occasioning the marked progress in practical optics, which, in turn, reacted to advance photography and microscopy. Even in the days of slow wet collodion, good work was done with the microscope, and even stereo photo-micrographs were taken

by Professor Rood. The rapid dry plate, sensitive to all or any desired colours, has nowhere contributed more to the advance of photographic practice than with the microscope. It has become to it only less the observing and recording eye than to the telescope. The intimate connection between the microscope and the camera is also well exemplified in the Institute, where the gifted Zentmayer gave the world its best model for the microscope, and the lens which bore his name long filled a place entirely its own in photography, and when the Government placed the administration of the Total Eclipse Expedition of 1869 in the hands of Professor Morton, then Secretary of the Institute, it was unnecessary to seek further for the complete solution of the then new practical optical questions involved in such an enterprise.

In chemistry, Dr. Crookes, by aid of photo-spectroscopy and ortho-chromatic plates, has added the metal monium to the list, with its characteristic lines far out in the ultra-invisible light, in the phosphorescent glow of yttria under molecular bombardment in *vacuo*. Meteorological science is enriched by photography. It is pertinent to mention the interesting contributions of W. N. Jennings, of the Institute, to the study of lightning discharges, and the work of C. Francis Jenkins in the conversion of a scientific toy into the panthascope, which has found its extension in the kinetoscope, and which earned for him the Cresson medal of the Institute. The kinetoscope, with its miles of photographic films, as exhibited first by our H. R. Heyl, has found applications unanticipated in recording the movements during a solar eclipse and of growing plants, and has gone to the front with the army in Africa. In the industries the applications of photography are of infinite variety in character and importance. It is proposed to furnish cards for the Jacquard loom, and thus make tapestries commonplace. It will furnish water marks for paper capable of 100,000 impressions. It reproduced the *Encyclopædia Britannica* at one-third the cost of type. It preserved the valuable MS. copy of *Century Dictionary*, which was practically unseizable, in miniature form against loss by fire. It may, in the future, in the same way, find a place to economise shelf room in our libraries by compressing books that are seldom or never read. Its applications are well known in the copying of inscriptions, even in dark interiors, in the preservation and duplication of valuable documents and papers, in the detection of forgeries, especially by the method of composite photography as developed by Dr. Persifer Frazer, in the furnishing of legal evidence in general, in the detection of criminals, &c. In Canada, 50,000 square miles have been plotted by means of the photo-theodolite. In the late war the camera went to the front, and has furnished invaluable records. *Apropos* to this, it is only necessary to recall Capt. Wise making exposures whilst charging up San Juan Hill. In the present African war it promises to play an important part in reconnaissance through the tele-photo apparatus that accompanies the British forces.

CHARLES F. HIMES, PH.D., LL.D.

#### A PRINT AND PLATE-WASHER.

MR. R. GREENLAND has patented a piece of apparatus for this purpose. It consists of a tank or dish for washing photographic prints, plates, films, and the like, as shown in fig. 1, containing a tray or trays, as

Fig. 1.

Fig. 2.

fig. 3. Fig. 4 shows a side elevation of fig. 3. The said trays to be made in separate compartments, as shown at v (fig. 3). Each compart-

ment having all four sides hinged, shown at b, and covered with a wire-netting. The framework of the bottom of tray, v (fig. 3), forms spindles for the sides, b1, b2, b3, and b4, to work upon. The said sides are looped round v at o. b1 goes under b2 and over b4. b2 goes over b1 and over b3. b3 goes under b2 and under b4. b4 goes under b1 and over b3. Projections are shown at w, which prevent sides falling on to prints in the compartments. The said sides of tray, b, can be opened to place prints and the like in, and closed and fastened as shown in fig. 3 at 6; by this means the water passing under and over the said prints cannot dislodge them, or allow them to come in contact with each other. The bottom of tray is covered with netting, as shown at f (fig. 3). Fig. 2 is section, A, A, of fig. 1. A tube, g, is fitted to tank; the other end of

Fig. 3.

Fig. 4.

tube can be fitted to any ordinary water tap. Water passing down the said tube, g, into a director or guide, n, (as shown in fig. 1 and fig. 2,) to break the force and send a steady current along the tank flowing over and under the print in its course. The water then passes over a partition, weir, or overfall, h, which slopes at an angle, as shown in fig. 2, from the bottom of tank towards the tap, and away from entrance of water. Holes are placed in the bottom of tank, as shown at x, under partition n, to let off the exhaust water. Any light that might enter exhaust holes, x, is prevented from coming in contact with sensitive matter in the tank by the said weir, or overfall, or partition, n, which slopes directly over the said exhaust holes, x. The tank or dish is fitted with a light-tight lid, w (fig. 2). The tank is raised upon legs, as shown at r (fig. 2).

#### TO PHOTOGRAPH THE SOLAR CORONA IN 1900.

In a late number of the *Oakland Inquirer* we find a pretty full statement of the preparations of Charles Burckhalter, Director of the Chabot Observatory, at Oakland, Cal., for the expedition which he has organized to observe the total solar eclipse of May 28, 1900. In the last number of this publication, says Mr. W. W. Payne, in *Popular Astronomy*, will be found a large plate, as frontispiece, which shows the full length and width of the track of totality, to scale, as it passes over the southern part of the United States. Mr. Burckhalter's point of observation for his party is somewhere in the State of Georgia.

The particular reason for calling attention to the work of this expedition is to speak of the novel photographic instrument that Mr. Burckhalter is expecting to use on that occasion.

Some time ago Mr. Burckhalter believed that he had devised a plan which would materially assist astronomers in photographing the solar corona in regard to regulating the exposure of the sensitive plate for exterior and interior portions of it. So far, by the ordinary methods of photographing this delicate and most beautiful phenomenon, it has been quite impossible to secure on the same plate the wonderful detail of the inner corona and also the faint exterior streamers which make up the outer corona. The reason for this photographers well understand and any one may easily realise, when it is said that the time of exposure of any object depends on its brightness. The brighter the object the shorter should be the time of exposure to get its structure in full detail. If the exposure of a bright object, like the full moon, is too long, the light portion of the surface will be covered with blotches of light, in which most of the interesting detail is lost. In the darker parts of the surface, for example the seas, more detail will appear, for the simple reason that such parts need longer exposure to bring the detail desired.

This is the main point on which Mr. Burckhalter has been working in relation to photographs of the solar corona. The corona of the sun as seen in the period of totality in an eclipse is pearly white in colour, even brilliantly so, and extends outwards from the sun in all directions to a distance of one-half of the solar diameter, and also in some directions much further, in the form of streamers that gradually become fainter until lost entirely in the dark sky at a distance of two or three diameters of the sun.

That part of the corona which lies near the sun is intensely bright, and made up of varied and delicate structure so complex, distinct, and impressively beautiful, that the astronomer longs to have some means to get and keep the charming picture always. Then, when the eye is turned to the outer corona and its streamers, the brightness diminishes so rapidly that the contrast is very marked, and the great difficulty of photographing both parts of it on the same plate at once immediately appears. The apparatus devised by Mr. Burckhalter to overcome this very troublesome condition consists of two telescopes, one known as the Pearson photographic telescope, and the other as the Pardu lens. The focal length of the Pearson lens is said to be fifteen feet. The manner of mounting the telescopes is not fully enough stated so as to give a clear idea of this part of the preparation. The aim appears to be to have the two tubes of the telescopes so related, that photographs by them both may be taken in duplicate under the same conditions if so desired. The special device for work on the corona in the brief period of totality has for its object the exposure of the sensitive plate in such a way that each part shall have the right time limit. In this way it is expected that the interior corona will not be over-exposed, nor its exterior parts under-exposed, a result which every astronomer may well hope can be secured. This carefully graduated exposure is to be effected by means of a diaphragm, revolved by clockwork before the sensitive plate, which will vary the time of exposure for different parts of it from two hundreds of a second to ten seconds of time, or for other differences of time as desired. If such an arrangement for using the varying intensities of the light of the corona can be gained successfully, very interesting results ought to be secured. The period of totality in this eclipse will be only eighty-six seconds, and the width of the black path on the earth's surface about forty miles. This very short time of totality will afford observers scant opportunity to do the many things planned for, yet astronomers have learned to work more rapidly in later years, and the improved apparatus now in use will make up to some extent for lack in length of totality.

The things to be attempted during the total solar eclipse in May 1900 are a photographic search for intra-mercurial planets, and a study of the brightness of the sky. Professor W. H. Pickering is reasonably sure that a body the size of an average asteroid, say twenty miles in diameter, within 15,000,000 of miles of the sun, would show on photographic plates he uses. It is encouraging to know that astronomers do not give up the search for these small bodies near the sun, although work during the past twenty years in this direction has not been successful. Another thing is the study of the details in the structure of the corona. The photographic work already spoken of may aid materially in this, but there is also need of careful visual work with good telescopes, in this country, Spain, and Portugal, for the sake of comparing results obtained from the same kind of work in a prearranged programme. This idea seems to be in considerable favour with those using the telescope chiefly.

One astronomer suggests the desirability of measuring the "rate at which the radiating power of the solar atmosphere is diminished with the altitude above the photosphere, and to obtain a rough quantitative comparison with photospheric radiation." Other themes are the lower red in the spectrum, the "flash spectrum" work with the photometer, and the polariscope. Though the time of the eclipse be short, it is probable that many American parties will participate in the observation, and, if the day be a favourable one, some useful results will be expected.

## ON THE USE OF MERCURIC IODIDE FOR INTENSIFICATION.

[Translated from the Bull. de la Soc. Franc. de Photographie.]

THE use of mercuric iodide as a direct intensifier of negatives was first mentioned by Edwards\*, who used mercuric iodide dissolved in sodium thiosulphate. Later, Vogel† made some slight modification in the composition of the solution given by Edwards, who afterwards confirmed Vogel's results‡.

According to these writers the intensifier is prepared by precipitating 4 grammes of bichloride of mercury, dissolved in 200 c. c. of water, by means of 10 grammes of potassium iodide dissolved in 65 c. c. of water. About 8 grammes of sodium thiosulphate is then added, dissolved in 65 c. c. of water. These proportions correspond to one molecule of mercuric iodide to two molecules of sodium thiosulphate with excess of potassium iodide.

The proportion of sodium thiosulphate in this formula must not be

\* *Photographic News*, 1879, p. 514. THE BRITISH JOURNAL OF PHOTOGRAPHY, ALMANAC, 1881, p. 57.

† *Photographische Mittheilungen*, xvi. p. 340.

‡ THE BRITISH JOURNAL OF PHOTOGRAPHY, 1879, p. 361.

increased, since, as we shall see later, the intensified image partially disappears in sodium thiosulphate, and intensification no longer takes place when an excess of this salt is present.

The intensification of negatives with mercuric iodide and sodium thiosulphate possesses not only the advantages of giving great vigour and of being capable of moderation by addition of water, but also of taking place directly in one solution, so that no second bath is required before the colour and intensity of the negative can be judged; but it has one important defect, the intensified image is not permanent, with the lapse of time it becomes yellow and decreases slightly in density.

The cause of this change has never yet been definitely stated. In order to find the means to remedy the defect, we have first endeavoured to clear up the theory involved in the intensification process.

*Hypotheses of the Reactions involved in the Use of Mercuric Iodide and Sodium Thiosulphate for Intensification.*—It may be supposed that the solution of mercuric iodide in sodic thiosulphate is due to the formation of a double salt of the formula,  $\text{HgI}_2 \cdot 2(\text{Na}_2\text{S}_2\text{O}_3)$ , which corresponds with the relative proportions of the substances entering into the composition of the reducer. On the other hand, it is conceivable that double decomposition takes place, and iodide of sodium, and thiosulphate of mercury and sodium are formed. Thus,  $\text{HgI}_2 + 2\text{Na}_2\text{S}_2\text{O}_3 = 2\text{NaI} + \text{HgNa}_2(\text{S}_2\text{O}_3)_2$ , but the ease with which iodide of mercury is recovered from the solution favours the first rather than the second hypothesis.

Let us assume, then, that the iodide of mercury exists simply dissolved in the thiosulphate. We may suppose that, by reacting with the silver image, it is reduced to mercurous iodide:—

At a second stage, this mercurous iodide would be decomposed by thiosulphate of soda, forming mercuric iodide and metallic mercury. The mercuric iodide, thus re-formed, would be again reduced to the mercurous state by the silver of the image; and so the cycle of changes would go on, the thiosulphate taking part in the reactions only as a solvent of mercuric iodide.† The equation would be as follows:—

or the whole reaction can be written thus:—

The intensification would thus be due to a mixture of mercury and iodide of silver.

This hypothesis is to some extent confirmed by the fact that the image thus obtained can be readily weakened by treatment with a solution of thiosulphate of soda, which dissolves the iodide of silver. If only a part of the silver iodide is dissolved, this reduction is only partial; but it is possible to return to the original intensity of the image by completely dissolving the iodide of silver. Only the colour of the image is then modified, having become somewhat browner.

*Rapid Alteration in the Image.*—We have found that the change taking place in the intensified negatives in several months can be produced in a few hours. Hitherto this change has been erroneously attributed to the action of light and air, but it is produced simply by leaving the negatives in water. That it is not the salts present in ordinary water which are responsible for the change was proved by the same result being obtained with distilled water. The image, which is originally a brownish-black, yellows gradually, and the change produced in this way appeared precisely the same as that produced by a long exposure to light or air; it can also take place in the dark.

*Nature of the Change.*—We have endeavoured to determine the character of the substance which is thus produced. We first imagined that the change of colour was due to the formation of mercurous iodide (by the action of mercury on silver iodide), or possibly even of mercuric iodide; but the following reactions show this supposition to have been false:—

1. The compound is not blackened by the usual reagents which convert mercurous iodide into mercury and mercuric iodide, such as sulphite of soda and potassium iodide.
2. Under the action of hyposulphite of soda the image weakens, and the yellow compound dissolves; this would not take place in the case of mercurous iodide, which blackens under thiosulphate of soda.
3. Solvents of mercurous iodide, except thiosulphate of soda, have no action on the negative.
4. It gradually bleaches in dilute nitric or hydrochloric acid.
5. Dilute ammonia has no action on it.
6. It is slowly reduced by reducers of iodide of silver, and the image blackens without any apparent increase in opacity.

It can be supposed that, under the influence of moisture and oxygen, the mercury oxidises and forms with iodide of silver a compound of a

\* Prumm, *Photographische Mittheilungen*, 1880, p. 7. Debenham, *Photographic News*, 1882.

† It is possible to imagine the action consisting in the reaction of mercurous iodide upon thiosulphate to reduce the latter to tetrathionate:—

but the facility with which mercuric iodide is obtained from the solution, and the similarity of the results when other solvents of mercuric iodide are used, lead us to reject this hypothesis.

yellow colour, possibly  $\text{HgO} \cdot \text{AgI}$ . Such a compound would completely answer to the above description.

*Permanence of the Image after Treatment with a Developer.*—We have seen that, when the negative is placed in a reducer of iodide of silver, after a short washing, the iodide of silver is converted into metallic silver, which thus prevents any further change and formation of a combination of oxide of mercury and iodide of silver.

This operation does not appreciably alter the opacity of the image, and it is only by reflected light that the change in the appearance of the film can be discerned, a slight opalescence being no longer visible.

This after-treatment by a developer is therefore advantageous as ensuring the permanence of the intensified negative.

*Use of Sulphite of Soda as a Solvent of Mercuric Iodide.*—Having determined the most likely cause of the fading of negatives intensified with the mercuric iodide solution, we have endeavoured to find whether it would not be possible to find a solvent of mercuric chloride possessing reducing properties, and at the same time capable of being used in great excess of the mercuric iodide, by means of which this fading could be avoided.

We have found that iodide of mercury is freely soluble in a solution of anhydrous sulphite of soda, and that this solution is an energetic intensifier. Unlike thiosulphate, sulphite of soda can be employed in any proportion to the mercuric iodide without destroying the intensifying properties of the solution, since the sulphite has no solvent action on the intensified image.

Using sulphite of soda for this purpose, we have examined the intensifying action of mercuric iodide, and have made experiments on the permanency of the images.

*Formula for Intensifier with Sulphite of Soda and Mercuric Iodide.*—The best results are obtained by the following proportions of reagents:—

Mercuric iodide .....	1 part.
Soda sulphite (anhydrous) .....	10 parts.
Water .....	100 "

The image gradually gains opacity, taking a deep brown colour. The operation can be followed and stopped at the desired stage; it can be undertaken directly after fixation after a simple rinsing of the plate.

By diluting the solution or using less mercuric iodide slower intensification results, but the increase in opacity is always greater the longer the time of immersion.

On the other hand, quicker action results from an increased proportion of mercuric iodide so long as the limit of 2 parts of mercuric iodide to 20 parts of sulphite in 100 of water is not exceeded.

*Changes in the Intensified Image. Means of Avoiding them.*—We have already said that, if an intensified negative is digested in water for about twelve hours, it assumes a greenish-yellow colour, identical with that produced in the case of the thiosulphate intensifier, and due apparently to the same causes. This property seems to prove that the image alters under conditions analogous to those mentioned in reference to the mercury and thiosulphate formula. If, on emergence from the intensifier, the plate is washed in the usual way for from half to three-quarters of an hour, an image is obtained which becomes gradually yellow in a damp atmosphere, but in a dry atmosphere this change only takes place very slowly, and only becomes distinctly visible after several months.

The permanence of the negative can be improved by subjecting the plate to a bath of ten per cent soda sulphite as it comes out of the intensifier, followed by washing in the usual way; but this change can be absolutely prevented in another way, viz., by treating the plate with a reducer of iodide of silver. Any of the well-known developers answer this purpose: para-amidophenol, di-amidophenol, hydramine, pyrogallol acid, or hydroquinone. The silver iodide is converted into metallic silver, and no iodine is left in the film.

A plate thus treated may be left in water for an indefinite period without yellowing in the slightest, and even if the plate has not been treated with a developer, and has, in course of time, become yellow, the process can still be applied and the image converted into the metallic state.

*Reducing the Intensified Image.*—The intensified image can be reduced simply by immersion in sodium thiosulphate solution, the action of which, if sufficiently prolonged, is to reduce the opacity to that of the original negative, the only difference then observable being in the colour. If a developer has been applied, this method is obviously inapplicable, and one of the usual reducers must be used.

*Keeping the Solutions.*—Mercuric iodide solution in soda sulphite, as in soda thiosulphate, keeps well in a weak light. Otherwise it deposits mercurous iodide and mercury, and soon loses its intensifying properties. This change has suggested an investigation of the action of light on mercurous iodide with sulphite or thiosulphate of soda, which we are now following up.

*Theory of the Intensification Process.*—The theory of the process is very probably similar to that which we have stated in the case of thiosulphate. Mercuric iodide is obtained in solution, owing to the formation of a double salt of mercuric iodide and sulphite of soda, answering, if we may reason by analogy, to the formula—

or possibly by double decomposition, and the formation of sodium iodide,  $\text{NaI}$ , and a double sulphite of mercury and sodium,

In either case the action of the solution on the silver image is to first form mercurous iodide and silver iodide, the former being afterwards decomposed into mercury and mercuric iodide—

It may be, as we have intimated in the section on thiosulphate, that the mercuric iodide arising from the decomposition of the mercurous iodide forms sodium iodide and double sulphite of mercury and sodium. It is extremely difficult to confirm by analytical processes the predominance of one or other of these reactions, but, for the reasons before stated, this latter reaction is more probable, and the reaction is probably—

It is imaginable that the sulphite of soda acts on the iodine of the mercurous iodide, producing bisulphite and sulphate of soda and metallic mercury as per equation—

but the ease with which mercuric iodide is isolated from the liquid, and the facts that the quantity of sulphate does not increase, nor the liquid become acid (as would be the case if acid sulphite were formed) are arguments the other way.

*Use of Different Solvents in the Mercuric Iodide Intensifier.*—We have employed several solvents of mercuric iodide, viz., potassium iodide, ammonium chloride, sodium and potassium chloride. These, although (with the exception of the two last named) giving just as great intensification as sulphite or thiosulphate, possess the disadvantage of leaving the film in such a state that, when it is at all thoroughly washed, a yellow to red precipitate is thrown down on it, which we take to be a mixture of mercuric and mercurous iodide. The formation of this precipitate is due, no doubt, to the instability of the double salts formed by mercuric iodide and alkaline chlorides or iodides. The reactions which take place when these solvents are used in place of sulphite or thiosulphate are, however, precisely analogous to those prevailing in the case of these latter.

The equations will be as we have already given, and we have obtained evidence of the formation, from a mercuric iodide, of soluble double salts by acting directly with these solvents on mercuric iodide. In every case it proved possible to isolate and clearly identify the mercuric iodide. It should be distinctly understood that in no case is it possible to employ for intensification a great excess of the solvents in relation to the mercuric iodide, for a proportion of alkaline iodide or chloride of about 8 parts per 100, affects the gelatine, and, besides, incurs the precipitation of yellowish-red precipitate when the plate is washed.

*Conclusions.*—To summarise: The solution of mercuric iodide in sulphite of soda is the best form in which mercuric iodide can be used as an intensifier, allowing direct and visible intensification. Although the intensified images, especially if treated in a bath of soda sulphite, possess a fair stability, it is indispensable, in order to secure an image which will not yellow in moist air, to treat the negative with a developer.

LUMIERE FRERES AND SEYEWETZ.

#### PHOTO-ENGRAVING PRICES.

THE natural sequence to the appearance of any new and apparently profitable industry in the arena of trade is a tendency to overcrowding from the influx of other new traders.

Now, these newer firms must have orders, and in order to gain custom they must either offer greater advantages to the customers of established photo-engravers or seek in some way to gain a totally new clientele. The former is the most likely course, and there are open the alternatives of (1) better blocks at the same price as the older firms; (2) quicker work at the same price; (3) cheaper work of the same quality; (4) cheaper work of inferior quality.

Unfortunately it appears that nearly every new firm of photo-engravers adopts the policy of No. 3, that is to say, they offer blocks, the best of which are about equal to the average turn-out of the first-class established firm, but at prices materially lower.

Now, it is clear that a method like this cannot go on indefinitely; though to judge by the grumbles about bad trade, and rumours of process firms having a hard fight to make ends meet, this kind of thing has gone too far already.

I have no reliable statistics to judge by, but there seems to be less of a boom in photo-engraving than there was about 1892, when the enameline process promised such great things, which have not all been fulfilled. It seems that things will really be better and healthier now that it is discovered that process work is not the El Dorado it was supposed to be when prices were arbitrarily fixed by the pioneers of photo-engraving.

Every dog has his day, and the inventors and earlier workers in "process" have made good use of their day. They have survived the enormous drop in prices represented by the difference between the "good-old-times" price of 2s. 6d. a square inch and the present average of 7½d. a square inch. And why? Because it is probably true that with ample capital, well-appointed plant, and modern methods, a firm can make more profit now at 9d. per square inch than could formerly be made at the princely price of 1s. 6d.

This is because our present-day methods are much more scientific and certain, unlike those of the days when, for half-tone, albumen and bitumen were supreme, and there existed but an imperfect knowledge of the principles governing the action of the ruled screen.

But, still, the danger is that average prices seem to be getting beneath the point which improved methods can counter-balance, and this undercutting, it is certain, must stop somewhere, or ruin must be the ultimate result.

Now, photo-engraving seems just the kind of trade to be held well together by an association like the electrotypers and stereotypers have for the upholding of prices. But it might be more successful apart from these other trades, and the many provincial process houses should not be left out in the cold as they are at present. Methods of pricing should be kept up to date, that is, not a rigid fixed minimum for all sizes of plates, but the newer and fairer method of graduating the square-inch price in proportion to the size of the plate. In spite of the would-be reformers the square-inch pricing seems the most convenient and most likely to survive.

After all, commercial success in process work seems to be most likely attained under the following conditions: Ample capital; capable management; conscientious operators; prompt delivery; a fair price for good work, or refusal to undertake it; and this motto, framed in your office or in your heart: "Tis better to play for nothing than to work for nothing."

HAROLD W. HOOD.

## HOW I DID NOT PHOTOGRAPH THE METEORS.

FOR weeks the Press—common five-eight and scientific, yea, even and photographic—had been dunning into the ears—or should it be flashing into the eyes?—of its readers the great visions of ethereal flashlights that were to be seen in the passage of the Leonides (any friends of the "Ides of March?") from somewhere about the Plough and Leo, and I think the Pole star had something to do with it, to somewhere, or, more probably, nowhere. Even the man in the street was interested in this meteoric display which visited us over thirty years ago. That is always the way, familiarity breeds contempt; but, because it was over thirty years since we had this display, every one must needs be as solicitous as if some rich and ready-to-die relative was coming to visit us from some far-away country, to which he had gone when mother was a child, and his visit was with the evident intention of appointing one of us his heir.

Well, well, we are undoubtedly an imitative race, and I had to do as the others did. I aroused a lively interest in the various sky-high constellations, and by earnest study direct from the upper regions I have gained—a crick in my neck. It is hard work, if you are rather round-shouldered, studying astronomy. My enthusiasm in this newly discovered firework science overran my usual discretion, and in an unguarded moment I not only resolved to photograph these said Leonides, but I informed some other enthusiasts of my intention. Now, my friends consider me a "class" photographer, my figure studies and landscapes are invariably praised with an "Isn't that like?" or some other complimentary remark, while my attempts at architectural photography have attained to the dignity of "pretty." Editors of photographic papers in their omniscience, and Judges of photographic exhibitions in their autocratic power, have evidently discovered in me a possible and dangerous rival, for they steadfastly decline to acknowledge my photographic power, at least publicly, though they are bound to recognise it in their heart of hearts—how does the plural or singular come in now in reference to the almighty editorial WE?

By making a series of meteoric photographs—no, that would be better-worded, photographs of meteors—scientific men would be glad to acknowledge my photographic ability—scientific men are so truthfully truthful.

After reading any instructions I could get on the subject, such as focus on a distant object, use fastest place, lens at open aperture, expose plate and trust to the meteors crossing your "line of fire," &c., I went on the fateful night to a neighbouring height, with my camera and a full stock of plates. It was one of these clear, cold nights, just such a one as a pedestrian would choose for a good smart walk, while overhead "pale Luna shed her silvery light." Several other inquirers after knowledge were there before me, but none of them had a camera. Consequently you can see that amongst that devoted band of embryo scientists I was a man of some importance. "Focus on a distant object"—I focussed on the moon, and after I had it so sharp in focus that I could almost see "the man," I decided it would do, and, with the assistance of some of the waiting astronomers, I pointed the one-eyed watcher towards that part of the heavens between the Plough and Leo, at least we believed it was thereabout, and that was where the pyrotechnical display was supposed to start. I did not uncup the lens, as there were no signs of

out-of-the-way life in the firmament, nothing but the silent twinkle of the stars, and over all the kindly light of the moon. It was cold waiting; we walked about, smoked hard, danced, sung, and did, in fact, anything to try to disperse that piercing cold, while outside our noisy circle the world lay peacefully sleeping. Still no signs of these boasted messengers of fire; by-and-by one by one of our little band slipped away to "Blanket Bay," and a despondency fell on those left behind. As it was nearing two a.m., only my next-door neighbour and I were left, and the heavens were still in a state of quiescence. Human flesh and blood, even when protected by monster overcoats, could stand it no longer, and we regretfully left for home, having seen no meteors.

We had not, however, given up hope, but determined to "call again" at an early hour; so, after about two hours troubled sleep, we again journeyed to a point of vantage, accompanied by the camera; and as it was getting towards morning, or rather dawning, we both took our dogs with us, so that they might also experience the benefits of "early to rise"—you can perceive from this we were not selfish.

There on the hill-top, in the cold, clear November morning, stood these devotees of duty—two men, two dogs, and one camera—but in spite of the enthusiasm displayed, and the very evident thirst for phenomena, that phenomenon absolutely refused to oblige. By-and-by the factories in the valley began to twinkle with many lights, betokening preparations for the work of the incoming day. The moon sank below the eastern horizon in a blaze of golden glory, strangely in contrast with her silvery magnificence at midnight. The stars one by one disappeared, until so few were left that they looked more like signal lights than parts of a vast illumination.

From the valley at our feet came up the hum—that musical indication of many workers, toiling for daily bread. In the east we now saw the first gleam of returning day, faint and indecisive at first, but gradually gaining in power. Still we shivered, still the meteors most inconspicuously absented themselves. Daylight was at hand when we sorrowfully descended from our watch-tower to work-a-day world.

The memory of that night and morning still bring a shiver through at least two peaceful citizens, and meteors are distinctly "off" in their estimations. These plates, which twice ascended the hill of difficulty, are as yet unexposed, and in all probability the faith of the writer will hardly stand the test of thirty years waiting for the next display of Leonides. His faith in astronomical prophets has sustained a severe shock, not wholly attributable to cold.

ALLAN BLAIR.

## Our Editorial Table.

### THE "THISTLE" P.O.P.

Manufactured by H. M. Macfarlane, 30, Ravenscourt-gardens, London, W.

It is a tribute to the popularity of gelatino-chloride printing, that, although the process has been before the public for a good many years, new brands are constantly being introduced. The latest sample to reach us bears the distinctive name of the "Thistle," and the manufacturer, Mr. Macfarlane, informs us that he has had it well tried by some of the most expert photographers, who have reported favourably of it. So far as we have been able to judge from the sample sent us, the "Thistle" P.O.P. has been very carefully prepared, and yields results quite comparable to those we have seen or produced on other gelatine papers—of which, indeed, we have used not a few. The instructions for working the "Thistle" P.O.P. are as follows: Printing should be a little darker than the finished print is required. Before toning, wash for ten minutes in several changes of water. Toning.—Any of the usual formulæ may be used, but the following is strongly recommended:—

Sulphocyanide of ammonium .....	36 grains.
Chloride of gold .....	2½ "
Distilled water .....	20 ounces.

Toning will be complete in about five minutes; then wash for a few minutes and transfer to fixing bath: Hypo, 3 ounces; water, 20 ounces. Fix for ten minutes, and thoroughly wash in running water or several changes. The paper is sent out at the usual prices.

Messrs. WELLINGTON & WARD, of Elstree, have been good enough to send us their Almanac and Date Card for 1900. This handy and artistic daily remembrancer has been designed by George Walton, which is equivalent to saying that it is effective and in the best of taste. The firm state that all dealers and professionals who have not received a copy can obtain one on application to them. The Wellington Almanac is distinctly worth having.

### THE BYNOE LIMELIGHT JET.

Manufactured by R. & J. Beck, Ltd., 68, Cornhill, E.C.

The characteristic features of this jet are given in the following description of it by Messrs. Beck. It is intended for use with their New Luvex Lantern, or any lantern with overhanging body, where it is desired to use the limelight instead of the incandescent gas light. It is pointed out

that this is very necessary when a large screen is used, or when a lantern is used for demonstration in a partially illuminated room.

Lanterns of the above type do not admit of the use of ordinary jets, as they project beyond the back of the lantern, and, besides illuminating the room, are liable to get moved out of centre with the slightest touch. In the Bynoe jet there are no cog wheels to get clogged, and the adjust-

ments are simple and cannot get out of order. Screw-down valves are fitted instead of ordinary stop cocks, so that the gas can be regulated with the most delicate precision, and when once right there is no chance of it being accidentally altered.

The Bynoe Jet can either be supplied as a blow-through or as a mixed jet. The prices are as follows: Blow-through jet, 15s.; mixed jet, 17s. 6d.; tray for fitting to Luvex Lantern, 2s.

#### THE SANDELL CRISTOID FILMS.

Manufactured by Sandell Plates and Films, Ltd., Norwood Junction, London, S.E.

DURING the past few weeks reference has more than once been made in our pages to the new Sandell film, which its inventor has termed "Cristoid," and on December 8 we gave a brief outline of the process of manufacture. Cristoid, in fine, is a hardened sensitive gelatine film unsupported by any base, such as glass or paper, and it may be employed either in the out form for use in dark slides, or as a rollable film for daylight cartridge work. It seems to us that in the latest phase of film photography Mr. Sandell comes before the world with an exceedingly happy idea that is likely to meet with great success.

A considerable number of negatives made on the new film have been placed before us. These ranged in size from 12 x 10 down to half-plate, and the films were exposed both in dark slides and roll-holders. We do not desire to see anything finer in the way of photographic negatives. The films were of about the same consistency as rollable celluloid; they were perfectly flat and free from any objectionable curl, presented a smooth, even surface, and, examined by transmitted light, revealed an image without flaw. With such evidence of the qualitative results yieldable by Cristoid, we are justified in expecting it to win great appreciation in practice.

With a hardened gelatine film as the sole "support" of the sensitive layer, certain physical advantages are obviously assured as compared with other negative processes, viz., lightness, flatness, non-inflammability, coating on both sides (Cristoid is slow on one surface and rapid on the other), absence of halation and frilling. We append the principal instructions for the manipulation of the films:—

The out films may be exposed in any ordinary slide of book pattern without a carrier, if backed with a black card or piece of ferrotype plate, but the most convenient method is with the metal carrier, having the hinged rebate. N.B.—The films should be held by the corners, and not placed on the hand, as the moisture and heat inclined them to buckle; they, however, quickly resume their flatness when put down.

#### FORMULÆ.

##### Stock Developer One Solution.

Pyro catechin .....	1 ounce	or	30 grammes.
Potassium bromide .....	30 grains	"	2 "
Sulphite soda .....	4 ounces	"	120 "
Caustic soda .....	1 ounce	"	15 "
Boiled or distilled water .....	1 pint	"	600 c.c.

Dissolve each ingredient in the water in order given.

For standard solution take one part of stock developer and dilute with seven parts water, at temperatures of 55° to 60°, six minutes will be sufficient time, at lower temperatures increase the time or strength of solution; when sufficient density is not obtained in above time, under-exposure is the cause.

#### Formalin Bath.

Formalin .....	2 ounces	or	60 c.c.
Bromide potassium .....	60 grains	"	4 grammes.
Water .....	to 1 pint	"	600 c.c.

#### Fixing Bath.

Hyposulphite soda .....	8 ounces.
Water .....	1 pint.

Place first the formalin bath in a suitable size dish, a deep one by preference, and one large enough to take the enlarged film. Into the bath place the films one by one, allowing each to be covered and softened before adding the next, in this way six quarter-plate films may be treated in a half-plate dish. After the last film is immersed, keep dish moving for three to four minutes at temperatures between 55° to 60°, then replace bath in its bottle, drain and pour on (for six films) about eight ounces of standard developing solution. Turn the films over once or twice and keep moving for six minutes as before mentioned, wash in three or four changes of water and transfer to the fixing bath. The latter may be contained in any convenient wide-mouthed vessel, jar or bottle, and should be shaken from time to time and warmed if cold.

Washing if effected in running water is accomplished in half an hour. Should it be desired to restore negatives to the original size of film, this is easily effected by using a bath of methylated spirit after washing, then squeezegeeing.

To dry negatives they must be laid out and squeezegeed on pieces of clean French-chalked and dusted glass or ferrotype plate and set up to dry in a cool but dry place; if placed in the sun or a warm place, curling from the support will probably be experienced, necessitating another wetting and laying down. When quite dry, the negatives are easily stripped.

N.B.—If, in squeezegeeing, the shape of the film is interfered with at sides or ends by undue pressure, the shape is readily restored by pressing against the defective side with a straight edge such as a flat rule.

If it be desired to varnish the negative, a clean glass plate should be first coated with Cristoid varnish; when the latter is dry, the film is laid down as on plain glass and dried. Before stripping, the varnish film, outside edge of negative, should be cut through. If, before cutting the varnish film, the negative be painted over with varnish by means of a brush, a perfectly waterproof negative is produced.

In printing, which may be from either side, use a printing frame having a glass plate; at the back of paper a sheet of thin card should be placed and then a pad of felt to equally distribute pressure. The printing frame must not be placed in the sun. Should an unvarnished negative be injured by moisture or handling, it can be put right by squeezegeeing.

During the holidays we submitted the new Cristoid film to practical trial, and were much pleased with the ease attending its manipulation and the excellent quality of the pellicular negatives the process is capable of yielding. By the large section of the public with whom rollable film photography is a *sine-quâ-non*, Cristoid film will undoubtedly be welcomed.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, January 3, 1900. Open Meeting.

ROYAL PHOTOGRAPHIC SOCIETY.—On Tuesday, January 2, 1900, at eight p.m. Mr. Henry Spayer will give a lecture entitled, "Round about the Matterhorn and Aletsch Glacier," illustrated by slides from his own photographs. Ladies are specially invited to the meeting.

RÖNTGEN SOCIETY.—At the Ordinary General Meeting, on Thursday, January 4, at 20, Hanover-square, a paper will be read by Mr. Chisholm Williams on "The Interpretation of Skiagrams." Future arrangements are as follows: February 1, Dr. Hugh Walsham, "Röntgen rays in Diseases of the Chest." March 1, Mr. J. H. Gardner, subject to be announced later. April 5, Dr. Norris Wolfenden and Dr. Forbes Ross, "The Influence of the X Rays upon the Growth and Development of Micro-organisms."

At a meeting of the Ealing Photographic Society, held on the 18th inst., Mr. A. Ernest Smith attended for the purpose of awarding the medal, offered by the Society, for the best print, either direct or enlarged, and by any process, made from a negative taken at one of the summer excursions to Denham, Virginia Water, and Burnham Beeches, all the work to be that of the competitors. Seventy prints were sent in, besides a few not for competition. The medal was awarded to Mr. G. Fryer for a half-plate carbon print, and the Judge mentioned that the second best print was a quarter-plate carbon print by Mr. S. Stewart.

THE NATIONAL PHOTOGRAPHIC AND ALLIED TRADES' EXHIBITION, 1900.—The following is a list of the firms who have already booked spaces for the above Exhibition, which is to be held next spring, from April 27 to May 5: Marion & Co., London; George Houghton & Son, London; Thornton-Pickard Manufacturing Company, Ltd., Altrincham; Butcher & Son, Blackheath; Joseph Levi & Co., London; Cameras Limited, Manchester; C. P. Goerz, Berlin; Morgan & Kidd, Richmond; J. F. Shaw & Co., London; Spratt Bros., Hackney; J. J. Griffin & Sons, Ltd., London; O. Sichel & Co., London; D. A. Lowthime, London; Lonsdale Bros., Hornsey; Benettink & Co., London; Tella Camera Company, London; William Tylar, Birmingham.

Warwick Trading Company, London; Levi, Jones, & Co., Ltd., London; J. Lizars, Glasgow; Dawbarn & Ward, Ltd., London; Camera Construction Company, London; Lumière et Fils, Lyons; Bessus & Co., London; H. W. Cox, London; Monroe Camera Company, London; Photo-chromosome Syndicate, Ltd., London; Secco Films, Ltd., London; Gaumont & Co., Paris; Wallis Bros., Kettering; Iliffe, Sons, & Sturmer, Ltd., London; A. C. Jackson, Hackney; Hepworth & Co., Walton-on-Thames; T. P. Bethell, Liverpool; Films Limited, Manchester; *The Photogram*, London; *Photography*, Coventry; *The Photographic Dealer*, London; Process and Engineering Company, London; H. Purser, London; Moulton Bros., London; Mutoscope Syndicate, Ltd., London; J. E. Lockyer, Deptford; Rathenow Optical Company, Rathenow.

## Patent News.

THE following applications for Patents were made between December 11 and December 16, 1899:—

**DARK SLIDES.**—No. 24,692. "Improvement in Photographic Film-holders (dark slides)." J. R. GORTZ.

**CINEMATOGRAPHY.**—No. 24,726. "Means for Regulating the Speed of the Positive Film whilst in motion in Cinematographs and like apparatus for Optical Projection." E. J. MAREY.

**DIPPERS.**—No. 24,744. "A new or improved Device for Dipping and Holding Photographs in the Developing Bath." T. E. C. WILSON.

**LENSES.**—No. 24,720. "Improvements relating to Photographic Lenses." Complete specification. T. R. DALLMEYER.

**APPARATUS.**—No. 24,884. "Improvements in Apparatus for taking Photographs." F. DE P. ROMANI.

**APPARATUS.**—No. 24,896. "Improvements in or relating to Apparatus for Taking and Exposing Photographic Pictures." Communicated by P. A. J. GASSA. A. J. BOULT.

**ACETYLENE.**—No. 24,963. "The Application of Acetylene Gaslight for Photographic Printing and Lithographic Printing, and the like." M. JACKSON AND A. J. C. JACKSON.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
1.....	Cripplegate Photo. Society .....	Lantern Night.
1.....	South London .....	Winchester Excursion. J. T. French.
1.....	Stafford Photo. Society.....	Technical Control for Pictorial Results. Reader, H. E. Burn.
2.....	Bristol and West of England ..	Elementary Technical Instruction Meeting. ing: <i>The Negative</i> . E. Brightman.
2.....	Gospel Oak .....	Social and Exhibition of Members' Work.
2.....	Hackney .....	Members' Lantern Evening.
2.....	Isle of Thane .....	Social Evening.
2.....	Redhill and District .....	Negative-making. F. Martin Duncan.
2.....	Royal Photographic Society ..	Round about the Mottelhorn and the Alps. Glacier. Henry Speyer.
3.....	Ashton-under-Lyne .....	Sale of Illustrated Papers and Magazines.
3.....	Borough Polytechnic .....	Country Life. R. R. Hawkins.
3.....	Croydon Camera Club .....	The Preparation of Negatives for Printing. ing. Francis T. Beeson, F.R.P.S.
3.....	Photographic Club .....	Open Meeting.
3.....	Southsea .....	Toning Processes. F. J. Mortimer.
3.....	Woodford .....	Horse Lens is Made. C. P. Goetz.
4.....	Camera Club .....	John Chinaman as seen by John Bull. Rev. Hugh M. Eytton-Jones, M.A.
4.....	Darwen .....	Lecture: <i>Negative-making</i> .
4.....	Leeds Photo. Society .....	The Camera as an Aid to the Study of a River. H. Crowther, F.R.M.S.
4.....	Tunbridge Wells .....	South African Slides, lent by the Union Steamship Company.
5.....	Borough Polytechnic .....	Practical Evening: <i>Modification of Lenses</i> .
5.....	West London .....	Demonstration: Carbon. J. Brown.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 21.—Mr. T. E. Freshwater in the chair.

The CHAIRMAN laid before the meeting a form prepared by the Photographic Copyright Union, protesting against the proposed new Copyright Act, by which photography is deprived of its old status as one of the fine arts, under the existing Act (1862), which it is proposed to supersede. The Copyright Union requested the support of this Association in opposing Lord Monckswell's new Act now before the Lords. Under the new Bill copyright is only called into being by the registration of a photograph, and, if this is not done within six months, all right to protection is entirely lost.

Mr. PHILIP EVERITT said that, on the other side, it was not fair that a man who deferred the protection of his work by registration until the picture became of value should have protection on the same terms as if registered at the proper time set forth in the new Act. The existing Act was one-sided, and required amendment in many particulars.

Several speakers took exception to the views of the last speaker, and instances in illustration and support of either side were given at length.

The Chairman's signature to the document was duly authorised by the meeting.

Mr. MACKIE referred to Lumière's iodide of mercury and anhydrous sodium

sulphite intensifier, which was analogous to Edwards's intensifier, although the latter employed hyposulphite of soda in place of the sulphite of Lumière's formula. The advantage of the new formula was that the negative treated would not so quickly change as did those intensified by Edwards's method, and any chance of this could be quite eliminated by subsequent redevelopment, which left the image in a permanent form. Mr. Mackie had bought a bottle of the intensifier, one ounce for 1s., but he found it stated that, by purchasing the separate salts, eleven ounces of the mixture could be acquired for about 3s.

A discussion took place regarding new and old developers, and it was said that, while pyrogallol could not perhaps be beaten in its results, ortol was very near its equal. The advantage of the latter was that there was no staining of the fingers or plate, and several plates could be developed without renewing the solution. Ortol is three times the price of pyro, and, if by the former six plates could be developed, it resulted in ortol being half the ultimate cost of pyro.

Mr. EVERITT called attention to the fact that R. E. Liesegang had stated that stale pyro developer diminished the evils of over-exposure. He used a solution that had been employed six times before, and found that the negative was far better than it would otherwise have been. Bromide would only have retarded the development, but the stale pyro corrected the excessive exposure.

### PHOTOGRAPHIC CLUB.

DECEMBER 20.—Mr. J. R. Williams in the chair.

The HON. SECRETARY laid before the meeting a document submitted by the Photographic Copyright Union, protesting against the new Artistic Copyright Bill which is before the House of Lords. The new Act would expel photography from the fine arts, amongst which it has been classed since the Act of 1862, and place it altogether in a debased position. It was unanimously decided to support the protest set on foot by the Union, and the Chairman's and Secretary's signatures were duly appended to the document.

The HON. SECRETARY read the Affiliation Lecture,

CHEMISTRY AS IT CONCERNS PHOTOGRAPHERS,

by Mr. C. F. TOWNSEND. After commenting upon the extent to which theories advanced for the explanation of natural phenomena have been of service in laying bare the secret workings of nature, the author proceeds to inquire into them as applied to bodies such as water, air, and other familiar surroundings. Directions for experimental proof of theories are given, and considerable attention is given to the metal silver which plays so important a part in photographic practice. The effect of light, reducing agents, and solvents of its salts upon the various forms it takes, were explained in an elementary and instructive manner, which was fully appreciated by the meeting.

**Croydon Camera Club.**—The Christmas-card competition, which was entered into with some spirit by a section of the members, ended in the medal being awarded to Mr. Ben. E. Edwards, with a clever set of snow and ice scenes arranged upon a suitable card. At the request of the Council, Mr. EDWARDS gave an interesting lantern lecture on Wednesday, the 20th inst., explaining his procedure in the exposure of lantern slides. A large number of examples, exposed and developed under different conditions, were shown on the screen, the main deduction being that, given a sufficient exposure, four or even eight times the normal might be employed without serious harm, resulting providing development were stopped early enough. The plates used were Thomas's, to which the above remarks apply. A number of slides by the following members were shown, some of which will be included in the lantern entertainment at the Public Hall on the 17th prox.: Messrs. Rogers (eclipse studies), Andrews (camp life), Myrtle, Kough (snow scenery), Edwards, Watson (Gloucestershire scenery), Maclean (military on the march). Amongst those shown by the last-named was a slide from a plate exposed in June 1897. It was not developed until two years and a half after exposure, and, although the plate was an extremely sensitive one, the negative turned out quite satisfactory, as evidenced by a very brilliant lantern slide. The negative referred to was taken on an Imperial flashlight plate.

**Richmond Camera Club.**—At the meeting on the 18th inst. a paper by Mr. J. A. Hodges was read, in which the pictorial treatment of lantern slides was dealt with. Mr. Hodges advocated the use of a piece of very finely ground glass or matt celluloid, which should be fixed on the back of the negative, and on which, by means of finely powdered plumbago, the parts that printed too deeply could be strengthened. A collection of slides, showing negatives before and after treatment and the resulting lantern slides, accompanied the paper, and in many cases proved the correctness of Mr. Hodges' statements.

### FORTHCOMING EXHIBITIONS.

1899.	
Dec. 29, 30 .....	Borough Polytechnic Photographic Society. Hon. Exhibition Secretary, E. J. Hoar, 59, Hillingdon-street, S.E.
.. 29-Jan. 1900 ...	Huddersfield (Invitation). W. A. Beevers. Cloth Hall-street, Huddersfield.
1900.	
January 29-31.....	Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.
February 10-21 .....	Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.
March .....	South London Photographic Society.

April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE METRIC SYSTEM.

To the Editors.

GENTLEMEN,—I am glad to see the BRITISH JOURNAL OF PHOTOGRAPHY joining in the attempt to further the use of the decimal system as applied to weights and measures. Apart from the more scientific aspect of the question is, perhaps, the much greater facility it gives for the calculation of quantities, and it has always being a matter of surprise to me why educated men, like photographers and pharmacists, should so long have hesitated to adopt it, and even now I fear the majority still adhere to the old and irrational system.

On casting about for a reason why this should be so, I have come to the conclusion that it is on all fours with what occurs when an Englishman tries to learn (say) French; instead of learning that language as French, he instinctively turns it first into English, before he can make any thing of it, which is, of course, absurd. It would be just as reasonable when reading an English book to attempt to get at its meaning by turning it into French, or *vice versa*. There are many expressions and phrases in both languages that it is not possible to translate literally.

In like manner, when a man who is used to the old system of weights and measures wants to adopt the new metric system, what does he do? He says: Oh, a gramme is 15.432 grains, and he takes out his grain weights accordingly; or, if a cubic centimetre, he says: Ah, that equals the weight of a gramme, and corresponds to about 17 minims, and out comes his minim measure. But then he cannot be quite exact, because, just as certain idioms in French have no exact counterpart in English, so the decimal points in the two systems come in as a disturbing factor.

It is very common now, both in pharmaceutical and photographic literature, to employ both the systems, and, if only the followers of either pursuit would get a set of metrical weights and measures, and use them as such at every available opportunity, more than half the battle would be overcome; and, if the authors of formulae would only express them according to the metric system, instead of the utterly absurd proportions now given, the other half of the difficulty would disappear. Captain Abney has set a good example in his *Instruction in Photography*.—I am, yours, &c. J. H. BALDOCK, F.C.S.

### DOES BACKING SLOW A PLATE?

To the Editors.

GENTLEMEN,—Re your report of meeting of Photographic Club. It appears to me it would have been better to have named the subject of "Plate Backing" at the time of the lecture. And how does the Chairman know that a "many people," &c.? I suppose I reminded him of the many people. I may inform him that my conclusions were drawn from practical experience had under "decent conditions." I should have been glad if my slides, which I had prepared specially for the occasion, had been shown under "decent conditions," instead of the wretched rag used for a screen. My slides were spotless. An artist present offered to touch them up and spot them for me before I showed them again; the faults, of course, were in the sheet. Much time was wasted in reading minutes, &c., which not a soul listened to, and then discussion was invited—time wasted, which might have been devoted to rearranging the screen. I think my name had better have been left out of the report of the meeting. The Chairman, I am aware, is very learned, but I prefer experience to theory.—I am, yours, &c.,

9, Baker-street, Portman-square, W.

THOMAS FALL.

### ORTOL.

To the Editors.

GENTLEMEN,—Mr. Welford's articles on ortol seem to have produced some controversy as to its value as a developer; it appears to me that the question is one of economy over pyro, but at what cost? the falling off in quality if used repeatedly. Each plate developed induces additional restrainer, and needs increased time in development; these disadvantages are detrimental to uniform results. I have experimented with all the various developers, and, in comparison with

our old friend pyro, prefer its use. I consider it cheaper in the end, by securing uniform results with a uniform developer. You speak of temperature as an important factor in satisfactory results; in cold weather I always make this a great consideration, and generally start at 70; but finding that after completion of development the temperature is reduced to 60°, to prevent this, I warm the dish and retain the same temperature throughout.

Mem.—I find that after using ortol it has a peculiar effect on my skin for days when I use soap, similar to washing in very hard water.—I am, yours, &c., PYRO.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

S. W. MARCHANT.—Many thanks for the correction, which shall be duly noted.

FLASHLIGHT.—J. OSMAN. The compound, according to the formula enclosed, will give a very brilliant light, which is very actinic and well suited to your purpose, but we give you a word of caution: The mixture is a very dangerous one to deal with. Its components are harmless enough by themselves, but when mixed together the case is just the reverse. Dry and powder the ingredients separately, and mix them together in small quantities as required for use on a sheet of paper, using a piece of cardboard as a spatula.

STUDIO DESIGN.—BEGINNER writes: "I propose building a studio in my garden in the spring against the side south wall of the house, so that the only light I shall get will be from the direct north. I enclose three rough sketches (please excuse their roughness, but I think they, with the proposed dimensions, will give the idea) of what I propose. What I should like your opinion on is, which of the three would be the best?"—Decide upon "B," but do not carry the glass up to the top. Make the upper two feet six opaque, and you will have an excellent studio.

FRAUDULENT COPYRIGHT MARKING.—N. B. writes: "A photographer here is in the habit of marking the portraits he takes of his sitters in the ordinary course of business, and for which he has been paid, 'copyright.' I happen to know that he does not register them at Stationers' Hall. If he did, I doubt if the copyright would be good. What I want to know is whether he can legally mark a photograph copyright when there is no copyright in it?"—Certainly not. It is illegal to do so, and is a fraud as much so as to stamp anything "patent" when it is not patent, the penalty for which is very heavy.

A QUESTION OF DEFINITION.—R. J. says: "We enclose you a rough proof of gasometers recently taken by us for a firm in the north. They refuse to accept the picture, saying it is out of focus. We say it is sharp as a needle from end to end. They reply, 'The picture can be as sharp as a needle from end to end, and still be out of focus.' Will you oblige us by giving your valuable opinion on the subject in your paper, as we fail to see how such a thing is possible."—In reply: We quite agree with your customers that the photograph is out of focus, otherwise the lens gives very imperfect definition. You say the picture is "as sharp as a needle from end to end," whereas it is not sharply defined anywhere. We should say that you ought to supply a picture with finer detail for the purpose they, doubtless, require it for.

DISPUTED ACCOUNT.—Z. A. says: "A lady and her daughter sat for their portraits, a dozen cabinets each. I sent them each two proofs (good portraits); they did not like them. They were retaken, and still not liked. They both sat four times, and one five, before they were pleased. When I sent in the account for a dozen cabinets each at my usual charge, they disputed payment unless I made a considerable reduction, as it put them to inconvenience to sit so many times. On my saying that, if the amount was not paid, I should be compelled to proceed in the County Court, they said they should plead a set-off for their trouble. What is your advice?"—Proceed, decidedly, and you will recover. Produce proofs of the rejected portraits, and it will show the futility of the sitters and the trouble you went to to please them. We never heard of a case of this sort before.

STEREOSCOPIC PHOTOGRAPHY.—B. HOLMES writes: "On reading your excellent and comprehensive article on 'Stereoscopic Photography' in the ALMANAC for 1900, I see you mention a particular stereoscope for transparency workers, viz., fig. 4, page 670. I would esteem it a great favour if you would inform me if this sort of stereoscope is on the market, or if I could get one made at any particular firm, or any hints regarding it. I am very much interested in stereo-photography, having been working at it for a couple of years now, both in paper and transparencies, and admire it more than any other photographic process."—In reply: The instrument referred to was devised many years ago by Sir Howard Grubb. So far as we know, it is not obtainable commercially. We wish we could be instrumental in persuading apparatus-makers to take up the manufacture of many of the older forms of stereoscopes.

### LANTERN MEMS.

GREETINGS to all lanternists and readers of these "Mems." for a healthful and happy New Year. It is usual, at the beginning of the year, to reflect on the past and make resolutions for the future. How many of us are satisfied, I wonder, with the retrospect? So many ideas conceived and not put into practice, experiments started and not completed, and improvements projected without being carried to a successful termination. However, with all these shortcomings, no doubt a fair proportion of good and practical work has been done, and the end of the year has found us better informed, more advanced, and in possession of improvements in apparatus and methods of working that will be useful in 1899.

To look back over a period of thirty years does not seem so very long, and yet this is the time I have been connected with lantern matters and optics; but to look forward one year is such an uncertain quantity that one has misgivings and doubts about seeing it through. If the world is not moving any faster than it used to years ago, certainly the people on it are, and, if the race is to the swift, we shall all have to be provided with auto-motors to keep pace with the developments that are occurring in all branches of science. The more one knows, the greater one feels one's comparative ignorance and the necessity to be up and doing. I often envy youth, with its boldness, and assurance, and satisfied airs, for they think there is no necessity to reflect, and are perfectly content with what is, without worrying about what will be. The "rude awakening," however, comes to all, except, perhaps, the self-conceited, and even they, by sheer rebuffs or experience of the world, are obliged to acknowledge, to themselves if not to others, that there is something that they might still learn with advantage to themselves.

HARKING back to the time I first had to do with optical lanterns, one can by comparison see the enormous advances made in their construction and the development of accessory apparatus, also the remarkable influx of traders into the industry. This, no doubt, is largely due to the popularity of photography as a pastime, and the facility with which lantern slides can be produced from one's own negatives; also the interest taken in all matters of travel and the desire of those who have visited "fresh fields and pastures new" to impart knowledge respecting same to others by exhibiting views of

the natural features of the country, buildings, and the people. To do this a lantern is necessary, and now hundreds trade in lanterns where only a few did in the sixties.

THE cinematograph, notwithstanding the restrictions imposed by the London County Council, is still very much to the fore, and recently I had an opportunity of witnessing the working of the "one-turn-one-picture" cinematograph. Certainly, as far as the mechanism was concerned, it left nothing to be desired, for a more clever application of sound movements and mechanical principles could hardly be conceived. In the result, it is possible to show a series of animated pictures as usual, and stop at any particular place and instantly reverse, the gearing being perfectly automatic, the simple act of turning the handle controlling it all, for on turning the reverse way, the ordinary gear goes out of action and the reversing movement comes into play. Pictures, such as soldiers marching, men diving, &c., are particularly suitable for this machine, for a dead stop or reversal can be instantly made.

BESIDES this important mechanical action, the machine has spools for the films large enough to take a number of subjects connected together, and can be enclosed in a metal case as now required when shown in public halls. It also has a fireproof safety fitting, so that it is not possible, even if the heat rays from the light are concentrated on the film, for more than one small circle in one picture to fire, and this at once goes out when the metal screen or support is reached. The intermittent action is also very good, and gives the least possible strain on the film, ensuring steadiness and certainty of movement. Altogether it is a high-class and practical machine.

ANOTHER novelty recently put on the market is the Birtac, a miniature machine for taking and projecting animated photographs, and, from what I saw at a special demonstration recently given by Mr. Birt Acres, there should be a good future before this *bijou* apparatus. Certainly the films shown were wonderfully steady. As the sensitive films used in taking the pictures are very inexpensive, subjects should be obtainable in a good light that will be enjoyed by the family circle afterwards. The light used for the projection apparatus, which forms part of the outfit, is incandescent gas, with a special small-size mantle. Of course, with this light, only a small disc can be obtained, but it is large enough for home use in a properly darkened room. As the whole apparatus, including camera, with good lens and daylight changing film-holders, lantern projector, and printing and developing apparatus, can be purchased for twelve guineas complete, it should be popular.

THERE is one thing of very marked interest to those who use, or desire to use, cinematographs, and that is the safety in use of this little apparatus, for, with the incandescent light, the heat rays are

not sufficiently great, nor do they come to a focus on the film, to fire it, and the films are on spools enclosed in covers. The whole is very portable, and requires very little technical knowledge to use it.

DR. GEORGE STOKER has for some years been experimenting in the healing of old ulcers and other forms of wounds, which are very tedious in the matter of repair, and very "callous" as regards any tendency to heal at all, by means of surrounding the part with an atmosphere of oxygen gas. His success has been undoubted, and he has contributed to medical science a valuable aid in a department of practice singularly disappointing, as a rule, to the surgeon. Dr. Stoker's latest account of his labour indicates that he regards this action of the oxygen, as directed, to form an antitoxin, or corrective principle, from the germs which are present in the non-healing part. He has proved this, scientifically, by passing oxygen through a culture of the germs, and by using the culture as an application of the wound. In this case healing proceeded as when oxygen was used directly. A great future should lie before this mode of encouraging the healing process. Dr. Stoker originally got this idea of the treatment from his experiences among savage tribes, which expose their wounds freely to the pure, germless air of their native hills.

As the Hungarian Patent Office does not publish any official gazette containing a record of the patents issued in that country, a journal has recently been established with a view to supplying this want. This journal is printed in four languages—Hungarian, German, French, and English. Some of the English descriptions are unique. We give below a specimen of the translations:—"PROCEEDING AT THE PRODUCTION OF STOCKINGS OF THE LIGHT WITHOUT FLAME OF SPONTANEOUS IGNITION.—*Claim*: Proceeding at the production of stockings of the light without flame of spontaneous ignition without use of heaters or putting-in of lighters, characterised by a stocking of light without flame of a provenience whatever prepared in such a manner after it's treatement in an alkalie bath by impregnation of one portion of its surface by platina—or iridium—salts, that these salts form ethiops of platina or iridium or the oxydes of incandescence—oxyde of thorium or cerium, &c.—causing the ignition of the stocking at the contact with the mixture of gas and air."

THE Elliott Cresson medal has been awarded to C. Francis Jenkins, for the invention of the phantascope, on the recommendation of the Franklin Institute, after a searching examination of this instrument.  
G. R. BAKER.

#### THE DETERMINATION OF WAVE-LENGTHS.

At the present moment, when so much attention is being directed to colour photography, it may not be out of place to summarise an extremely useful paper by Messrs. Edser & Butler on the above subject.

The determination of the wave-length of any particular spectrum line, or the absorption of any solution or glass to anything like accuracy, is by no means an easy task for those who have not some experience with the spectroscope and the various methods of calibrating the same.

I need hardly point out that there are two principal methods of determining wave-lengths—the one due to the reference to what I may call a chart in which the position of certain lines is, absolutely known, the said chart being projected simultaneously upon the sensitive surface whether this be the retina or the photographic plate; the other method is to employ graphic interpolation by means of a curve, and this is the more accurate the greater the number of Fraunhofer lines which are primarily determined.

When one considers that, although the number and relative positions of the spectrum lines of any substance are always absolutely the same under given conditions, yet that the apparent position of the same varies with the slightest change in the adjustment of the spectroscope, and, speaking broadly, is never the same for any two spectroscopes, no excuse is required for bringing forward the work of the above-named experimenters, and it is to be hoped that some one will shortly place in its complete form their extremely simple idea upon the market.

Taking advantage of the production of interference bands by a film of air between two silvered glass plates placed in front of the slit, they

obtain a scale which may be photographed once for all and kept for future reference, or else the scale may be photographed or used each time.

Their exact method of procedure is to obtain two pieces of good plate glass, and their surfaces should be silvered somewhat heavily by the milk-sugar process. The silvered surfaces are placed together, a little soft wax being placed at the edges to allow of the distance being adjusted, which is done by viewing a spot of light or incandescent electric lamp filament through the silvered surfaces, and pressure applied to the edges till the multiple images coincide. Then, on viewing a sodium flame through them, interference bands will be seen, and the glasses should be adjusted till they are as broad as possible, and they should be viewed at as great a distance as possible, as the perfection of the final results depends to a great extent on this adjustment.

The plates are placed in front of the slit of the spectroscope, and preferably with the slit parallel to the bands, when the spectrum will be seen to consist of bright lines separated by almost black bands. The authors state that using the arc light rendered slightly convergent by a lens as close as possible they proceed as follows for photographic purposes: "We have adopted the plan of covering either the upper or lower half of the slit with a piece of black paper stuck on with soft red wax before placing the plate in position. The necessary exposure will vary from about half a minute to three seconds (using Edwards's snapshot isochromatic plates), according to the nature of the spectrometer employed. It is well to introduce a little common salt into the arc while this exposure is being made, as thus the D lines, as well as the H and K lines, will be superimposed on the bands. Another piece of black paper having been placed so as just to cover the exposed half of the slit, the first piece is removed, and the spectrum which it is wished to examine is photographed."

Every fifth or tenth band can be marked starting from the red end and the whole numbered, and, this being done, the following is the method of determining the wave-lengths, using the D and H or K lines as the data. The equation used is—

$$n = \frac{m\lambda_n}{\lambda_0 - \lambda_m}$$

Scale No. 90.2

Wave-length, 5328.5 ( $\lambda_n$ )

" " 402.3

" " 3908.6 ( $\lambda_m$ )—

then  $m = 402.3 - 90.2 = 312.1$

$$\lambda_0 - \lambda_m = 1359.9$$

hence

$$n = 910.8$$

To find the wave-length of the line whose scale number = 371.2

$$\lambda = 371.2 - 90.2 = 281$$

then

$$\lambda r = \frac{n\lambda_0}{n+r} = \frac{910.8 \times 5328.5}{910.8 + 281} = 4072.2$$

Using this method it is possible to determine with the aid of an ordinary pocket magnifier the position of any given line to within one-tenth of an interference band, and from a table given by the authors it is possible to determine the wave-length to within an error of plus or minus 0.5 tenth-metres.

When a large number of wave-lengths have to be determined, a graphical method may be employed on divided paper, by plotting the frequencies vertically and horizontally; mark off the scale divisions vertically, starting from zero along the horizontal axis, and to mark off vertically above their respective scale divisions the frequencies of the two standard lines, joining the extremities of the latter by a straight line, and the frequency of any scale number is read off directly. The accuracy of this method is equal to the former.

If the reference interference scale is once photographed, it is unnecessary to do this with every spectrum, provided the adjustments of the spectrometer are not altered and the D lines are present in every photograph. The photographic scale is then placed with its film in contact with that of the photograph bearing the unknown spectrum, and, the D lines being brought into coincidence, the procedure above described is gone through.

A. D. PRETZL.

#### SOME NOTES ON STEREOSCOPIC SIZES.

It certainly seems to me a curious coincidence that during the last few weeks the subject of my article in the ALMANAC, i.e. stereo cameras and plates, has also been brought forward in these pages. Formerly I considered the subject a buried one; that was my reason for calling attention to it, and I am pleased to find that others besides myself consider the subject worthy of discussion; it clearly proves that the interest in stereoscopic matters is slowly but surely reviving.

I am not one of the old school, and cannot write of what I used forty years ago; historical matters, then, I will lay aside, and look at things of to-day. We have at least three sizes being used for stereoscopic work, viz.,  $6\frac{1}{2} \times 3\frac{1}{2}$ , half plate, and double quarter. It is also interesting to note that in France they also have three sizes, viz.,  $9 \times 18$ ,  $13 \times 18$ , and  $15 \times 21$  centimetres, in every-day use, and on two occasions I met with the  $12 \times 16\frac{1}{2}$  cm. being used for binocular work.

A few notes after two years' continuous working with one or other of the six sizes may be of interest to those who contemplate taking up this interesting branch of work. During my recent trip to the East I used two sizes only, both of which were French— $9 \times 18$  and  $13 \times 18$  centimetres, but for my own private work I favour the English "double-quarter," for reasons set forth in the ALMANAC.

The size I dislike most of all, and shall never use again, is the  $9 \times 18$  cm. ( $3.7 \times 7.0$  inches), which is nearly the same as our recognised stereo size,  $6\frac{1}{2} \times 3\frac{1}{2}$ . It may be gathered from this that I consider our "stereo" plate unsuitable, and for the simple reason that it allows of scarcely any trimming. Over and over again our artistic authorities tell us that pictures should be taken on plates large enough to allow of ample trimming. Does not the same rule apply to stereo and lantern slides, or are only those productions considered pictures that are fuzzy, foggy, and enlarged, or printed in mud—I mean gum?

I read in these pages a few weeks ago that some one advocated a stereo hand camera of the size mentioned, and also wondered very much why they were not more generally used, especially as half of a stereo slide was lantern size. Just so, but is it wise to take a lantern slide (or the negative) exactly the size a finished slide is to be? I should say not. It may be argued that masks serve the purpose of trimming. They may do to a certain degree; that, however, is not sufficient. Stereo pictures vary little, and masking, generally speaking, is not possible, hence the advisability of having a larger negative from which to select the choicest part for the stereo card.

What is the size of a stereo print? some may ask; and on looking through my collection I find I have four different makes—first, a French make,  $2\frac{1}{2}$  in. square; second, an American make,  $3\frac{1}{4} \times 3\frac{3}{4}$  in.; third, an English make (private),  $3 \times 4$  in.; and, lastly, some of a well-known English maker, who sticks to no regulation size but varies them. One of his slides is  $3\frac{1}{2}$  in. square, another only  $2\frac{1}{2}$  in., whilst some cards contain one of each, the right side being, as a rule, the largest.

Successful hand-camera work is at all times difficult, and that of stereo hand-cameras specially so. I do not say good results are not sometimes obtainable, because they are; but the utter failures are in a large majority, and, in the hands of a beginner, such would at once condemn stereoscopic work. The artistic and stereo qualities of the picture, be it remembered, are made or ruined in a small compass upon the finder, there being no  $12 \times 10$  plate to cut the square from. Hence the great care necessary.

The other size I used in the East ( $13 \times 8$  cm.) is very good indeed, and allows of ample trimming; but, as I have intimated elsewhere, of all the sizes now upon the market I prefer "double quarter."

RICHARD PENLAKE.

## SOME RECENT EXPERIMENTS IN FLASHLIGHT WORKING.

### II.

DURING recent years there has been a distinct tendency to employ flashing compounds prepared by mixing in varying proportions pure magnesium with gunpowder, also pure magnesium with chlorate of potash, as well as mixing sulphur with magnesium powder; and, considering the highly dangerous nature of these mixtures, it is surprising that such a procedure should be persisted in, especially when it has been conclusively proved that in pure magnesium alone lies all that is required for the successful accomplishment of flashlight working.

The mixing of one or other of the above ingredients with pure magnesium is, no doubt, prompted by a desire to consume all the magnesium powder, as well as to cause as brilliant a flash as possible in the briefest possible space of time. In the case of using gunpowder, for instance, any one who for the first time tries a mixture of such with pure magnesium will be forcibly impressed by the sudden nature of the combustion that takes place in comparison with what would be obtained by burning the same quantity of pure magnesium in a gas flame, or a flame emitted from the combustion of methylated spirits, the duration of the flash being not more than about one-third of the time occupied when the gunpowder is used in combination with magnesium.

This rapidity in combustion has been looked upon by some workers as a matter of importance when the light has been employed for the purposes of portraiture; but, when all is considered, there would appear to be very little, if indeed any, advantage when the very brief space of time required for pure magnesium being consumed is fully estimated. At least, in the writer's experience of using the flashlight in a pretty wide range of portraiture, there never was any difficulty experienced in not obtaining a sufficiently rapid flash of light; whilst in numerous other branches of photography the aim has always been in quite the opposite direction, i.e., to obtain a flash of the longest possible duration.

There have been certain forms of apparatus, however, constructed and

placed upon the market which, being specially designed to burn these compound mixtures, no doubt have led up to the practice of such being employed, even when a perfect knowledge of the danger attending such was well understood, and, every now and again, accidents which are clearly traceable to the employment of these dangerous mixtures are reported, the latest being of an alarming nature which took place in the South of England a few weeks ago.

Accidents have also happened through the admixture of sulphur and pure magnesium—a very striking instance of which occurred during a demonstration given before one of the photographic societies in the West of Scotland, and of which it is safe to state that not one individual who had the misfortune of being present on the occasion would ever dream of using such a mixture in future. The use of sulphur in conjunction with magnesium powder produces a light of extraordinary brilliancy, and, no doubt, enables every particle of the mixture being utilised in the flash, and, were the same free from the danger of exploding, would prove a most valuable compound to use in some instances of flashlight working, as may be proved by any one mixing a small quantity of such in a tin patty pan, say in the proportions of three parts of magnesium to two parts of flowers of sulphur, or thereabouts, firing the same by means of a lighted taper, or dropping a lighted fusee into it. This gives a flash of great actinic value in photography, and is somewhat slow in burning. It is, however, not a compound that can be manipulated with impunity, and should only be used when every possible precaution is taken to guard against accidents, and under no conditions should it be used in closed chambers of flash lamps.

If a compound of sulphur and pure magnesium has to be employed in such cases as dark interiors, where it is desired to light up a considerable area or space, proper provision should be made for burning the same in open vessels, such as cast-iron pans, placed in suitable position to each other, and firing the same by means of a lighted fusee attached to a long stick. Of course, a mixture of this kind is much more economical than pure magnesium alone, and the light is very good indeed.

With some operators working on wide subjects, no matter what form of lamp or light is being employed, there has always been a difficulty experienced where more than one lamp or light is concerned in getting all the lamps to fire simultaneously; this is, no doubt, a matter of considerable importance where moving objects are concerned; but of little moment where fixed interiors are being dealt with, and where in many instances an operator can walk from place to place giving a flash at will, taking care, of course, to keep out of the line of lights of the lens.

In groups and cases where as nearly as possible a simultaneous flashing of more lamp than one is desired, success will depend in a great measure upon the form of lamps employed and the method adopted for firing them. Some very ingenious contrivances have been invented for this purpose; but it is doubtful if they all fulfil what is claimed for them.

There is, however, but little difficulty in firing any number of lamps in reason at one and the same moment of time, provided they are of the pattern I recommended in a previous article, and suitable means used for projecting the magnesium into the flame at the same time.

I can remember a case in theatrical working where a full stage was being photographed by means of the flashlight and where this difficulty was experienced, and no end of bother was met with. In all cases where there is a free passage for the pure magnesium powder to reach the flame by blowing, the fault generally lays in the lamps being placed at non-equal distances from the source of pressure on the rubber tubes, and in some instances an insufficiency of power to project the powder into the flame on account of the distances the same was from each other.

Whenever the forms of lamps used are those recommended by the writer in a previous article, there is no difficulty at all in overcoming this when the pressure is supplied from a well-charged cylinder of oxygen gas. By using compressed gas the utmost amount of pressure is easily obtained, care being observed that the coupling tubes to each lamp are not only securely fastened, but that all the lamps have independent tubes of their own leading right up the branch piece at the cylinder nozzle. In the case of two lamps a Y piece is sufficient, but this branch must be possessed of as many ways as there are lamps to fire, and each tube must be of the same length. When these arrangements are carefully attended to, there will be no hitch or trouble in firing several lamps at the same moment of time.

For applying the pressure to the tubes a fine adjustment valve, screwed on to the nozzle of the cylinder, will be found to be the easiest method of suddenly applying the pressure. With a well-appointed set of apparatus of this kind, stage work is successfully performed. The main factor is to make certain that there is no moisture in or about the tubes, and that they are absolutely clear in their passage ways.

Two tube lamps, each containing ten burners, will be ample for any stage, one being placed at the wings on each side, of course as much of the ordinary light used being employed at the same time; this is of more importance than many imagine, and, where light fixtures and dresses are concerned, will tend to the yielding to half-tones in the negatives. With the form of lamp suggested there is no limit to the amount of magnesium that may be placed in the cups, and pure magnesium only should be used.

T. N. ARMSTRONG.

## A SIMPLE ACETYLENE GENERATOR.

For some time enlarging was to me an irksome and unsatisfactory operation, in consequence of illuminating difficulties. I had used magnesium ribbon with but little success, the lighting being uneven and producing patchy prints. Although I kept the burning ribbon in constant motion, and used a ground-glass screen (this latter prolonging the exposure immensely), I abandoned magnesium as a satisfactory light and tried daylight. Daylight was good, but variable, and, of course, with limited time at one's disposal, not always convenient. I therefore gave up the idea of making enlargements from the comparatively few negatives I prized, until recently the merits of acetylene gas as a powerful actinic light came to my notice. Still doubtful, I decided to again try and obtain some satisfactory enlargements.

Accordingly, I looked up the subject of acetylene lamps, and came to the conclusion that, amidst many forms of generator, one only would suit my requirements, and that one was fortunately of quite simple principle, and which I have been able to adapt to my needs, and enlarging now offers me little difficulty.

Acetylene gas is formed by the action of water on a substance (calcium carbide), a comparatively new commercial compound of carbon and the metal calcium (the metal of lime) produced by direct union of lime and carbon in the very high temperature of an electric furnace.

## THE APPARATUS IS AS FOLLOWS:—

A is a cylinder of sheet zinc, into the side of which, close to the bottom, is soldered a lead pipe, E.

B is a smaller cylinder of zinc, inverted, from the roof of which is

suspended, by means of a hook, H, in the roof, a perforated zinc cage, C. B is lifted out, and A almost filled with water.

Having taken out the zinc cage and in it placed a quantity of calcium carbide—half a pound to a pound—it is put in place, and the cylinder, B, with its cage, lowered in the water. The tap at K is turned on, and the cylinder slowly sinks. When the cage has almost reached the water the tap is turned off, and the connexion to the gas jets, to be presently described, made, and the tap turned on; the cylinder sinks further, when the cage, with its load of carbide, will come in contact with the water, and acetylene commences to come off. The tap is still allowed to be open, and the mixture, now of air and acetylene, is passed through the jets for a minute or so before the jets are lighted. The apparatus is now ready, and will continue to supply acetylene automatically until the calcium carbide is exhausted.

The details of construction of the generator I will now explain. Having procured sheet zinc, say a piece 4 ft. x 3 ft., which will be enough for a generator having cylinder, A, about 1 ft. in diameter and 1 ft. 6 ins. high, cut a piece 1 ft. 6 ins. x 3 ft. and bend about  $\frac{1}{2}$  in. of the shorter edge, up one end and down the other, so that the two will hook into one another when curled round and thus form a tube. Flatten down the joint so formed with a mallet, against a piece of wood held inside. Clean the joint with killed acid, i.e., muriatic (hydrochloric) acid neutralised by adding zinc scraps until the effervescing ceases, and solder the joint, which, if carefully done, will be quite strong. Now cut a piece of zinc  $\frac{1}{2}$  in. to  $\frac{3}{4}$  in. larger than the circle of the tube. Hold this on the tube and beat down the edge of the circular piece of metal to turn up close to the tube all round. This is somewhat difficult at first, and it is perhaps

advisable to fix the bottom on temporarily by a drop or two of solder, of course after cleaning with killed acid to ensure the solder holding. The edge being beaten up close all round, the joint is cleaned and soldered. A piece of composition gas pipe,  $\frac{3}{8}$  or  $\frac{1}{2}$  in. size and 4 ft. long, is bent in a circle 9 ins. in diameter, with a short end of some 3 ins. to go through the side of cylinder, A, and projecting in the plane of the circle, and the long end standing up at right angles to the plane of the circular part. A hole is now punched in the side of the cylinder, one inch from the bottom and just large enough to admit the pipe. The metal around the hole is cleaned and the short end of the pipe is scraped clean, inserted so as to project about two inches, and soldered in place. I found it an advantage while soldering the pipe in the hole to support the remainder of the pipe by means of cloths placed inside the cylinder, A, which was itself supported firmly in a horizontal position. On the end of the composition pipe at K a gas tap, with nozzle for india-rubber tubing, is soldered. The cylinder, A, is now complete.

Cylinder, B.—A piece of zinc 1 ft. 6 ins. x 2 ft. 6 ins. is now taken, and the shorter edges bent, joint soldered, and top put on, as in the case of cylinder, A, except that, before the zinc plate to form the top is fixed, a hook of galvanised iron wire is soldered to the centre of the plate on that surface which is to be inside. The hook may easily be made of a piece of moderately stout wire, bent in a circle, with a hook bent up at right angles to the plane of the circle. The top is put in place, the edge beaten down and joint soldered, and the hook will now be in the position for hanging the cage from; and cylinder, B, is complete.

The cage, C.—A piece of perforated zinc,  $12\frac{1}{2}$  ins. long and 4 ins. deep, is bent to form the sides of a sort of box of 3 ins. side. The joint soldered, a piece of perforated zinc,  $3\frac{1}{2} \times 3\frac{1}{2}$  ins. is now cut,  $\frac{1}{2}$  in. of each edge turned up and fitted to the sides and joint soldered, thus making a cage  $3 \times 4$  ins., with open top. Two pieces of moderately stout wire in the form of hooks are now soldered to opposite sides near the top of cage, another piece of wire about 5 ins. long, with loop made at each end to engage with the hooks, and bent to an angle to form a means of swinging the cage from the hook in the roof of cylinder, B.

For the purpose of lifting for charging, a wire handle may be soldered to the top of B; a considerable convenience, but not absolutely necessary.

The apparatus is now complete for the making of acetylene, when cylinder, A, is filled with water and cage, C, with carbide.

A coat or two of good enamel will improve the look of the generator.

With regard to the remaining portion of the lighting apparatus, that, of course, depends to a large extent on individual requirements. For my own purpose of enlarging from half-plate to  $12 \times 10$  ins., I found three Bray's burners, of size 00000, give a good light, and yield evenly exposed prints with an exposure, though a normally dense negative of one minute. The three burners are arranged in line about 3 ins. apart. The burners may be screwed into a piece of lead pipe about 1 ft. long, one end of the pipe being either soldered up, or simply beaten flat and bent over and beaten again. The pipe is fixed to a substantial block of wood by bent nails. This rather primitive arrangement can be improved, and in the event of requiring the light for a much longer period than that mentioned—one minute—the lead pipe should be replaced by a piece of  $\frac{1}{2}$ -in. diameter brass pipe, drilled in its length with taper holes, to receive the burners. It is evident any number of burners can be used if a sufficient length of brass tube is available, but for enlarging I have found three ample. For taking portraits, eight to twelve burners may be arranged at a height of about 7 or 8 ft., placed at the side of the sitter. On the opposite side to the light a white screen (a sheet answers excellently) must be so placed as to soften the shadows by reflected light. The conditions of exposure I have found are (a) light (eight burners), five feet from sitter; (b) on opposite side white reflector, close to sitter; (c) ordinary plates; the necessary exposure was four seconds. The negative was excellent; the high lights being clean, yet soft, and the shadows well illuminated, it compared very well with an ordinary sunlight photo.

A. E. T.

## THE FUTURE OF ACETYLENE.

The production and use of acetylene has now passed the purely experimental stage, says Prof. Vivian Lewes, and the only question as to its future is whether its use is to remain as a luxury or to expand into an important factor in modern civilisation. Should it be found impossible to lower the price of the calcium carbide, from which this brilliant illuminant is derived, by the simple process of bringing it in contact with water, then the field of utility enjoyed by the gas will be restricted to those districts where coal gas is unknown, and where it becomes invaluable as an illuminant for country houses. It will also undoubtedly play an important part in the railway lighting of the near future, as twenty per cent. of it added to oil gas doubles the illuminating value and enables the gas cylinders to run for double the time at less than double the cost. If, however, improvements in the method of manufacture or other causes lead to the cheapening of the calcium carbide, an unbounded future is opened this interesting hydro-carbon.

Already in America cheap power has enabled carbide to find its way into the gasworks, and acetylene is beginning to be used as an enricher of coal gas—a function which it is specially fitted to perform, as its freedom

from condensation during cold weather gives a permanency to the illuminary power of the enriched gas which cannot be obtained by any other means.

The only fear with acetylene is the attempts made to develop its use in directions for which it is not fitted. For instance, there is no one who knows anything of the subject who does not look with grave distrust on the acetylene bicycle lamps that are being placed on the market. In the first place, if the lamp behaves itself, the light given is far too strong, and tends to startle horses and blind pedestrians; whilst, in the event of a spill, the flare caused by the sudden shake up, and probable overflowing of water into the carbide, taken in conjunction with a muslin dress, supply the factors for a tragedy that one shudders to contemplate.

Given a good generator, not automatic, but with a holder capable of containing the whole of the gas generated by the charge of carbide, good burners, and proper fittings, acetylene is an ideal light.

The contamination of the atmosphere is, light for light, less than with any other illuminating flame. Plants are not injured by it, and colours stand out in their true tints, whilst the problem of finding a suitable burner, which has been one of the greatest troubles in utilising the gas, has now practically disappeared.

#### NEWMAN & GUARDIA'S LIMELIGHT JET.

FIG. 1 is a side elevation of a limelight apparatus of ordinary construction, but with the invention applied thereto; fig. 2 is a plan of same; and fig. 3 is a longitudinal section of the part of the apparatus comprising the invention.

Messrs. Newman & Guardia say: For the purpose of our invention we employ a burner, A, mounted at one end of a tube, A<sup>1</sup>, and directed in the usual way so that the jet of combined gases issuing from it impinges against the piece of refractory material, c, in the manner well known in connexion with this kind of light-producing apparatus. The end of the

annular space, g, between the two tubes, B and D, except at the front end. Combustible gas, such as coal gas or hydrogen, for example, is admitted through the branch, N<sup>1</sup>, into the annular space, g, between the inner and outer tubes, and oxygen under pressure into the inner tube, D. The jet of oxygen issuing from the nozzle, E, at the end of the inner tube, D, enters the trumpet-mouthed end of the tube, A<sup>1</sup>, connected with the burner, A, and draws with it, somewhat after the manner of an injector, a current of the coal gas or hydrogen from the annular space, g<sup>1</sup>. The oxygen and coal gas or hydrogen mix together in the tube, A<sup>1</sup> (which is the only mixing chamber we employ), and pass on to the burner, A, where they burn in the usual way, the flame impinging upon the refractory material, c, heating the latter to a white heat and thereby producing an intensely bright light as usual. By these means, as a mixture of gases only takes place in the comparatively small tube, A<sup>1</sup> (which is preferably of about the same cross section throughout its length and without contractions at any part), and not in a comparatively large mixing chamber with a contracted inlet and outlet as heretofore, the quantity of mixed, and therefore explosive, gas present at any given moment is extremely small, and the danger due to explosion is consequently reduced to a minimum.

In order to minimise, as far as possible, the effects of the small explosions which are possible even with our improvements, we employ a safety valve, N, in connexion with the annular space, g, between the inner and outer tubes, D and B, so that, when a trifling explosion occurs in the tube, A<sup>1</sup>, or in the front part of the annular space, g, the safety valve, N, opens and the pressure is relieved. The safety valve, N, also serves the purposes of preventing such a rise of pressure in the annular space, g, by the access of oxygen thereto, as would permit of the oxygen travelling back into the pipe supplying the coal gas or hydrogen.

#### WEISS'S APPARATUS FOR DIFFUSING THE LIGHT IN PHOTOGRAPHING BY ARTIFICIAL LIGHT.

The apparatus consists of a curtain, 1, made of transparent material, which possesses the faculty of spreading the rays of light. For this purpose tracing cloth has been found suitable. The curtain is fixed to a shaft or axis, 2, so as to be rolled up or

down, the shaft being rotably seated in the arms, 3, 4, of a bearing rod, 5, and carrying on one end a cord, 6, for rolling up the curtain. The bearing rod, 5, is fixed to a vertical rod, 7, which, with a sleeve or socket, 9, fixed to a tripod, 8, forms a stand.

By means of this arrangement the curtain, 1, can be adjusted to any desired height.

#### WARM TONES ON WET-COLLODION SLIDES.

"COLONIAL" has not read me correctly; it is a long time (some years, I think) since I wrote an article on wet-collodion work. The reference to it which I permitted myself on December 2 was purely reminiscent; at the same time, the query put can, I think, be answered without much

\* See THE BRITISH JOURNAL OF PHOTOGRAPHY, December 23, 1898.

tube, A<sup>1</sup>, opposite to that from which the jet of combined gases issues, is trumpet-mouthed, as shown in fig. 3, and is connected with the front end of a tube, B, which contains within it a third tube, D, the front end of which is provided with a nozzle, E, directed towards, and preferably entering, the trumpet mouth of the tube, A<sup>1</sup>. The rear end of the inner tube, D, passes through a stuffing box, F, in the rear end of the outer tube, B, or is otherwise so adapted that no gas can escape from the

difficulty. Warm tones are to be had more particularly with mercury re-development or intensification. Premising that sepia is a colour as to the exact shade of which a great variance of opinion seems to exist, e.g., I have had sepia carbon tissue which is not at all what my preconceived idea of sepia led me to expect, and I don't know two people who agree as to the exact colour or tone: but let us take it to be a dark reddish-brown, and, if my memory is not at fault, you will get more or less approaching the shade with combinations of the following chemicals: Gold chloride, mercury chloride, uranium nitrate, potass ferridcyanide. Take the usual uranium intensifier, and add to it a few drops of mercury chloride solution. A simple formula is:—

Ferridcyanide of potass .....	2 grains.
Uranium nitrate .....	2 "
Chloride of gold .....	$\frac{1}{10}$ grain.
Water .....	1 ounce.

But the tone is not so warm as with mercury chloride. Of course, "Colonial" has tried the usual toning solutions and the old sel-d'or combined toning and fixing bath?

Now, there must be some body and vigour in the slide, or no large amount of colour will be got out of it. *Exposure also, developer, and extent of development* have to be considered. Some interesting articles on this subject are to be found in *THE BRITISH JOURNAL OF PHOTOGRAPHY* of earlier years—1888, 1882, and 1881—not to go further back; and, upon this very point of warm colours in wet-plate slides, I may quote *THE BRITISH JOURNAL OF PHOTOGRAPHY* for January 21, 1881, p. 26: "The colour of a toned transparency depends to a great extent upon the character and colour of it before toning, for, if it be too cold in the first instance, none of the usual toning agents will render it warmer, unless, indeed, we have recourse to mercury" (my italics). "If warm tones are sought for, the development of the picture must be so modified that it comes out of a brown or reddish-brown colour. To secure this colour, the bath should be in the best working condition, and the collodion as newly iodised as will yield clear lights. A full exposure must be given, and the picture brought out with pyrogallie acid, restrained with acetic acid only. A liberal quantity of solution should be used to dilute the free silver on the plate, so that the detail is well rendered before much density is obtained. With a picture of this character almost any tone, &c., may be obtained by after-treatment with gold, platinum, or palladium. The colour may be considerably modified by the use of citric or tartaric acids as a restrainer in place of acetic, while, by the admixture of both, a great variety of tints may be secured without after-toning."

The silver bath which I invariably used was the following:—

Recryst. nitrate of silver .....	1 ounce.
Nitrate of baryta .....	40 grains.
Iodide of potassium .....	1 grain.
Distilled water .....	12 ounces.
Glacial acetic acid .....	2 minims.

Enough for two or three baths was made and kept "sunned" as far as possible when not in use; the developer was usually "iron":—

Iron sulphate .....	150 grains.
Methylated spirit .....	$\frac{1}{2}$ ounce.
Glacial acetic acid .....	$\frac{1}{2}$ "
Water .....	10 ounces.
Brown sugar .....	$\frac{1}{2}$ ounce.

Made up in quantity and kept as long as possible before use. The collodion was generally an old sample, or, if new, tinted with iodine tincture. Occasionally a drop of pure nitric acid would be added to the silver bath.

A great deal more could be said, but I think the above will put "Colonial" on the right road.

J. PIKE.

### "BY COOT AND HERN."

THE tangible possession of a camera is a powerful incentive to strike out for new scenes far remote from the beaten track; and I opine that, if the sun, "snapper up of unconsidered trifles" (I do beg he of Avon's pardon), has accomplished this, the camera has not existed vainly.

Last year, for a brief break in the monotony of every-day life, I got away to sunny Belgium, to explore the merry Meuse, which ambles along so peacefully through a veritable fairyland of Flora.

Equipped with a Kodak and a supply of spools, my impedimenta weighed but a few pounds, and even Monsieur le Douanier smiled harmlessly at my little instrument and tapped it playfully as he passed my baggage at Antwerp.

The best route to the merry Meuse is undoubtedly by the Great Eastern Railway *via* Harwich and Antwerp; passengers leaving town on Saturday night arrive at Brussels in time for service at the Cathedral on Sunday. Thence the journey may be continued to Namur, where the night should be spent. Here we are on historic ground; one calls up memories of Uncle Toby, and smiles at the literary eccentricities of his creator; from the fortress there is a fine panoramic view which, thanks to a particular bluish of M'sieu Sol, we are permitted to carry off; in the

by-streets there is much worth photographing; and then we get down to the landing-stage, and book by boat to Dinant.

Surely this is a picturesque pilgrimage; it matters little which way one looks; foliage and fern, castle and crag, prettiness and purity, peep out at every corner. One can use all his spools long ere Dinant is touched, but that we have other pictures ahead.

At Dave, Godinne, Profondeville, there is ample to repay the peregrinating pilgrim; the Bois de Dave is alone worth the visit twice over.

Once at Dinant, we have no end of excursions before us; this merry Meuse is enchantingly lovely, and it would be futile to guess how long one would be inclined to stay there; but our hours of idleness come to an end, and we hark back to the conventionalities of life, impressed that there are many more happy days in store for our camera and ourselves when the opportunity occurs. I do pray that it be soon, for this ramble "by coot and hern" has positively spoiled me!

WILFORD F. FIELD.

### STEREOSCOPIC EFFECT ON THE SCREEN—MR. ANDERTON'S SYSTEM.

My present invention, says Mr. Anderton, has for its object certain improvements upon the method or system by means of which pictures projected upon a screen from an optical or magic lantern or lanterns are seen in relief or with stereoscopic effect, forming subject-matter contained in my former specification of patent bearing date July 7, 1891, and numbered 11,520, to which reference may be had and in which it is stated in dealing with the subject that preferably a number of glass plates placed at the requisite angle for producing polarisation by refraction, enclosed in a convenient case or frame, will be used.

These plates are so arranged in each lantern that the light from one will emerge polarised in a plane at right angles to that emerging from the other. That the images of the two stereoscopic slides or pictures, each polarised in a plane at a right angle to the other, are projected and superposed on a screen of ground glass, metal, or any other substance or material that will not depolarise or elliptically or circularly polarise the images it receives. Preferably a calico screen covered with dead silver paper is used. It will be understood that the scientific arrangement of the apparatus, as to the fitting up of same, is governed in the present case by the scientific principles described in my 1891 Specification, No. 11,520. The thin glass plates are placed in a suitable case or frame contained within a lantern having an objective lens. The drawing herein-after more particularly referred to clearly illustrates the arrangement. Now, the dead silver paper referred to in connexion with the calico screen, although serving the purpose of reflecting the polarised light as received, possesses certain defects, namely, the squares of silver leaf composing it are visible and tend to mar the effect of the pictures projected upon it.

Further, the nature of its reflecting surface is such as to cause a deficiency of lateral reflection, and consequently the stereoscopic pictures projected upon it cannot be seen with proper effect excepting when the observer or observers are stationed within a certain limited space directly in front of the screen. In other positions the pictures would appear darker than when seen from a front position and also uneven in illumination, the side farthest from the observer appearing darker than the side nearest to him.

It is to obviate these defects that my present improvements apply. I cover the silver surface of the screen with perpendicular lines or striations, the angle at which a bright and effective view of the stereoscopic pictures may be seen being largely extended, and the solidity and

general effect of the pictures is also greatly improved by this means when seen from a position directly in front of the screen.

An important point in my present improvements is the use of polarisers and analysers in conjunction with a lined or striated metallic screen, with the object of obtaining stereoscopic effects from pictures projected upon such screen.

A further improvement upon my said prior patent of 1891 consists in provision being made for the protection of the thin glass plates of which the polarisers and analysers may be composed from the action of the atmosphere, and, consequently, moisture becoming gradually condensed upon the inner surfaces, thereby rendering them dim and practically useless. And my said improvements in this respect consist in covering the edges of the said thin plates with cement, that will not itself decompose, and

will also sufficiently exclude the air, and, again, by cementing the plates within a metallic frame, mount, or case, as a further protection from deterioration, from condensation of moisture, or from other cause or causes.

Furthermore, the thin glass plates were previously in my former specification arranged at slightly varying angles to each other in order to distribute the multiple reflection from the inner surfaces; this was effected by inserting thin strips of metal or other material between the glass plates, but at one end only. An improvement upon this method consists in alternating the strips of metal or other material for tilting the glass plates. I will here draw attention to the diagram annexed, in which *a* represents the lens or objective of the tube, *b*, of the lantern, *c*; *c*<sup>1</sup> is the mount or case into which the thin glass plates, *d*, are cemented; *e* represents strips of metal or other material placed alternately at the top and bottom in order to give the thin glass plates, *d*, different angles in the same plane for the purpose of producing the effect already referred to.

As seen from *A*. For example, a strip, *e*, of metal or other material is placed between the glass plates, 1 and 2, *d*, on the right hand in the case, *c*<sup>1</sup>, then a strip of metal, *e*, or other material is placed between the glass plates, 2 and 3, *d*, on the left hand in the case, *c*, and again between plates, 3 and 4, *d*, on the right hand, and so on until the bundle of plates is completed.

By arranging the plates as described and shown a well-defined image is obtained. I may sometimes deem it advisable to somewhat modify the details and arrangement above set forth without, however, departing from the essential features of my invention.

#### ENLARGING.

At a meeting of the Leeds Camera Club, held on Wednesday evening, December 28, "Enlarging" was the subject dealt with by Mr. John H. Gash, who said no doubt there were many who at times felt they would like to see a favourite negative in a larger size, but were deterred by the impression that enlargement was a difficult matter and required costly apparatus. That idea was entirely wrong, for any one having a camera could, by using daylight and a little trouble, produce an enlargement to the size they desired and at little or no extra cost. Choosing, then, a window facing north for preference, place outside a board, previously covered with white paper or cotton, at an angle of 45°; this will reflect the direct light from the sky through the window. The camera should now be placed on a table, with its focussing screen as close as possible to the window, and in front of the board already in position outside. With a curtain, or a piece of American cloth, block out all light coming through the window except that passing through the camera, moving now the focussing screen from the camera; place the negative in its place, having its film side to the lens. Another board is now required on which to pin the bromide paper, and this board must be placed vertically and quite square with the camera. Its position or distance from the camera is determined by what size the enlargement is to be; say, if it is desired to enlarge from quarter-plate to 12 x 10, that will be about three diameters. Multiply the focal length of the lens by 3 and add the focal length, and the result is the distance from the lens to the board. Divide this by 3, and the result is the distance from the lens to the negative. For example, if using a lens with eight-inch focus, then 8 by 3 are 24, and 24 and 8 are 32, then 32 inches is the distance of paper from lens, and 32 divided by 3—nearly 11 inches—is the distance of lens from negative. It is, therefore, quite evident that 32 and 11+43 inches is what the board will be from window. The image will be visible on the paper, and only requires putting in exact focus by means of the camera screw, and your image is the required size. Do not stop down the lens more than is required to bring all parts into focus, use slow brand of paper, and take three or four trial strips, taking in both the highest lights and deepest shadows, starting with about ten seconds' exposure at *f*-16. When satisfied you are correct, pin on your 12 x 10 sheet of paper, expose, and develop.

Mr. Gash then dealt with artificial light, and in this case, using oil lamp, ordinary gas, or incandescent gas, a condenser is necessary, and it must cover the negative or that portion of it that is wanted. Expensive enlarging lanterns, whilst convenient, are quite unnecessary, for now we can curtain the doorway, placing the camera, with its lamp and condenser, outside, and allowing only the lens to project through a hole in the curtain. The board is again placed in its proper position, its distance determined as before, care being exercised to see that it is vertical. It should be moved until the image is in proper position and truly focussed. At this point a most important fact must be noticed. Take out the negative, and see if the disc of light is equal, and if any dark shadows appear. Remove the lamp nearer to or farther from the condenser until all parts of the disc are equally bright. The negative can then be replaced, the curtain put back, and all light except that coming through the lens stopped out. Then put on the lens cap, pin up paper, and expose again, making several trial strips until correct exposure is obtained. The question of the paper is largely a matter of opinion; but, whatever brand is used, use the developers recommended with it by its makers, and either the metal or the oxalate and iron will give equally good results, though, for a beginner, Mr. Gash thought the metal was the best, as this could be diluted with water to produce softer results if desired.

#### A CONVENIENT ARRANGEMENT FOR COPYING.

To the table of an old camera stand is fixed a long open-work frame with slightly raised edges, which, when out of use, is dropped as in fig. 1, taking up little room.

When required for use, the longer end is supported on anything firm.

An upright board, to which a flange is screwed (fig. 3), is fixed with a clamp, as shown in fig. 2, and the camera is placed on a board, which slides easily between the raised edges of the frame. By this means the

camera and object to be copied are easily kept parallel, and the distance between them is readily adjusted.

The upright board is covered with black velvet, and the opening in the upper end of the frame is filled in with a dark material, rendering it more easy to see to focus.

#### BUTTERWICK'S HAND CAMERA.

"Yes," said Butterwick, "I did make that hand camera myself. People may sneer at it—I suppose Jones has been telling you about it—but when I set out to construct it I was determined to produce an instrument which should be original in conception and design. I have succeeded beyond my wildest expectations.

"Of course, firms who make a speciality of hand cameras may be jealous, but I am glad to say that every house to whom I have exhibited it has had the honesty to declare that they have nothing like it on their lists. A distinguished authority on hand-camera mechanics was looking at it only yesterday. His words were: 'Seriously, Butterwick, good is not the word for it.'

"Of course, people will make remarks. When you say that it is

'hardly an advantage to have the sheaths and plates with all that amount of play, you only show me how utterly unable you are to grasp the scientific principles which underlie the construction of the camera. I made those sheaths rather too large for the plates and rather too small for the camera on purpose. It's the only way to get rid of rattle. Look here! You take the camera out, and you certainly do get a little rattle for a minute or two. What becomes of the motion of the plates and sheaths? It's converted into heat. Don't you know that heat is a mode of motion? The rest is simple. The heat, of course, expands plates and sheaths, and wedges the whole tightly and automatically into a coherent mass. It's the simplest possible application of molecular dynamics.

"Then, you don't mean to say you can't see why the shutter is arranged to go off vigorously? You surprise me! A short, sharp shock is hardly an ideal factor in a hand-camera release, you say? My dear sir, kindly look at the matter in an unbiased frame of mind. Are you or are you not acquainted with the value of horizontal and vertical lines from a pictorial point of view? Do you or do you not know that a celebrated photographer uses a slit instead of a lens, vertical or horizontal, according as he wishes to emphasise those particular lines in his composition? My release does this while at the same time fully exposing the plate in a fraction of a second. I should have thought that the most unenlightened mind would have perceived that, by giving a slight displacement to the side of the camera at the moment of exposure, the vertical lines are broadened in a manner which pleases the eye and appeals to the finer sensibilities of the mind, whilst an upward displacement (instead of a lateral) does the same for the horizontal lines. Of course, sir, I don't expect that the man who is content with the 'usual thing' will appreciate the advantages of my hand camera.

"So Jones has been telling you he don't care for the idea of the shutter occasionally cutting off half the picture from the plate! He said the same thing to me. It only convinced me that Jones is singularly unacquainted with present-day utterances on pictorial photography. You take up a photographic paper, and you'll find the editor talking like this: 'How often must we allude to that commonest of defects in the prints which our readers submit to us for criticism, viz., the inclusion of too much subject? Had an inch been trimmed off the right-hand side of your print, its pictorial quality would have been immeasurably enhanced.' That's just what my hand camera does—removes superfluous subject.

"No, I haven't patented it. Do you suppose that, after devoting so much of my valuable time to constructing an instrument that will bring credit and renown to the photographic art, I shall offer any obstruction to its use by every photographer in the land? I am content, sir, to let a fabulous fortune go by, and to bequeath my camera to the photographic world and its heirs for ever. 'Palmam qui meruit ferat.'"

VANDYKE.

### HOW I HOLD MY CAMERA.

In the course of a few seasons' experience with hand-camera work, when taking photographs during the holidays and on occasions of festivals, prize-givings, or processions, I have found it impossible to secure a point of vantage that enabled me to avoid having very large heads or figures in the foreground of the picture if I held the camera in the orthodox manner. I therefore obtained an idea of the composition of the picture by looking into the finder, and the moment before the exposure, lifted the camera so that the back of it rested against my forehead. Looking along the lower edge to level the camera, I waited for the interesting portion of the ceremony, and then touched the release of the instantaneous shutter. Unless one is very tall, this method of avoiding too much foreground is very satisfactory—at least, I have found it so—and there is less likelihood of shaking the camera than if held against the side of body or on the chest. On one occasion, in Ireland, at a distribution of prizes by Lord Roberts, the only elevated position I could get was on an ordinary chair, and then the busbies and caps of the soldiers interfered with my view; so, taking a guinea pocket Kodak, I held it above my head as far as I could stretch my arms, and, when fairly level, made the exposure. The result was so good that, notwithstanding there were at least 200 people in the group, the principal personages could easily be recognised, and, when enlarged to half-plate size, were quite sharp and the portraits remarkably clear. On more recent occasions I have used the pocket folding Kodak in the way described, by resting against my forehead, and at the last Lord Mayor's Show exposed a dozen quarter-plates in a Holiday hand camera.

I don't mean to say that on all occasions it is the best way to hold the camera, but I do think on many occasions it is; and if a concave glass or square section finder is fitted to the bottom portion, so as to just include the amount that will be shown on the plate, it leaves little to be desired.

I have seen it advocated to hold the camera under the chin, but never against the forehead, and, as in country work one often wears a soft cap, it will rest against that as well as against the forehead; but even with a hard hat it is simple to push it on the back of the head for the time being. Perhaps some of your readers may find the method worth trying.

G. R. BAKER.

### THE "CHROMO-GRAPHOSCOPE."

THE direct photography in colours—that is, the reproduction of objects in their natural colours without employing anything else than the sensitive plate—is not yet generally practised, notwithstanding the splendid experiments of Professor Lippmann; on the contrary, the indirect method is now employed in most photo-engraving establishments. As is known, says M. G. Veuille in *The American Annual of Photography*, the process permits of the reproduction of the photographed object in as many proofs as desired, by means of the three fundamental colours whose reactions are originated by the light itself.

By this method, devised a long time ago by Messrs. Cros and Ducois du Hauron, one must first make three negatives under certain conditions and through properly coloured screens, then print the diapositives in colour, which, by their superposition, give the sensation of the colours of the object. This double and delicate operation is extremely simplified by the use of the chromo-graphoscope of Ducois du Hauron. With this apparatus—which the firm of H. Mackenstien, of Paris, has constructed under the guidance of the inventor—the negatives and the adjustment of the plates used are made in an automatic manner, so to say.

With the chromo-graphoscope M. Ducois du Hauron makes three monochromatic images, one by the side of the other, on the same sensitive plate, the position being regulated beforehand, screens—violet, green, red—correctly adjusted, act as the ray filter for each negative. To avoid the image appearing reversed, the apparatus is provided with a prism, and the chromo-graphoscope must therefore be placed vertically, the lens turned towards the zenith.

When the negatives are obtained one by the side of the other, one can utilise them immediately for the operations actually in use for printing in three colours; but, if one prefers to use the apparatus itself to obtain the coloured representation of the objects photographed, this can also be done, all that is necessary is to make a diapositive of the triple original on a plate glass, and this proof being placed where the negative was before will give, by means of the coloured screens and the mirrors of the chromo-graphoscope, the synthesis of the colours and the desired effect. In this case the lens is replaced by a kind of ocular, that is to say, a magnifying lens.

To speak of a colour-blind artist sounds like joking, said a noted London oculist; but, strange as it seems, there are several persons so affected who can, nevertheless, paint extremely well. Numbers of colour-blind people there are, of course, who draw perfectly in pencil, ink, and crayons, but I myself know a scene-painter attached to a provincial theatre who, though "colour-blind," paints all its scenery, and has quite a local name, not only for his "interiors" and oak chambers, but even for landscapes. I can tell you also of two London ladies who consulted me for colour-blindness who paint really beautiful pictures. One is the daughter of a late famous artist, and was taught painting by her father. She is quite unable to distinguish red from green, but her colours are labelled with the names, and she has been taught which to use for certain effects. Possibly her painting may seem to her eyes, as it were, drawing with a brush and "shading" with the colours. The other is a lady artist of some celebrity, who has for years exhibited annually in London. The public are not aware that she is colour-blind. She painted the *Wedding Group* for a certain noble bridegroom a year or two ago, and also several public men's portraits, and one of an eminent physician fetched 500 guineas. There is a gentleman residing at Kensington who, having years ago left the Navy through finding his advancement hopelessly barred by his colour-blindness, is at present making several hundreds a year by his brush as an artist, designing most artistic and brightly coloured picture "posters" for advertisement boards.

THE BALLOON AS AN OBSERVATORY.—The balloon has now been recognised as an indispensable observatory, says the Rev. John M. Bacon, in the *Contemporary Review*. In some ways it affords the student of astronomy and optics opportunities which cannot be gained in any station on earth. The extraordinary brilliance and steadiness of celestial objects viewed by optical aid from a balloon 10,000 feet or 12,000 feet above sea level must be seen to be realised. Indeed, from half that height, the full moon, regarded through an ordinary field glass, becomes an object intolerable to gaze upon; but the case is far otherwise on mountain observatories, which cannot be wholly free from disturbing currents or from that peculiar stratum of air always and everywhere clinging to earth. It is obvious, then, how many questions can be dealt with to great advantage from higher and purer regions. Most important data are being gathered bearing on refraction as influenced by altitude, by temperature, and humidity. Spectroscopic observations taken from the earth, and again a few minutes later from some thousands of feet above, are destined to throw very valuable light on those lines which have simply a telluric origin. It is even reasonable, indeed, to hope that the corona may be photographed without eclipse. Again, many doubtful observations needing low powers, and hitherto made from earth, will receive a crucial test when repeated from above, and rare phenomena, such as a total solar eclipse or shower of meteors, too often hid from the observer below can hardly escape the view of the voyager above the clouds.

## LANTERN MEMS.

It is often the unexpected that happens, and, if a catalogue could be kept of difficulties experienced and *contretemps* in connexion with lantern entertainments, it would be a bulky volume. There are few lanternists but have had their little or great difficulties, and fortunate is the lecturer who has not experienced a trial, even if he has not been put in a dilemma. Slides put in the wrong place or upside down, a reference to the on-coming slide which was totally opposite to what appeared, unexpected failure of the light, either through faulty lamp or jet, indifferent manipulation, or the gas going out.

PERHAPS one of the most ridiculous and awkward experiences of this sort took place at a chapel some little time before Christmas. It was decided to give the young folks a treat, and what more suitable than a lantern entertainment? The question of subjects to be chosen was a vexed one, and, as some of the organizing body thought, as it was to take place in the chapel, nothing frivolous must be chosen, the, to most minds, suitable subject of the "Pied Piper of Hamelin," which was suggested, should follow a "Tour in Switzerland," was tabooed, and the "Life of Moses" substituted. All went well until the end of the series of the latter, when the operator, perhaps thinking the pent-up feelings of the young folks wanted a safety valve, put in the lantern the comic slipping slide of "Man beating boy." The effect was wonderful, for a roar of laughter followed that would have delighted the heart of a Sir Wilfrid or any one who can give or appreciate a joke.

MOST lanternists know this slide, and when it is remarked that the boy is laid across the man's knee, and is receiving a whipping from a cane, one can realise how ridiculous the incident was, and the annoyance of the deacons and others connected can be better imagined than described. However, after the affair was over, and the matter was discussed, it was suggested that the operator should not be blamed too much, for, with a little stretch of the imagination, it might be found to work in. "How's that?" said some one, "Because it was evidently meant for Moses striking the rock! Ah! ah!"

THE more one uses the electric arc light in lantern work the more interesting it becomes, and, provided a suitable current is available,

also good carbons and a well-constructed lamp, the light can fairly be said to be an ideal one, for it is not only extremely easy to regulate, is clean in manipulation, but gives intense light and magnificent definition. As regards the latter, lenses of quite average quality, and single achromatics of good make and long focus give projections of such excellent sharpness that they are nearly equal to the most expensive combination. If an ammeter is at hand, and can be connected in the electric circuit, it is most interesting to watch the fluctuations of the hand as the "arc is struck," also as the light settles down, and, finally, as the carbons burn away and the arc lengthens in consequence. The higher the ampère, the greater the light, and, if the carbons are fed regularly, the maximum light with steadiness is maintained.

REFERRING to a few notes made the other day when testing a new form of variable resistance, it was found that the difference in the position of the carbons made an enormous difference in the ampères of current employed, and consequently in the intensity of the light, it being as much as eighteen ampères when properly adjusted and working steadily, with the upper carbon at the best position behind the lower to give best results, and several ampères less when separated too much or with the carbons not suitably set. If the connexion were improperly made and the negative were connected to the positive terminal of the lamp, the intensity of the light was very much reduced, and in the particular instance the ampère was eighteen with the lamp properly connected up, and only thirteen ampères when incorrectly connected.

THE earlier fault found with electric arc lamps when used for projection, namely, unsteadiness or flickering, have entirely disappeared with the introduction of the modern pattern hand-fed lamps and carbons of a homogeneous nature, and all the elaborations of clockwork and other automatic methods are now known to be superfluous, for perfect lamps for optical projection can be provided by the various combinations of feeding the carbons in the proper ratio of burning, two of positive to one of negative if both carbons are the same size, and one and a half to one, if the positive is larger than the negative, say 12 mm. cored to 10 mm. solid carbons.

IT is curious how old ideas are resuscitated. This was brought prominently to my notice when an artist who was a pupil of the late Mr. Child, of early dissolving-view fame, showed me an example of a large hand painting for the magic lantern which had been drawn on a concave glass like a watch glass. Theoretically it was thought that this would neutralise the distortion produced on the screen from the employment of simple lenses for the projection, but in practice the difference between it and one from a flat glass was practically nil, and hence the plan was not adopted. This par. may therefore be of interest to those who read some little time back in THE BRITISH JOURNAL OF PHOTOGRAPHY about this subject.

A most interesting exhibition of binocular microscopes of modern and curious type was given at a recent meeting of the Royal Microscopical Society, and, although not strictly within the domain of lantern matters, the microscope is so often used in connexion with the lantern for projection, and with the camera when taking photomicrographs, that a short account of some of the exhibits may not be out of place. The exhibition was instructive even to those like myself who are constantly in touch with all scientific instruments, and I think the President and Council are to be congratulated on getting together such a representative and interesting exhibit.

THERE were binoculars of the Wenham type, which, it will be remembered, has one body at right angles to the stage, and the other joined to it at an angle, also some Stephenson's binocular, were both bodies are at an angle, and the illumination of both fields of view are practically equal; the Nachet dissecting microscope, were a pair of eyepieces and prisms (mounted at the eye interval separation) are connected to a single tube as a T at the top; the Rousseler binocular, which had a convenient arrangement for manipulation when dissecting; and an historical binocular, by Murray & Heath, of a modification of Nachet's principle, which gave uncommonly good results. Messrs. Powell & Lealand showed what is seldom seen under binocular vision, viz., the circulation in valiscentaria; while Messrs. Watson showed a useful and interesting form of binocular, known as the "Brücke," which was designed mainly for flowers, tank use, and objects requiring low power.

A CLEVER adaptation of the Porro' principle of binocular vision was shown in Zeiss's new binocular microscope, which is fitted with two objectives as well as two eyepieces, the focal length being sufficient to permit of convergence of the two optical systems to one point of the object. The field of view was very good. This Porro system, which has so long been laying dormant, seems likely to revolutionise more branches of optics than field and marine glasses. It is strange how an optical arrangement, identical almost in every detail with that made forty years or so ago, has been resuscitated and made into a commercial success, also the subject-matter of a patent, which may or may not be a protection.

THIS system of prisms provides for the inversion of an image in a short form, and thus enables a telescope eyepiece to be used and a higher magnifying power obtained in the same space as a lower power would be with the ordinary (or Newtonian) form of binocular field glass with concave eyepieces. I remember fitting one of these inversion prisms to a single telescope fifteen or twenty years ago, to shorten the length of the instrument, and with the microscope development above described there are many possibilities of employing the system in popular optics if not as scientific research. In the collection of microscopes alluded to one would have been more pleased if greater attention had been paid to the adjustment of the Wenham prisms so as to ensure coincidence of image, and it was distinctly manifest how superior generally was the Stephenson system for obtaining binocular vision and evenness of illumination of the two fields.

G. R. BAKER.

#### A SMOKELESS MAGNESIUM FLASH POWDER.

THE flashlight powder which gives the least smoke is that which gives no ashes when burnt, beyond magnesium oxide. This is not the case with the usual mixtures of magnesium with nitrate, permanganate, or chlorate of potash, but a mixture of magnesium and ammonium nitrate should answer to the requirements, and experiments confirmed this assumption, and the development of smoke was considerably less than with the above substances.

Ammonium nitrate,  $\text{NH}_4\text{NO}_3$ , crystallises without water, but is somewhat hygroscopic; it is therefore necessary to melt the salt before use, and then to keep it, when powdered, in air-tight bottles. If it is not sufficiently dry, it does not burn quick enough.

The following mixtures were tested:—

- a. 1 part magnesium, 1 part ammonium nitrate.
- b. 1 " " " " " "
- c. 1 " " " " " "

The estimation of the illuminating power of these mixtures was arrived at with a sensitometer, with the result that *b* was equal to a mixture of 1 part magnesium and  $\frac{1}{2}$  of a part of potassium permanganate. Mixture *a* showed 2.4 times the amount of chemical activity of *c*, and the latter burnt more slowly. The rapidity of burning was generally less than with the above-mentioned mixtures of chlorates, &c., but absolutely sharp negatives were always obtained when *carte-de-visite* portraits were taken, and less powder was required.

The lens used was working at *f*-7, and the distance of the sitter was 2 metres, that of the flash powder being  $1\frac{1}{2}$  metres, and it was burnt before a mirror. On a sheet of zinc a strip of nitre paper, 5 m. long and 1 cm. broad, was placed, and the flash powder dusted on one end.

The shadow side of the sitters was lightened by paper reflectors. When the one end of the paper was lit, the exposure took place in a few seconds, and, if there was sufficient general light in the room, the eyes of the sitter appeared absolutely sharp. Focussing was effected by means of a candle at the same height as the sitter's eyes.

It was found that 0.3 gramme of magnesium, mixed according to *a* or *b*, gave fully exposed *carte-de-visite* negatives.

The development of the smoke was so little that five exposures could be made one after another, and this without trouble, and even then clouds of smoke were not noticeable.

If the flash powder be dusted on some pyroxyline or pyroxyline paper, it can be set fire to by a match stuck in the end of a bit of wood or a taper.

This smokeless flash powder ought to be useful for interior work, and, with 1 gramme of magnesium and 0.8 gramme of ammonium nitrate, a room with two windows and an area of five square metres, a sufficiently exposed negative was obtained, and the people in the room appeared absolutely sharp.

The essentials for success are absolute dryness of the ingredients, fine powdering, careful mixing with a feather on paper, and the use of nitre paper or pyroxyline.

PROFESSOR ALEX. LAINER.

Photographische Correspondenz.

#### COLOURING LANTERN SLIDES.

##### I.

WHATEVER prejudice may exist in the minds of some against the introduction of coloured slides in a lantern lecture or entertainment, there is no doubt that with the great bulk of the public such are greatly appreciated, and but few lecturers, having any practical experience of catering for the public taste, can be found who will not at once admit the truth of the assertion that coloured slides are popular with the masses, and it does not require any great stress of imagination for any one to see that, in the case of some subjects, very much of their interest depends upon the introduction of colour, notable examples of which we find in such subjects as flower studies, &c., &c. On the other hand, there is also a class of subjects that would certainly not benefit by their being represented in a coloured form—statuary, for instance, where so much depends upon the blending of half-tone, high lights and shadows, and in the original of which, no colour being present, it becomes somewhat incongruous to introduce such—although this mistake has been perpetrated frequently, even with high-class slides. Neither does it follow that any lantern lecture set must of necessity be composed entirely of either coloured or uncoloured slides, for experienced lecturers never hesitate to introduce in a set, the bulk of which are uncoloured, a few coloured pictures, the subjects of which are more particularly suitable for being exhibited in coloured form, whilst a few of such always tend to break up a monotonous series of views, and are likewise restful and pleasant to the eyes of beholders; and, so long as coloured pictures are appreciated by the general public, so certainly will their production form an important feature with lantern-slide makers.

The colouring of lantern slides is an operation that requires a considerable amount of care, and some practice is needed before any one need expect to become proficient at the work. Many years ago, or before the introduction of the now popular gelatine plate, this work had to be accomplished upon a collodion film, and, with a large number of professional makers and colourists, has still to be practised; but within recent years, among amateur workers especially, gelatine is almost universally employed in the making of their lantern transparencies, and the treatment in the case of slides made upon a gelatine base differs somewhat from that in regular practice upon collodion. No doubt, most beautiful results are obtainable by either method, even although our old workers are loth to admit that gelatine can at all compare with good old collodion in this branch of photography.

Among the great bulk of amateur workers a large number, no doubt, could be found who have, from time to time, tried their 'prentice hand at colouring their slides, and quite possibly with a fair amount of success. There are, however, certain professional secrets in this work which, if unknown to any one undertaking it, make all the difference in the world in the results produced.

In dealing with gelatine, for instance, the operation is too frequently undertaken without any, or a proper amount of, thought being bestowed upon the condition of the slide being suitable for the application of colour; and, in cases where an unsuitable condition exists in a gelatine slide, it is impossible for any one to obtain that sparkle or brilliancy which ought to form a part of all first-class results.

It has been over and over again urged that the great advantage which collodion possesses over gelatine lies in its purity of high lights, as well as a certain or peculiar cut of image, which no gelatine slide ever can be made to yield, so long as the image is not built up on the film, as is the case with the deposit which forms the image on a collodion film. The chief drawback, however, when attempting to colour a gelatine film, will almost invariably be found to lie in the absence of absolutely clear glass in the high lights; if there be any muddiness apparent, such is certain to be more or less intensified by the application of colour. Therefore, whenever this degradation of the high lights is found to be present in a slide it is desired to colour, the first step an expert colourist will take will be to subject the same, if at all possible, to some treatment whereby the high lights are made suitable for the rendering of an absolutely transparent appearance when colour is applied to the same.

There is also another very important operation in connexion with the successful rendering of coloured subjects that I have never seen any writer upon the subject refer to. Take, for instance, the colouring of a subject such as a steamer with red funnels, or various-coloured smoke-stacks. Here we are met with a difficulty which to some may appear insurmountable, by reason of the original red colour of the object when photographed being so non-actinic as to yield the appearance of the funnels being quite black in the photograph when the negative is printed, either upon glass or paper, and, when in the case of a lantern slide the same is produced without any special preparation, the deposit on the slide will be quite black and opaque; and, when to this is added any red or coloured pigment, no appreciable colour can be represented by transmitted light upon the screen, by reason of the opacity of the dark funnels. Instances of this kind, therefore, call for especial treatment, frequently entailing a considerable amount of skill and experience, which many workers do not care to impart to the public at large. In the case of collodion the scalpel requires to be frequently used to obtain particular high lights, or to provide certain portions of a picture being brought into a fit condition to yield a transparent coloured image giving a truthful representation of the original, such as would be the case in the example stated, viz., a steamer having bright vermilion-coloured funnels. With a gelatine base the scalpel cannot be employed with success, by reason of the walls of the gelatine being so much deeper than those of collodion, so other means have to be provided to produce the high lights in view of the objectionable opacities. With gelatine an instance of this kind is best treated by working upon or doctoring the negative, whereby, instead of the same yielding a slide with black funnels, the same will print this portion of the steamer as clear glass. To accomplish this, the funnels in the negative must be blocked out with a suitable opaque medium, such as burnt sienna; but bear in mind, in doing this, so as not to injure the negative, or to make it at all unsuitable for regular printing, after the slide has been made, that only oil colour be used for such blocking out. When oil colour is used on the film side, a rag steeped in turpentine will remove any trace of such treatment, and leave the negative uninjured. Other instances will be met with, such as when no negative can be obtained, in which case such treatment has to be communicated by an extremely delicate operation of reducing the opacities on the face of the slide itself by one or other of our well-known reducers, such as ferricyanide of potassium. For successful results, the obtaining of these high lights so absolutely clear as will permit of a bright transparent condition being secured is the first necessity in lantern-slide colouring, and no one need attempt to become a successful colourist, or produce coloured slides of really first-class quality, that does not grasp the necessity of having this groundwork to operate upon, both in gelatine and collodion. But, whenever this keystone of the bridge is passed, then lantern-slide colouring becomes a matter requiring ordinary patience and cleanliness to accomplish satisfactorily, once a knowledge of the necessary colours and tools to use is obtained. T. N. ARMSTRONG.

#### JUDGING A LANTERN-SLIDE COMPETITION.

A CONTEMPORARY says, "It was no easy task for two gentlemen who kindly acted as Judges to patiently sit for some hours in order to make their awards."

In a dark and dismal chamber beneath the boards whereon the editorial chair reposed in the odour of sanctity: we sat. It was a drear December day, and the fitful light of the fading sun was dimly reflected

through the prismatic pavement above us, but a ray of shining comfort glowed in a distant fire made for our especial benefit, and we clapped our hands and stamped our feet on the concrete floor in sympathy with burning embers as we waited the magic light being thrown upon the sheet which, I may here remark, had been borrowed from the office-boy's mother for the occasion.

There were two of us, and the editor, whose kindly thoughtfulness had supplied our minds and stomachs with good feelings and good fillings respectively, in anticipation of the coming events that were to cast their shadows upon the screen.

The wintry wind wearily whistled down the unprotected stair, the man with the George Lewis fur-liner smiled the smile that was childlike and bland, the staff of the outer office, who came down to assist in the show, turned down their trousers to keep their ankles warm, and turned up their coat collars to keep the cold from their necks, but the chief merely stroked his hair.

We were obliged to sit in this chamber because it was dark and big enough to hold the lantern, and so show the pictures properly. Around us on every side were stacks of slides in boxes sent by competitors, and all was ready to begin. The chief turned on one or two little taps, and adjusted the lime light that hissed loudly; but this was nothing to the hissing sound that escaped the editor's lips a moment or two later, for he had, whilst stopping to regulate the light, forgotten the existence of a small gas jet (which was for use in case the electric light failed) in close proximity to his head. First there was a little hissing sound, as I have said, from the lime light, then a slight frizzling noise, and a smell of something burning; then there were a few "cursory" remarks upon swearing, edited by the lanternist, and which were carefully treasured by his tittering staff for future use in case of emergency, new and original anathemas being now at a premium.

By this time we were on the tiptoe of expectation, and fearful lest something untoward might happen. I had a premonition of various disasters ere we started, and I am quite convinced now that I have mistaken my vocation, and ought to have been a professional clairvoyant. The first interruption came about like this: The second slide had scarcely slid slowly in the slot, and shone upon the screen—I mean screen—when my colleague interrupted the proceedings by informing me that I had wrapped my feet in his *Morning Advertiser*, and that he was anxious to preserve it, as there was a particularly fine piece of alliteration in it. After I had returned his paper, the judging proceeded, and I will try and describe some of the scenes that we saw and think, in ink, the thinks that we thought.

The competition was divided into the usual number of classes, but those that particularly appealed to me were the Animal, Figure, and Portrait series.

The Animal class came first, and, that unlucky second slide having departed, all went merry as a modern musical play until there flashed on the screen a splendid picture of a long-eared critic of the *Weekly Thistle*. There was silence for a moment; the editor moved his head in our direction, as much as to insinuate, almost in the words of Macbeth, "When will you three meet again?" when the quietude was broken by the dulcet accents of the office boy (who had evidently forgotten for the moment in whose presence he was), saying, in a voice of agitated interrogation, "When is a Scotsman like a donkey?"

The rest of the staff were struck dumb with amazement at the boy's audacity, and, as no sound escaped us, the irrepressible urchin answered his own question *sotto voce*, but with triumph in every syllable, "When he stands on his banks and braes." There is now a vacancy in the outer office, and the Manager, and the Assistant Manager, and the Assistant Manager's assistant are exercising their ingenuity to concoct an advertisement for the front window.

They showed me, later on, their attempt in this direction; here it is: "Wanted, immediately, an office boy. No amateur photographer eligible. One who is deaf and dumb preferred."

I suggested that they should add, "No boy who can whistle need apply." I know it would be a little awkward to have to write directions for a deaf-and-dumb boy, but look what a few mistakes he would make in comparison to other office boys, and what a comfort to the neighbourhood he would be—only just fancy it, an office boy who could neither talk nor whistle! Ye gods! 'Tis a consummation devoutly to be wished."

After the office boy had been kicked by the various managers and their assistants, and his remains buried in the coal cellar, we proceeded. The next picture of note that I can remember was that of a man and a cow. I forget the name of the subject, but I know the cow had her tongue out and was licking the man, and it recalled to my wandering wits the old nigger minstrel story of the wonderful sagacity of animals. It was a story of a cow who had lost her calf, and a man found it and took it back to her, whereupon the cow turned to the man and licked him (an *l* there, Mr. Printer, please, not a *k*, it makes a lot of difference to the story). Brother Bones No. 1 said that was an example of the sagacity, the gratitude of the cow. Brother Bones No. 2 disputed it, saying it was not gratitude at all, there was no sagacity about it; the cow had only licked the man because she thought he was her calf—a case entirely of mistaken identity; and the slide above referred to reminded me very vividly of this tale, which, by the way, is not quite

new, as I last heard it told by my father to my mother over my cradle in the dim and distant distance.

The show shone on, and there were pictures of all kinds of animals, from the elephant to the flea. The "elephant" slide came just before the last-named, and, when it disappeared rather quickly, there was a rumbling noise near the coal-cellar door, and a cheery voice was heard in mild remonstrance. It was that office-boy again. He had bored a hole with his corkscrew knife through the door, and was having a fine view at the show in spite of us all. His remark here was more expressive than polite; he said: "Who are you shovin'?" as the elephant said to the flea. As the little urebin was rather dirty, they ducked him in the editor's hypo bath, and he went home a sadder and, let us hope, a wiser and better boy. We indulged in soda of another form during his washing process.

Other slides represented a sweet little maid in deep conversation with a beautiful pony, whose soft eyes plainly said "Sugar." A monkey, who had evidently taken out a search warrant to permit him to investigate the state of his master's spirit cabinet—he (the monkey) was leary and bleary, and presumably "beery" also.

There was a remarkable picture of two dear little dicky-birds sitting on a stile, so close together that you could not tell 't'other from which, they looked exactly like Siamese Twins. And then there was the sailor and the parrot, not the one dear to our nursery days. This sailor was evidently teaching the parrot to swear; you could almost see the painful profanity dropping from the parrot's beak, so wicked did it look.

By the way, in the Architectural class there was another parrot, which had quite a startling career, through a series of slides. [N.B.—This story has been copyrighted, as I had reason to believe that the editor of a contemporary, who has several speeches to make at a certain dinner next week, was about to crib it.]

The scene was laid in a country house. The curtains were closely drawn in a snug little room; the rain could be heard pattering against the window pane without, and the flickering blaze of the firelight disclosed, in slide No. 1, a parrot asleep in its cage in the window, and a terrier slumbering peacefully on the hearthrug. In slide No. 2 the parrot had evidently woke up, and was considering things in his wise way, came to the conclusion that things were a bit flat, and, catching sight of the terrier, according to the note on the margin of the slide, ejaculated "Rats, doggie; rats!"

The next picture showed the dog rushing about the room (oh, for the cinematograph for this subject!), evidently in search of the intruding rodent, which, however, was conspicuous by its absence.

Slide No. 4 shows a snarl on the face of the tiger—I mean terrier, as it subsides once more into slumber, and the parrot bides a laugh by putting its head under its wing.

Slide No. 5 is a repetition of No. 4, but the dog is not having any, and the growl only is visible on his face, and pain on the face of the parrot.

No. 6 shows us the parrot descending from its cage.

No. 7.—It reaches the dog, and stealthily bites its ear, saying, at the same time, "Rats, doggie; rats!"

No. 8 shows us a bundle of feathers all stained with blood on the hearthrug, with these words on the margin: "Parrot (*log*):—'I know what's the matter with me. I talk a darned sight too much.'"

The landscape school now hove in sight, and the beautiful pictures reminded me of those expressive lines of Mr. Shakespeare-Bacon, when he wrote:—

"Slowly sliding on the sheet,  
Slush and snow, and landscape sweet;  
Wishy-washy things were few,  
Tho' we looked 'em thro' and thro'."

The landscape series distinguished itself by one slide alone. It represented something like a desert island, with the figure of a man, whose costume was more picturesque than useful, reclining on the seat with which nature had endowed this uninhabited island. The glorious sun was silently sinking to sleep in the west, and illumined the wreckage that was strewn around. Numerous casks were there, with these strange devices upon them, XX and XXX. The scene was well arranged, but there were two deficiencies: first the title was all wrong. It was called *The Widower*, suggested by the strange story of Bluit le Boosemon. It was, no doubt, well meant, but who would have thought that the operator would neglect to block out the brewery and chimney in the distant offing?

Speaking of a chimney reminds me that we were allowed to smoke certain fragrant weeds provided by "the House," but more, I think, as a disinfectant against any malarial microbes that might lurk hidden in the dark corners of the cellar, but I am quite sure none could survive the smell of those cigars; in fact, one of the staff, after three puffs, suddenly recollected that he had a message from his wife to the chemist close by, and we saw him not again that day.

Now I will pass on to the port and figs, or, to be more explicit, to the portraits and figures. The first portraits showed us that the instincts of maternity were prevalent amongst the photographic lanternists, the picture of mamma-in-law with the son and future prop of the amateur's declining days in her arms smiled benignly upon us. Now, when a man marries, he usually has a magnificent portrait of his mother-in-law in the most conspicuous place on the drawing-room mantelpiece. If

he is a photographer it is taken by himself, but he gets wiser in time when the ties of kinship become the knots of dissension. After a little time the photograph gets put in a less prominent place, till ultimately it is discovered either on the rubbish heap in the back garden or in the lumber room, and when the latter is turned into a nursery the photo is given to the baby to help cut its first tooth. Such is the decline and fall of the maternal relative once removed.

You will say, reader, in your own mind, What has all this got to do with photography? I reply, "A lot." People who go to all the trouble and expense in arranging lantern-slide competitions do not want portraits of other people's families and babies, and mothers-in-law, and sisters, and cousins, and aunts in inartistic groups, with big feet and hands and fat white faces that look like pieces of paper with dots for eyes, nose, and mouth, the inevitable results of amateur "group" photography. These things are interesting to the people themselves, but cannot be tolerated in a lantern show.

Then we had the portrait of the artist's old flame, called by Kipling Helen Blazes: and she looked it. The light went out when the smile of a nurse flashed on the screen. She was holding the inevitable son and heir, and her expression was "frequent, and painful, and free," as Bret Harte says, and you could imagine her saying to her infantile charge, "Cough it up, ducky."

We finished up by two marvellous pictures of lightning from America, and even the electric meter in the cellar was palpably disturbed during these exhibits. They got a special medal, and, had you seen them, you'd say they well deserved it.

ST. MARTIN LAMUS.

## LANTERN SLIDES AND SLIDE-MAKING.

[Paper read before the Sixteen Photographic Club.]

I do not think that the subject of lantern-slide making needs any defence, for, although some extreme photographic artists deny that a lantern slide can be a picture, it is a hobby from which a great amount of pleasure can be obtained, and which exercises an increasing fascination over those who practise it.

I propose this evening to confine my remarks to the treatment of gelatino-chloride and bromide plates, as, among amateurs at any rate, they are used to a much greater extent than any of the other processes, and results may be produced equal to the best that can be obtained from collodion.

I suppose that the great majority of photographers use a hand camera, either alone or in addition to one of larger size, and these have an advantage in the ease with which they can make lantern slides from their small negatives. I do not mean to say that these negatives would not often make a better picture if reduced; but, if the contact method is alone used, pleasing slides may be produced from a large proportion of them.

### REDUCTION OR CONTACT.

Opinions are very much divided as to the superiority of slides made by reduction in the camera over those made by contact. One argument against the latter is that the glass used for plate-making is sometimes not absolutely flat, and therefore it is impossible to obtain perfect contact, resulting in a slight loss of sharpness in the slide.

I believe that this objection is more theoretical than real, but the difficulty can, to a great extent, be got over by exposing at a greater distance from the source of light, and avoiding side reflections by placing the printing frame at the end of a deep black-lined box. In ordinary slide-making, however, it is quite unnecessary to do so. For dark tones, I think gas is the best illuminant, except, perhaps, for very dense negatives, when magnesium ribbon may be used. In making a slide from a negative with great contrasts, expose much closer to the light than usual, about six inches from gas or one foot from the magnesium, and give a rather full exposure; by this means it is often possible to obtain presentable slides from very hard negatives; thin ones, on the other hand, should be printed from a greater distance, and, if very thin, a rather weak light should be used, of course increasing the time of exposure accordingly. With thin and flat negatives, however, over-exposure must be avoided, as greater contrast in the slide is to be aimed at. For warm tones the exposure must be greatly increased; from four to eight or ten times that required for blacks may be given, the warmth of colour increasing with the length of exposure, and magnesium ribbon should be used except in the case of very weak negatives, when gas will give a better result.

For reducing by daylight the simplest apparatus is a board with a frame at one end to hold the negative. A quarter-plate camera is adjusted at the requisite distance, and fastened with the tripod screw to the board, and, if a narrow slot is cut in the latter for about half its length, the camera can be moved nearer or further from the negative, according to the amount of reduction required. The whole is pointed towards the sky and the exposure made. It is rather difficult to give an estimate as to the time required. At this time of the year, on a bright day, with a fairly quick-printing negative, using Thomas's plates, reducing from whole-plate with the lens working at f-11, about  $\frac{1}{2}$  minute would be enough for a black-toned slide, and for brown tones 5 minutes or more according to the colour wanted. For reducing by artificial light, a lantern with a con-

denser of sufficient diameter to cover the whole of the negative is certainly the most convenient system; but, as there are not many who have one large enough for half-plates, and still fewer for the larger sizes; there are other methods by which reduction by artificial light can be carried out.

One way is to place a piece of ground glass about three inches behind the negative, and to pass a strip of burning magnesium ribbon backwards and forwards, and up and down, at an inch or two behind the ground glass, taking care to make the illumination as even as possible, the amount of ribbon used depending on the density of the negative and the colour required in the slide.

Another way, and, if time is not much object, perhaps a better, is to place an incandescent gas burner, or a good lamp, on each side of the negative, just far enough back to prevent the rays striking the glass. A piece of white cardboard, or ground opal, is then stood up in the position which will best reflect the light through the negative and give the strongest and most even illumination. Very good results may be got in this way, but the time required is rather long; for brown tones, with the lens at  $f/11$ , about 20 minutes will be necessary for an average negative on Thomas's plates.

The usual definition of a perfect slide is that it should be clear glass in the high lights, and that there should be a regular gradation of density in the shadows, which must not, however, be quite opaque in the darkest parts. I think that the amount of clear glass should be very small, and, in fact, it is often an advantage to have a slight veil even over the highest light, giving a softer and less glaring effect. It must be admitted, however, that at many lantern shows the brilliant slides, and those showing the greatest contrasts, are often preferred by the "audience" to the softer and more pictorial ones.

#### SKIES.

Years ago it was the fashion to produce slides in which the sky was represented by an expanse of white, without clouds or shading, but fortunately taste has changed, and we do not see so many views on the screen with the blank skies of former days. In printing in clouds several things must be considered. I am supposing that there are no printable clouds in the negative. There is often a temptation to use a sky which has contrasts much greater than the landscape it is supposed to belong to, and the effect is usually very disastrous. I show you here an example of how it should not be done. Care must also be taken that the sky and the view are both lighted from the same direction, and that they meet properly at the horizon. It is also an advantage if the lines of the clouds can be made to balance the lines of the landscape. I think it is better to err on the side of lightness rather than too great density, for except, perhaps, in some open landscapes and sea pictures, the view is the most important part of the slide, and the clouds should not be so prominent as to distract attention from that portion. If it is not proposed to have clouds in a view, and the sky part of the negative is even and free from markings and not too dense, it is a good plan to let the sky in the slide veil over considerably. Directions are often given to remove the plate from the developer as soon as the high lights show any signs of veiling; but I think that, if the sky is slightly darkened all over, the result is greatly superior to an expanse of bare glass.

Many people have very exaggerated ideas of the difficulty of printing clouds on lantern slides. By careful masking they may be printed on the same plate as the view, but there is some difficulty in timing the exposure so that the whole slide will develop equally. A far easier plan is to keep the sky part of the view clear glass, and to print the clouds on a separate plate, which is afterwards used for the cover glass. In working this way it must be remembered that the clouds are viewed through the glass instead of the usual way, so that, in choosing the cloud negative, it must be looked at from the film side for the direction of the lighting, &c. The lantern plate and slide should be held, back to back, up to the yellow light, and the limits of the view marked with a pencil on each edge of the lantern plate, a line on the film about  $\frac{1}{8}$ -inch long is sufficient as a guide. The plate is then placed in the printing frame in contact with the cloud negative, and the lower portion masked off with a folded cloth, keeping the line of the view as nearly as possible, the marks on the edge of the film showing the amount of the plate that must be covered. It is advisable to give the part near the horizon rather less exposure than the upper part receives, by moving the cloth slowly up and down for a short distance. The time of exposure requires some care, or the clouds will develop with a different tint than the landscape, and that is the chief drawback to this method. Should they appear too warm, they can be slightly toned with gold, which will often bring them to the right colour, taking care to stop toning before they are quite cool enough, as the tone is colder when dry.

After development and fixing, the cloud slide and the view are held back to back, and any part of the cloud projecting over the landscape is cleared away with reducing solution, applied with a small mop of cotton-wool or a soft brush, and with a little care a very exact joint can be made. If the clouds have been over-developed they can easily be brought to proper density with the reducing solution, and the lower portion lightened if necessary, but be careful to avoid over-reduction, as the solution acts rather quickly on weak prints. The reducer used with a brush can also be locally applied to any part of the slide which is too much veiled, or which has acquired too great a density. I may mention here that the perchloride of iron reducer is not suitable for warm-toned slides on

bromide plates, as it changes the colour to a blue tint, but Howard's Farmer's ferricyanide and hypo reducer will do all that is required.

#### MASKING.

It is surprising sometimes to see how little consideration is given to the masking of slides. You may occasionally, at a lantern show, see a number of slides exhibited by some one who has apparently purchased a box of assorted masks, and who feels bound to use them all up before buying another. Some of them may suit the views, others certainly do not, but the box must be finished. Beginners often make the mistake of using too large a mask, they do not like to sacrifice any part of the plate they have just developed; but there are really comparatively few instances in which the whole of the slide can be shown to advantage, it is nearly always better to cut off part. I am only referring here to pictorial subjects, and not to scientific slides, which, of course, will often require the whole of the plate. I think that by far the best shape is the oblong, with square, and not rounded, corners; the latter do not give nearly such a pleasing effect on the screen. Round, oval, square, and dome-shaped masks are useful for classes of subjects such as microscopic work, still life, some portraits, &c., but they are only occasionally suited for landscapes.

The colour of the slide should also receive some consideration. Warm brown or red has a curious effect if used for snow or frost studies, these are cases for black or grey tones. Architecture, or at any rate interiors, is usually more effectively rendered in not too warm colours. I must own to preference for brown tones myself, which I like to use when possible; but, after all, the colour is chiefly a matter for individual preference.

#### CHLORIDE PLATES.

Whether warm or cold tones are used, however, it is a good plan to have a few of the less-favoured colours interspersed among the others, so as to break the monotony in a long series of slides.

Among dry-plate workers chloride plates are often used for making slides by contact, both on account of the great latitude allowable in exposure and the long range of colours obtainable. The chloride film is more translucent than the bromide, and is of a salmon colour when held up to the light, and one very noticeable characteristic of slides made on these plates is the remarkable transparency of the shadows.

Although chiefly used for contact work, they are quite suitable for reduction in the camera with a rather prolonged exposure. To produce a warm brown tone, an exposure of about twice as long as would be given to a Thomas's plate for the same colour would be necessary. For contact work the best illuminant is magnesium ribbon, as by ordinary gaslight the exposure is rather prolonged; an average negative would need about three minutes at six inches from the burner.

Another point of difference between chloride and bromide plates is that for the former it is not necessary to alter the developer according to the colour required; it is entirely dependent on length of exposure. With the same developer a series of tones can be got, ranging from greenish-black through various shades of brown to a bright red. To obtain a very deep red, however, I think it is better to considerably restrain the developer by adding two or three grains of potassium bromide and ammonium carbonate to each ounce; I am supposing hydroquinone to be used as it is generally recommended, and for chloride plates is preferable to pyro. The developer is used in a more diluted form than for bromide plates and with less accelerator. The Ilford Company give a good one on their Alpha plate boxes; or, if the Ilford universal hydroquinone developer is used, take one part of the quinol solution, half part soda solution, and two parts water, and with this developer and various exposures almost any colour can be got. If black tones only are wanted, amidol or metol will give a better colour than hydroquinone. I have heard it stated that one of the great charms of Alpha plates is the pleasing uncertainty of the colour to which the slide will develop. This is to some extent true when commencing the process, but with very little experience there is not much difficulty in judging the correct exposure for the tone required. In any case, so long as sufficient exposure has been given, it does not much matter if the slide is considerably warmer than is wanted, for chloride plates are especially suited for toning with gold. They may be toned in separate baths or in the Ilford combined-toning and fixing bath; I prefer the latter, and it is not liable to double-toning. The brightest red can be gradually changed to brown, black, or blue, the latter requiring a considerable time in the toning bath.

One advantage of these plates is the amount of light that may be used when developing; it is only necessary to have yellow glass in the lamp for judging density, and there is no harm in having an unprotected light in the room if care is taken that the direct rays do not strike the plate before it goes into the developer. They are especially useful for slides of flowers or still life, and for some landscapes, but are not so generally used as their merits deserve.

#### BROMIDE PLATES.

There is no doubt that the great majority of amateur slide-makers use bromide or chloro-bromide plates. I should think it is no exaggeration to say that they exceed all the others put together. Most makers supply plates of two rapidities—rapid for black tones and slow for warm tones. With the rapid plates very pleasing brown colours can be obtained with a long exposure and restrained developer, and the slow series will give

good warm blacks with a short exposure and quick development. For pure cold blacks the newer developers, such as metol, amidol, and rodinal, give the best results; hydroquinone also gives a good colour, and pyro may be used where rather more warmth is preferred. The solution for developing slides must be weaker than that used for negatives, generally about half the strength, and with most plates the development must be carried further than appears necessary in the unfixed slide, as the hypo bath often has an apparently reducing effect. Any slight veil over the sky and high lights will be hardly visible when the slide is fixed, and can usually be ignored. With the newer developers a rather shorter exposure should be given than when using quinol or pyro; a full exposure is very likely to lead to considerable veiling of the lights with a consequent over-flattening of the slide. A safe guide in the choice of a developer is to use the one recommended by the plate-maker, but I find that an average developer will suit most of the kinds of plates that I have tried. The great thing to learn is when to stop development. It is not a thing to be learned from books or verbal instruction, but comes with practice. There are far more plates spoiled after they go into the developing dish than by the exposure, and among beginners, at any rate, the fault is in not developing long enough.

The production of brown tones is dependent on long exposure and restrained development; the longer the exposure and development, the warmer is the tone.

#### DEVELOPMENT.

The favourite developers for these colours are hydroquinone and pyro, used with the addition of considerable amounts of bromide and sometimes ammonium carbonate. For my own use I prefer pyro ammonia. Thomas's old formula, made up of pyro sulphite ten per cent. solution, 30 m.; ammonium bromide,  $4\frac{1}{2}$  grains; ammonium carbonate,  $4\frac{1}{2}$  grains; ammonia, 8·803 m.; water to 2 ounces; for redder tones more bromide and ammonium carbonate is added, with, of course, increased exposure.

There is some difficulty at first in judging the depth to which development should be carried, and it varies greatly with the make of plate used. The appearance of a fully developed Ilford special plate treated for brown tone would be quite different to a Thomas's plate developed for the same colour. The Ilford plate should look rather weak, and the other make fully dense; in the first case you have a bromide plate, and in the other, I believe, a mixture of chloride and bromide emulsion; but, as I said before when speaking of black tones, do not stop development too soon, for the richness of the colour depends largely on the time required to obtain density, a slide that has developed too quickly is often a poor and rusty-brown colour. A good slide will often take 10 minutes or more, and, if the acid fixing bath is used, it will clear away any slight stain there may be from the pyro. With hydroquinone there is no fear of staining, and the same developer may be safely used for two or three plates; but care must be taken that the exposure is sufficient, or there is some risk of the slide being rather hard, the colours obtainable are very good.

Thomas's is a useful formula, and is as follows:—

#### No. 1 SOLUTION.

Hydroquinone .....	160 grains.
Sodium sulphite .....	2 ounces.
Citric acid .....	60 grains.
Potass bromide .....	40 "
Water to .....	20 ounces.

#### No. 2 SOLUTION.

Sodium hydrate .....	160 grains.
Water to .....	20 ounces.

For black tones take  $\frac{1}{2}$  ounce of each and 1 ounce water; for brown, add  $1\frac{1}{2}$  grain each of ammonium bromide and ammonium carbonate, and, for warmer tones, increase the amounts up to 9 or 10 grains of each to the 2 ounces of developer; the full amounts of restrainer will require a very long exposure—about five or six times as much as would be given for a rather cold brown, and will probably take a quarter of an hour to develop. In very cold weather it is advisable to use a little warm water in making up the developing solution, as many developers act very slowly when very cold; pyro is, however, to a large extent an exception. If a slide gains density very slowly in cold weather, it is a useful but unscientific dodge to rest the dish on the top of the dark-room lamp for a minute or two so as to raise the temperature slightly—I have often saved slides that way. If you are developing a slide to a brown tone, and through under-exposure it will not come out properly, and only appears as a ghost, pour the developer off, and pour  $1\frac{1}{2}$  or 2 ounces of water into the dish, cover it from the light, and leave it to develop in the plain water for a quarter of an hour or so; if you look at it then, you will probably find a nearly fully developed slide. The colour will not be quite as good as if finished in the ordinary way, but will be quite presentable, and a plate may often be saved in this way which would otherwise have been cleaned off for a cover glass.

#### TONING AND FIXING.

For fixing, either a plain or an acid hypo bath may be used. I prefer the latter myself, as it is of great assistance in removing any possible slight stain after pyro development. The formula is: Water, 20 ounces; hypo, 5 ounces; soda sulphite, 1 ounce. When dissolved, add while stirring vigorously 1 drachm sulphuric acid.

For thorough fixation the slide should be left in the solution two or three times as long as it took to clear, and is then examined for density, colour, &c. If it is not all that it should be, or at any rate only very slightly faulty, the very best remedy is to make another; but, if the colour is satisfactory and the fault only a little too much density, it may be reduced. A good reducer is Howard Farmer's, consisting of 10 per cent. solution hyposulphite of soda, with sufficient ten per cent. solution potassium ferricyanide added to turn it a pale yellow. The action must be watched carefully, as, if too much of the ferricyanide has been added, it is very rapid, and immediately the reduction is sufficient the plate must be well washed in running water. For washing after fixation I think two hours in running water is quite sufficient, and the best form of washer is one in which the water is continually passing over the plates. When the washing is finished, each slide should be given a good final rinse under the tap, and, while the water is running over it, the surface is mopped with cotton-wool or gently rubbed over with the fingers to remove any particles or grit which may be adhering to the gelatine, they are then stood on edge in a warm place, well protected from dust, to dry.

If the slide appears of too warm a colour, it can easily be toned with gold. The Alpha bath is simple and effective. The formula is:—

Hyposulphite of soda .....	2½ ounces.
Acetate of soda .....	1 ounce.
Ammonium sulphocyanide .....	1 "
Gold chloride .....	4 grains.
Water .....	10 ounces.

The salts are dissolved in the water in the order given, and the bath will keep for a considerable time in the dark. In toning from brown-red to brown, the slide must be removed and washed as soon as a slight perceptible toning action has taken place, as the colour is much colder when dry; for a black, the toning must be stopped while the slide is still brown-black; for a bright blue, it may continue until a decided blue colour is obtained, which will be more intense after drying. With this bath slides may be fixed and toned at the same time or may have been fixed and dried previously. The sulphocyanide bath may also be used, but much stronger than for P. O. P. The formula is:—

Water .....	1 ounce.
Ammonium sulphocyanide .....	20 grains.

When dissolved, add slowly—

Chloride of gold .....	1 grain
in Water .....	1 ounce.

Before toning with this bath the plate must be well washed to remove the fixing solution.

To tone slides from black to brown, uranium nitrate is used. The formula is:—

Uranium nitrate .....	1 grain.
Potassium ferricyanide .....	1 "
Glacial acetic acid .....	15 minims.
Water .....	1 ounce.

With this solution a black-coloured slide can be toned to various shades of brown and finally to red; the toning should be carried slightly further than the colour required, as there is some reduction of colour in the final washing, which should not be continued longer than is necessary to remove the yellow stain from the clear portions. The slide should be rather lightly developed, as uranium toning has also an intensifying effect. These colours can be changed to green or blue by immersing the toned and washed slide in a weak iron solution, i.e.—

Strong solution perchloride of iron .....	2 minims.
Hydrochloric acid .....	4 "
Water .....	10 drachms.

As soon as the shade of green or blue wanted is reached, the slide is at once washed for five or ten minutes and dried. On removing uranium-toned slides from the washing water they should be gently dabbed over with a pad of soft cambric, free from dust, to absorb as much of the moisture as possible, otherwise the colour will run and spoil the outlines. They are then dried, and, I think, will be found quite permanent.

A. P. HOOLE.

#### INTERNATIONAL LANTERN-SLIDE EXHIBITION.

THE Committee of Administration of the Association Belge de Photographie have decided to open this year an international competition for lantern slides. The rules will be published next month, but, provisionally, three classes have been decided upon: Artistic Photography, Scientific Photography, and Architecture. In each class there will be silver-gilt, silver, and bronze medals placed at the disposal of the Judges for the best set of twelve slides. Slides may also be sent for exhibition only. The competition will close on October 31, and the slides must be left in the hands of the Association till the end of February 1900, in order that they may be shown before the seven sections. The slides must be either of the size determined by the International Congress,  $8\frac{1}{2} \times 10$  cm., or else of the English size. The rules may be obtained on application to M. Vanderkindere, 97 Avenue Brugmann, Brussels.

## STEREOSCOPIC EFFECT ON THE SCREEN.

THE latest device with this object is due to Dr. G. R. Wilson, of Loanhead, who, in carrying it out, proposes to obtain series of photographs of moving objects, taken from different points of view, after the manner of stereoscopic photographs of stationary objects. The cameras employed are cinematograph cameras so arranged and geared together as to operate synchronously, and to produce two or more series of pictures simultaneously.

These cameras will be geared together by chain or other suitable gearing, or they may be driven by a common motor with simultaneous stops, that is, with an electrical or other mechanism which will ensure that the two or more cameras keep exact time. The negative, film, or strip in each camera so used, and the shutters, which alternately admit and exclude the light, will work synchronously, so that in any given time each camera will take exactly the same number of photographs as the other camera or cameras.

Dr. Wilson proceeds: The negatives from this stereoscopic cinematograph camera or cameras will be printed on cinematograph slides, films, or strips. I may print the corresponding images on one slide, film, or strip, side by side, or I may use separate films or strips.

The slides, films, or strips, I cause to be run through sister lanterns placed near one another, so arranged that the images projected from the two or more lanterns are superimposed, or approximately so, upon a screen.

The lanterns used will be some form of cinematograph lantern, that is an optical or magic lantern having a mechanism by which the slide, film, or strip bearing the successive pictures, is rapidly passed in front of the light, so that the pictures are projected on the screen in rapid succession.

As the cameras were geared together so as to obtain simultaneous negatives, so the cinematograph lanterns will be geared together so as to throw the corresponding pictures simultaneously upon the screen.

Each cinematograph lantern will be geared to each of the other lanterns; or they may be driven from a common motor. I may use ordinary chain gearing, so that each link in the gearing chain will pull upon a tooth or a toothed wheel, so as to revolve it through a definite arc of a revolution; or I may use an electro-magnet, which, by establishing connexion with the driving wheels rhythmically, will stop the revolutions of the several lanterns coincidentally and at regular intervals; or I may employ other means for driving the lanterns synchronously.

Instead of using separate cinematograph cameras I may use a double, triple, quadruple, &c. camera, with cinematograph adjustment, that is, a camera capable of taking more than one series of pictures simultaneously.

Similarly, instead of separate lanterns, I may use a double, triple, quadruple, &c. cinematograph lantern to project the different series of pictures.

Pictures so projected would appear blurred upon the screen, and would give no stereoscopic effect unless differentiated in some way in the lanterns, and again resolved by some device in front of the eyes.

Into each cinematograph lantern, therefore, I introduce an apparatus for polarising the light, such as was described by Anderton in the specification of his patent for stereoscopic lantern, No. 11,520 (1891); or I may use differently tinted glass or other screens; or I may use some other method for differentiating the superposed pictures projected from the separate lanterns or lenses on to the screen, which I prefer should be a grooved or striated silver screen, but which may be some other kind of screen if desired. For inspecting the images thus differentiated on the screen by polarisers, tinted glasses, or other means, the spectator is provided with analysers or other instruments, which analysers may be polarisers (see Anderton's patent above mentioned), corresponding in their effect with the effect of the polarisers in the lantern, or they may be hand screens so tinted as to correspond in their effect with the effect of the tinted screens in the lantern; or they may be some other kind of instrument to correspond with another kind of differentiation in the lantern. The effect of the analysers or corresponding instruments will be to convey the separate images differentially to the separate eyes, so that the data for a stereoscopic image will be presented.

Instead of superimposing the double, triple, &c. images on the screen, I may project them side by side upon the screen or otherwise, and, instead of using a hand instrument which will analyse two or more images superimposed on the screen, I may use instruments which will analyse images projected adjacently on the screen.

It may here be remarked that the slides prepared as above explained may, if desired, be passed through a kinetoscope, and viewed with stereoscopic glasses therein, in lieu of projecting the pictures on a screen.

This arrangement, however, is not suitable where a company is assembled for viewing the pictures.

## THE BIOGRAPH IN THE VATICAN.

UPON the announcement of the recent illness of Pope Leo XIII., it was found that with one exception no authentic photograph of the Pope had been taken during the past six years. Within a few months, however, no less than 17,000 photographs of the Pope have been taken with his sanction. These photographs were taken in the loggia and gardens of the Vatican with the aid of the Biograph camera.

Mr. William Kennedy-Laurie Dickson, representing the Mutoscope and Biograph Syndicate, Limited, of London, England (the English connexion

of the American Mutoscope Company), went to Rome for the purpose of obtaining moving photographs of the Pope. He had credentials from Cardinal Gibbons, Monsignor Martinelli, Archbishop Ireland, and other noted prelates in the United States, and by special permission of the Pope he secured nine series for the Biograph and Mutoscope, and these scenes were exhibited on December 14, at Carnegie Music Hall, New York City, in the presence of Archbishop Corrigan and other distinguished clergymen of the Roman Catholic faith. They had previously been shown to Monsignor Martinelli in Washington, and given his approval.

The moving views, says the *Scientific American*, show the Holy Father walking and riding in his carriage and sedan chair about the halls and gardens of the Vatican, and in some of these scenes the Pope is seen bestowing his blessing upon the bystanders. He is also seen walking about the garden and sitting on a rustic bench surrounded by some of the chief members of his official household and the Garde Nobili. The views certainly bring us into a more intimate relation with one of the great figures of the closing years of the nineteenth century. When Mr. Dickson was taking the photographs, the Pope asked for an explanation of the apparatus. A copy of the *Scientific American* containing an article on the American Mutoscope and Biograph, published on April 17, 1897, was shown him. His Holiness became much interested in the paper.

The laboratory of the International Mutoscope and Biograph Syndicate, where all of the moving-picture apparatus is developed and prepared for the market, is at Canastota, New York. At this laboratory there are employed a large force of inventors and mechanical experts under the direction of Messrs. Marvin & Casler, and constant efforts are being made to develop new and improved forms of moving-picture apparatus, and to discover new methods of taking and exhibiting moving-picture views. All the intricate and special machinery involved in the process of reproducing these views with marvellous exactness is designed and built at this laboratory, and this work requires great mechanical skill and the most perfect tools and appliances known to the mechanical art. The accuracy of this class of apparatus will be better appreciated when one considers the enormous magnification at which these views are projected upon the screen, and the rapidity with which successive views must follow each other in perfect registration. Imagine a sequence of two thousand pictures, each two inches by two and a half inches in size, following each other in turn through the projecting lantern of the Biograph every minute, each picture being magnified on the screen to a size of twenty by twenty-five feet, and think how perfect must be the registration of each surrounding picture in order that the result of the image upon the screen may not appear to dance about and vibrate, but may appear as one continuous set picture! Not only is precision in projection required, but also in the printing of the positives from the original negative. The negative prints taken by the original camera do not always follow each other at equal distances upon the strip of film; consequently, in printing the positives, the printing machine must be able to correct this imperfect spacing and produce a band of positive prints printed perfectly equidistant. The printing machine must also be able to properly register and print bromide pictures from the same negatives, but these pictures on a band of bromide for the Mutoscope have to be spaced much wider than when printed on celluloid strips for the Biograph. The printing machines are arranged to run entirely automatically, and so perfect is their design, that, if for any reason a print does not register perfectly, the operation of the machine stops and a bell is rung, warning the attendant that his attention is needed. The apparatus constructed at the laboratory is sent out to the various Mutoscope companies in England, Germany, France, and Holland, and any ideas in moving pictures developed by any of these companies are at once forwarded to the American laboratory for perfection and trial.

## MOVING PHOTOGRAPHY FOR THE MILLION:—ALL ABOUT THE BIRTAC.

THE Croydon Camera Club was fortunate enough, on Wednesday, 25th, ult. to enjoy a demonstration lecture by Mr. Birt Acres on 'How to make a moving photo for 2s. 6d.,' which drew an audience of over forty.

The President having sketched Mr. Birt Acres' cinematographic achievements, the latter proceeded with his exposition, in the course of which he explained, from beginning to end, exactly what has to be done by the amateur who desires to take up this fascinating branch of photography, and further pointed out how the mechanism and other devices of the admirably designed little "Birtac" enable photographic film negatives to be taken, and, after printing, how the same instrument is used for projecting the moving photograph upon the screen. Not the least remarkable part of the subject is that, although each film costs but 2s. 6d., the picture on the screen runs as long as the average films shown by the more expensive cinematographs. Moreover, although each of the film positives is only a quarter of the usual area, it gives a picture on the screen which is full of sharpness and definition, and measures 4 feet in diameter.

It is impossible to follow Mr. Birt Acres through all his technical details, enough that he took this opportunity of publicly exhibiting and explaining for the first time two new inventions.

The first was one which permits the operator to show enough film to run for a quarter of an hour or so without the usual tedious changing interval. The second is an ingenious and effective device applied to the Welsbach burner, which should possess an interest beyond its applicability to cinematography. The invention is one whereby gas, drawn from the house supply, instead of passing through the burner at the ordinary pressure, is made to do so at a higher pressure. The difference in light intensity produced by Mr. Birt Acres' simple yet effective attachment was shown by first using the ordinary pressure with a Welsbach burner, and then applying the increased pressure, when the apparent brilliancy at once vastly increased.

#### THE BIRTAC IN ACTION.

Having thoroughly explained the initial procedures, we were next shown the "Birtac" in use as a projector of the moving pictures. Although the light was only what is produced by the smallest Welsbach mantle (1½ in.), and the pictures were shown through a clouded atmosphere on the large scale of 5 feet, the illumination was much better than could be imagined. For ordinary purposes, in dwelling-rooms, &c., providing a stronger illuminant be not used, a 2 feet 6 inches picture would be amply large enough, and would be illuminated to full brilliancy. There was a noticeable reduction of the often unpleasant flicker which accompanies moving photographs; the machine worked easily, without hitch, and without the excessive noise of many another machine. Altogether, the general opinion was that not only was the instrument a remarkably cheap production, but that it was not less notable for its compactness, efficiency, and finish.

The President, in proffering the meeting's thanks, suggested that Mr. Birt Acres should pay them a return visit that day twelve months, when he hoped several of their members would entertain Mr. Acres with a brilliant display of moving photographs taken by themselves with the "Birtac," and jocosely proceeded, amidst loud laughter, to hope that they would be able by that time to give Mr. Acres a striking object-lesson on "How to use his own invention."

#### THE HOLE IN THE WALL AND PUZZLED PRINCE.

In acknowledging the compliment, which was vociferously paid by the audience, Mr. Birt Acres, who was in rare anecdotal vein, much amused his auditors by relating how he had been asked to photograph the arrival of H.R.H. the Prince of Wales to open the Cardiff Photographic Exhibition. Shown where the ceremony was to be held, he said it was impossible to cinematograph the function, "for it would necessitate knocking a hole in the wall." To his surprise the Exhibition Committee immediately ordered the wall to be partly demolished! Subsequently the moving picture was, by special command, shown before eighty guests—half of whom were princes and princesses—at Marlborough House, when all at once the whole assemblage burst into hearty laughter. He (Mr. Birt Acres) could not imagine what could be the reason. However, the Duke of York, with sailor-like impetuosity, exclaimed, "We must have that again!" And they did. On the second time of showing it, Mr. Birt Acres kept his eye on the scene, and when he saw H.R.H. step from the carriage, and, consequent possibly on the cinematograph being at work, pause for a moment in doubt, push aside his hat, and seek with hand for inspiration amongst the locks of his head, the Royal amusement was explained.

Sir David Solomons, Bart., his Worship the Mayor (Mr. G. J. Allen), Mr. F. H. Pearce, and Mr. H. J. Barclay were elected members.

By making use of the exceedingly low temperatures that can now be obtained, a very simple method for exhausting X-ray and other vacuum tubes presents itself. An example of this was given by Professor Dewar at a recent meeting of the Royal Society, at which he was able to produce an almost perfect vacuum. By dipping the end of a closed tube filled with air into liquid hydrogen, the air quickly condensed at the bottom in a solid form. It then only remained to separate from the rest that part of the tube from which the air had been so removed, by heating and sealing off, and the tube was found to possess an extremely high vacuum. In fact, so perfect was the vacuum that it was difficult to pass an electric current through it. One great advantage of this mode of procedure is that in the above case only one minute was taken to obtain the required result.

THE "GREEN RAY."—The "green ray," an optical phenomenon which has been made the foundation of a story by Jules Verne, is a flash of greenish light seen as the limb of the sun rises or sets under certain conditions of the atmosphere. The sea horizon is good for observing it, but the effect is occasionally seen in the Alps or other mountains, and according to Plot Bey, in a paper to the Académie des Sciences, Paris, it is often to be observed in Egypt, from the point of the Delta to Alexandria or Suez, both at rise or set of sun. The ray is distinctly visible, and always of an emerald green, brighter as a rule at sunrise than sunset. At sunset, when the eye can follow the effect better, the ray sometimes appears longer, and ultimately takes a blue tinge. The blue ray has also been observed preceding the green ray at sunrise, for example, by Mr. William Giff, near the ruins of Memphis, not far from the stepped pyramid of Saggarah. He even thinks the ancient Egyptians were familiar with it, because in monuments of the fifth dynasty and others the sign "Kha," representing the rising sun, has the outer streak of a

blue colour, and the two inner streaks are green. Their writings also speak of the greenness of the sun on rising, and they liken it to an emerald. It is evident from all this that the "green ray" is an objective, not a subjective, phenomenon, and that the horizon of the sea has nothing to do with it. Nevertheless, the state of the atmosphere evidently has to do with it, and that of Egypt, ordinarily pure, seems to have much, for the ray is seldom seen elsewhere on land.—*Invention.*

Who was the first to discover the electric light? Our belief up to the present has been that it was Sir Humphry Davy, in 1813, but it now appears that it was Vassili Petroff, a Russian professor, who accomplished the deed in 1802. This is what we read in a note in the Russian edition of the *Cours d'Electricité*, by Eric Gérard, which has been inserted by the translator, M. A. Chatelet, who calls it an historic rectification. Almost all the electrical books published on the Continent tell us that Sir Humphry Davy discovered the electric light in 1813, and no one will hesitate in acknowledging that Russia is rather slow in recognising the services of her scientists, since it took her not less than ninety-six years to become aware of the existence of the 2400-cell battery which allowed Petroff to strike the electric arc before Sir Humphry Davy.

CALCIUM CARBIDE IN NEW YORK CITY.—The Fire Commissioner of New York City has taken steps to regulate the trade in calcium carbide. Owing to the fact that this substance is now stored in most of the sporting goods houses and bicycle stores in the city, it has seemed necessary to take some steps regarding the matter, as the gas is generated by coming in contact with water, and it will readily be seen that it might cause a disastrous explosion, if kept in considerable quantities, in case of a fire. According to the new rules, all calcium carbide in transit through the city and in storage must be in hermetically sealed iron receptacles and marked plainly "calcium carbide—dangerous if not kept dry." No single package must exceed 100 pounds. As to the sale of the carbide, not more than twenty pounds, either in bulk or in cartridges, can be stored or kept in any building used for a dwelling or mercantile purpose, and this amount can only be kept on a permit obtained from the Fire Department. This permit will provide that quantities in cases of two pounds shall be in tight metal packages and kept elevated at least six inches from the floor in a fireproof safe above the street grade. The manufacture, transportation, storage, selling, or use, of liquefied acetylene is absolutely prohibited within the city limits. Provision is made for the storage of calcium carbide in sealed receptacles in quantities not exceeding 100 pounds in isolated buildings of fireproof construction. The storage must also be with a permit from the Fire Department, and the entire quantity stored must not exceed 500 pounds in the aggregate.

LEEDS PHOTOGRAPHIC SOCIETY.—January 24, Mr. Godfrey Bingley (the President) in the chair. Mr. Percy Lund, of Bradford, was the lecturer, "In Wordsworth's Country." Mr. Lund proved a very able exponent of the district traversed. He gave his hearers an outline of the life of the great poet and the surrounding country of his home, illustrated with about forty pictorial photographs of Grassmere, Rydal Water, &c. The lecturer said that he had a purpose in view when he commenced with his camera and note-book to characterise the work of William Wordsworth, and endeavour by the aid of photography to do something more than merely take views topographical of the district. His object was well carried out, and the audience testified their warm appreciation of the pleasure afforded them. The Chairman subsequently announced that the Annual Dinner in connexion with the Society would be held at the Albion Hotel, Briggate, on February 10, and that Mr. H. B. Buckley would lecture upon "Instantaneous Photography" on February 14.

HACKNEY PHOTOGRAPHIC SOCIETY.—January 24, the President (Mr. E. Puttock) in the chair. The feature of the evening was an exhibition of very fine lantern slides by Mr. J. Gunston, illustrating a trip to Switzerland. The collection included a fine series of views of the Valaisian Alps in the neighbourhood of Zermatt, and their interest was much enhanced by Mr. Gunston's description of the places illustrated. Examples of Messrs. Burroughs & Wellcome's new toning tabloids—sodium formate—were distributed for trial, it being understood that the results should be brought up on February 7, when a representative of the makers would be present. It was announced that the coming season's excursion programme was in course of being compiled, and suggestions as to suitable places for outings were invited.

At the meeting of the Institution of Civil Engineers, on January 17, Professor W. C. Roberts Austen, K.C.B., F.R.S., gave a statement of the principles which guide the micro-photography of steel rails. The most generally useful information as to the structure of a steel rail is obtained by treating a highly polished surface of the section with an effusion of liquorice in water, which stains the pearlite a dark tint and leaves the ferrite unacted upon. The most convenient magnification is between 100 and 150 diameters. Normal rails have thus been shown to consist of patches of pearlite set in ferrite; and, although the structure is common to all rails, the ratios of the areas differ widely, the amount of carbon increasing with the area of the pearlite. If the ferrite is arranged in large enclosed polyhedrons, the temperature to which the rail was raised before rolling was too high. The strength and insensibility increase as the size of the grain diminishes; and closely interlocking ferrite and pearlite represent the condition which most favours the prolongation of the life of the rail.

### LANTERN MEMS.

WHY will some lecturers still use transparent screens when they could employ opaque ones to far greater advantage? The fallacy of having the lantern behind the screen was forcibly brought home to me, and those of the audience sitting near me, at the lecture by Mr. Savage Landor, on "Tibet," at the St. James's Hall. The majority of the photographs shown were really beautiful, but, as pictures, were completely spoilt by the strong flare of light inseparable from a powerful illuminant, and coming, as it often did, in the most interesting part of the picture, or where the effect of light and shade was best. This was particularly noticeable with some of the mountain scenes.

\* \* \* \* \*

WHY the lecturer or operator decided to have his lantern behind the screen I cannot imagine, for there was plenty of room in front to place the apparatus, unless it was another County Council regulation that prevented them taking up a position in the centre of the hall, and the focus of the front lens not being sufficiently long for the lantern to be placed under the gallery, as in previous lantern displays, when views and cinematograph films were projected on an opaque screen, or a linen one used as such. I remember that Dr. Nansen's pictures were shown by a lantern from the gallery, and very successfully too, but the focus of the front lens then employed was something like twenty inches.

\* \* \* \* \*

I do not in the ordinary way advocate such long-focus lenses, but specially large halls require special apparatus, and a lecturer who caters for large audiences should be prepared with a suitable lantern and lenses of such a focus that he can adapt his position to the construction of the hall. In fact, a battery of lenses is a necessity of the modern lantern equipment, in order to avoid such results as I have alluded to above, and which are unpleasant to the eye, especially when the lantern happens to be on about the same level as the seats, which was the case of those in the balcony. At another lantern display, that of one of the large music halls, where some photographs of Klondyke were being shown, the same kind of flare was visible, but, as I was then seated below the level of the arc lamp, the bright spot came generally in a part that was not of such importance to the picture; but, nevertheless, it was marred in consequence.

It is time that all large halls were provided with suitable roll-up opaque screens for projecting lantern slides on, for it is not reasonable to expect a lecturer to carry about a fifteen feet square or larger screen with him, and the results given by the white distempered screens are far in advance of those obtained where views are projected on a folding-up linen screen. If lecturers were to stipulate that a screen of this order should be provided by the management, it would soon be an accomplished fact, for such men as Dr. Nansen, Sir Robert Ball, Professor Lewis, Mr. Savage Landor, and others that will occur to my readers, can practically dictate their conditions, and all lecturers that followed would benefit by the new order of things.

\* \* \* \* \*

THE mention of Professor Lewis's name reminds me of his excellent Cantor lectures at the Society of Arts and the practical information he gave his audience in regard to the manufacture and use of acetylene gas. One point stands out strongly among so much that was of value, and that is, the simple fact of adding sugar to the water used for the decomposition of the calcic carbide made the generation of the gas most regular. All that is necessary is to make a saturated solution of sugar and use that instead of the ordinary water. Another matter as to purity of carbide, and, in consequence, the superiority of illumination obtained from the gas: Given pure carbide and an ideal generator, the amount of gas given off per pound of carbide should be five cubic feet, but not two in twenty gave this, in fact generally the amount from generators on the market was three and a half cubic feet per pound.

\* \* \* \* \*

As regards safety in use, the first thing to do is to drive off all air from the generator, for with one part of acetylene and one part of air in an enclosed vessel provides the most explosive mixture. Previously it was thought that the range of explosive mixtures was a small one, but the Professor stated that it was shown by recent researches nine volumes of air and one of acetylene was an explosive mixture, while between eleven and twelve parts of air and one of acetylene gave the maximum explosive mixture, and as much as seventeen parts of air to one of acetylene was found to be explosive under certain conditions.

\* \* \* \* \*

THOSE using generators may know by the residue of the calcic carbide if their apparatus is working satisfactorily, for it tells the tale of the temperature during work, and that apparatus which works at a moderate temperature is most suited for the purpose. If the deposit of lime is *white*, a temperature of 400° Centigrade has been reached during decomposition; if *yellow*, then 600° to 700° Centigrade; and, if *black*, over 780° Centigrade is the heat to which the carbide has been subjected. In some instances it has been known for the carbide to be red-hot in the generator, and it is simply marvellous how water can raise the temperature of any substance in the rapid manner it does with calcic carbide, hence the necessity for slow generation.

IN theory, half a pint of water is sufficient for one pound of carbide; but, in practice, one pint per pound is necessary to make up for water vapourised as steam, and by water clinging to the lime. It is necessary that the carbide should be pure, and it is satisfactory to know the British-produced carbide is wonderfully free from impurities. There is no doubt that there is a great future for acetylene gaslight, and, when it is fully understood and apparatus placed on the market that as nearly as possible approaches the ideal, then not only lanternists, but the general public, especially in country places, will be able to avail themselves of this truly marvellous light.

ANOTHER new light has been invented of an incandescent electric order that bids fair to revolutionise general lighting, for, while possessing the pleasantness of the glow electric lamp, it will have a far longer life than the delicate carbon filament as now used in incandescent electric light lamps. The new lamp, as described by Mr. Swinburne at the Society of Arts, is the invention of Professor Nernst, of Göttingen University, and, while employing rare earths as used in the Welsbach mantles for incandescent gas lighting, has the advantage of a fairly strong rod form instead of the delicate fabric now so familiar. The curious part is, that these earths, which in the ordinary way are insulators or non-conductors of electricity under normal conditions, are good conductors when heated; hence, by the simple device of warming by a match or small spirit lamp, the rods are raised in temperature and the electric current passes through them and renders them incandescent. It is hoped shortly to have some experiments with these lamps as lantern illuminants.

G. R. BAKER.

## COLOURING LANTERN SLIDES.

### II.

IN a previous article reference was made to the necessity of absolutely clear high lights being present in the slides intended for colouring. A beginner having provided himself with a suitable subject, such, for instance as a church or any building standing in the midst of a landscape in which a fair amount of trees are included in the foreground, and middle distance with well-defined hills in the background, may proceed to make preparations for conducting the work in a comfortable manner at any well-lighted window, and to do this a good retouching desk is necessary.

The following tubes of ordinary artists' oil colours should be provided; these will cost about fourpence each, viz., Prussian blue, burnt sienna, raw sienna, gamboge, crimson lake, and ivory black, together with a tube of megilp and a small bottle of mastic varnish, and a supply of spirits of turpentine. With these at hand and a few good finely pointed sable brushes, a very wide range of work can be done.

In colouring a lantern slide it but seldom happens, when dealing with such an example as has been chosen, viz., a landscape, that much actual brush work is required. The operation, in point of fact, is more of dabbing, and this is by far the most important part of the entire operation, and will take some little practice for any one to become proficient in. After a few attempts, however, the dabbing will become quite a simple matter, and great rapidity in the laying on of broad patches of colour in an absolutely even manner will be easily acquired.

Having carefully studied the nature of the picture to be coloured, when such is placed upon the retouching desk, the first portion which falls to be worked upon is the sky. If attention has been paid to the foregoing remarks in these articles, this will be of absolutely clear glass in the slide, or as clear as gelatine can be made to yield such. If it be desired to so colour the sky portion of the picture as to resemble a sunset, then the first act will be to commence by placing a few streaks of Prussian blue, previously amalgamated with a little megilp along the upper portion of the sky, care being taken, however, that the colour is not applied straight across in parallel bands, but more in an oblique direction, dropping somewhat from either of the top corners according to the formation of the picture.

The Prussian blue has now to be dabbed in an even sheet over the surface desired by means of the ball of the middle or forefinger, the dabbing being so conducted as will distribute the colour more densely at the zenith than at its lower extremity, at which point it must be very faint, merely, as it were, vanishing into clear glass at those parts where the warmer tints of the sunset hues are to be worked in.

At first this dabbing operation may appear difficult, but it will imperceptibly become easier after every attempt towards success, and a beautifully even gradation from dense blue at the zenith to a very slight blue tinge where it joins the warmer hues, always noticeable in a sunset scene, will be one of the easiest tasks in the whole operation. The

Prussian blue, having been evenly distributed by means of dabbing the lower portions of the sky, has now to be dealt with, small streaks of crimson lake amalgamated with a very small portion of Megilp is now placed in position, a small distance below the point where the blue colour has been shaded off. The ball of the finger used in dabbing is now cleaned with a rag and turpentine (this may be kept at hand in an old egg cup). With the clean finger the crimson lake is dabbed until it is blended nicely into the blue and overlaps the hills in the background. When the crimson lake has likewise been evenly distributed, any overlapping on the hills or other portions, such as the tops of trees, is wiped clean with a rag, leaving a faint line of clear glass just over the hill tops; this faint streak of clear glass is then treated delicately with a slight golden glow, likewise produced by dabbing a very little gamboge, in the same manner as the two previous colours, any overlapping of the hills being wiped off with a clean rag. We have now a plain tinted sky, verging from golden yellow at the horizon to a somewhat deepish blue at the zenith, and, if the dabbing has been skilfully performed, the sky portion of the slide will present a nice even appearance free from any small finger markings or other eyesores.

A beginner, however, at lantern slide colouring is very apt at this stage of the operation, when comparing his handiwork with that of the professional colourist's, to lose heart at the appearance his slides will present alongside that of a trade slide, and very naturally jump to the conclusion that there is some other way of doing the work, whereby the slide is made to present the delightfully even and brilliantly transparent sparkle of a professionally coloured slide, but the somewhat crude, hazy, or foggy appearance a slide presents at this initial stage of the dabbing is just what it ought to be, for the misty oily appearance will disappear at the later stages of the operation, so that no one ought to lose heart at seeing the appearance of the slide at this stage, but just go on with the work, concentrating all his thoughts in being able to overcome the dabbing difficulties until a beautifully even surface of colour is laid on. The final transparent brilliancy is acquired later on, which will be described.

Having filled in a warm sunset sky, if it be desired to introduce a very few fleecy clouds, the services of a finely pointed stump are brought into play. Nothing makes a better stump for this purpose than the handle of an ordinary paint brush; this may have a piece of clean chamois leather tied on when required. With this stump the shapes of ordinary light fleecy clouds are drawn in upon the flatted sky, and the ball of the finger is again taken to the clouds where necessary, using a little grey colour where such is required in effects that are introduced up against the light.

Having completed the sky portion, attention may now be bestowed upon the hills. After cleaning the tops of them from any overlapping of the gamboge used in working up the sky, if it be desired to introduce a purple hue, this tint is easily produced by mixing in proper proportions a small quantity of Prussian blue and crimson lake, both colours being well thinned with megilp; the purple colour is then in this case applied to the hills by means of a fine brush in such a manner as not to overlap the golden sky line, and if any broad patches have to be introduced dabbing may be resorted to, but as a general rule such surfaces are but of small extent and the brush is made easily to lay on the tint, which in this case is a thinnish wash.

Next in order will most likely come the trees. These will very probably have overlapped the sky line, and, as it is a summer scene we are engaged upon, a good transparent green is produced by mixing gamboge and Prussian blue, working the green colour carefully over the outline of the tree by means of a fine brush.

Any buildings on the view are easily tinted with a little raw sienna thinned with mastic varnish or megilp, and the foreground, if composed of tufted grass, is easily tinted with a similar pigment to that used in colouring the trees, only care should be observed not to apply the colour too strongly, as such tends to give the slide a heavy, crude effect. This must be carefully studied through every portion of the work, and it is just here that beginners are prone to err. What may be termed a light wash or application of colour is generally sufficient.

Pathways may be tinted either with burnt sienna, or, if of a pebbly character, a slight wash of purple tint will probably give the most pleasing effect.

Any heavy objects in the foreground, such as trees, are easily tinted with raw or burnt sienna, likewise heavy masses of rock or masonry. In the latter instances a slight touch of green in the darkest portions will give a mossy effect that is very pleasing. It is in the introduction of these little artistic touches that the great secret of success lies. A beginner by this time will very probably have found out that some of the colours mentioned are more transparent than others. Prussian blue stands unrivalled as a blue in this respect, hence its great value in sky working, and is also invaluable in producing other tints, such as greens, purples, &c. When mixed with red or yellow, such as crimson, lake, or gamboge, the latter colour is also a very valuable one, and is, perhaps on account of its wonderful golden transparency, the most useful in any colour selection; crimson lake is also valuable on account of the difficulty of securing a transparent red.

Burnt and raw sienna fulfil their different functions admirably in being slightly less transparent when used on more opaque parts of the picture.

Not only does the question of transparency form an important item in the selection of colours, there is also the further question of employing

only such as are what is termed good dabbers, as well as those that are amenable to rapid drying. It will not be long ere a beginner will be able to distinguish between what is a good and a bad or indifferent dabbing colour. In the front rank in this respect comes our old friend Prussian blue, than which there is no finer or more useful blue in existence for this class of work.

By the time a beginner has worked in by means of dabbing his first sky, it is very likely he will have formed a pretty decided opinion upon the need of selecting, especially for slide colouring, only those transparencies that are absolutely flawless in those portions which must appear throughout with an absolutely flat and even field. An example of such parts is found in the broad exposure of sky in a landscape slide. Any scratch or indent in the gelatine surface of the slide will soon become apparent in a marked manner owing to the pigment appearing much more opaque at such places, this, of course, being due to the extra quantity of colour held in suspension within the scratch. A mark of this description is fatal to first-class results in a sky line or other equally clear parts of a slide, but is, of course, of much less importance if present in such other parts as are represented with greater depths of opacities.

It follows, therefore, that all imperfect slides should be discarded for colouring, and attention strictly to this point will soon become marked in the superior class of pictures a worker will turn out. It is far better to devote a little attention to the production of a really perfect surface to all slides intended for colouring purposes than to attempt to patch up or produce good results upon such slides as are full of imperfection and quite unsuitable for this purpose.

T. N. ARMSTRONG.

### MY LANTERN EVENING IN THE FENS.

THE article on "Judging a Lantern-slide Competition," in the February issue of *THE LANTERN RECORD*, reminds me very much of a lantern show I gave a few weeks ago to an audience of rustics, who had assembled in the large club-room of a village inn, situated in the very centre of the fen district. How it all came about is interesting.

Two winters ago, many young men of the village formed a mutual improvement society, at which papers were read, debates held, &c. The meetings were held weekly during the season, and a very substantial balance was in hand. At the beginning of this last winter, however, the young men thought it selfish to take their pleasures alone, and accordingly invited the opposite sex. This progressive movement did not suit the President, who was also the vicar, and a ballot was taken, with the result that forty voted for the admittance of ladies, and three against. One of the minority was, of course, the vicar, who, seeing that the young men were determined to include females, smashed up the society. The young men of the village now spend their evenings playing draughts, chess, and sing-songs, at the very respectable and well-managed inn.

When the society was in a flourishing condition I had promised a lantern evening, in fact the date was fixed and all my own arrangements made. After the smash I saw the secretary, who was, of course, full of regrets, &c.; nevertheless, he asked if I, so as not to disappoint some of the members, would give a show at the village inn, as the use of the only other large room in the village (the schoolroom) had been refused by the vicar. During the course of our conversation I began to see that a few of the members wanted to try and upset the late president by having a show at the village inn, a place, strange to say, he never visited. I entered into the spirit of the thing, and promised a show free of expense if they would find the room. I did so because I had in my head an experiment that I had long wanted to work out, and now was a grand opportunity. Before detailing the experiment, I might mention that the ex-officials of the society obtained the use of the club-room in the village inn free of charge, on one condition, *i.e.*, an interval of a quarter of an hour was to be allowed for refreshments, and the finish to be about ten minutes before closing time. I consented to this, and I heard afterwards that the landlord made a good thing out of it. But enough of this, get we to the eventful evening. My private lantern shows are not large, and I have never yet found that I really needed a limelight outfit. I had always used oil up to the lecture I am now describing, but for that evening I bought one of Tylar's Aladdin acetylene lamps, and, thanks to its efficiency, ease of management, and freedom from smell, the illumination of the six-foot screen was perfect, and the whole proceedings went off without a hitch. I shall never again use oil if I can get calcium. Gas was unknown in the village, which fact accounted for the extra special interest taken in my charging the lamp and making the gas, all of which I did in full view of the audience. Hitherto evil-smelling oil lamps had been used, and the sensation that I caused may be better imagined than described.

Punctually, at seven o'clock, the doors of the large room were thrown open, and in rushed such an audience the like that I had never before witnessed. No charge was made, every one was welcome; there were old and young, tradesmen and labourers, teetotalers and tipplers, in Sunday and working attire. A limited number of children were admitted, for the simple reason that they would have filled the room, which, by the way, held about 150 persons. So much for the arrangements and audience. The most important part was yet to come. I was to try the experiment that I had long thought of, *i.e.*, to solve the question, "What

slides are most appreciated by an audience of rustics?" I divided my collection into ten parts, *viz.*: (1) Local views and celebrities; (2) Views of London; (3) General foreign views; (4) Statuary and studies of the nude; (5) Figure studies; (6) Astronomical and micros.; (7) X Rays; (8) Actresses; (9) Ordinary highly coloured commercial slides—religious and tales; (10) Comic slipping slides.

A selection from the many remarks made during the evening would prove very amusing reading, but space and time now forbid their insertion in this article. I explained the slides as I passed them through, and at the end of the show took votes on which were the favourite subjects. All were allowed to vote, two or more times should they so desire, and the result was as follows:—Seventy-four voted for section 1 (local views), which included various views of the church, portraits of the publican, barmaid, policeman, &c., which I had taken specially for the occasion. The portrait of the policeman was hailed with a tremendous outburst of cheering, he being a very popular man in the village. One of the younger generation caused much amusement by saying, that he (the policeman) "did not stand like that—so still—when he saw boys in an orchard." The views of the church, in spite of the trouble with the vicar, came in for much applause. The next on the poll was section 7 (X rays), seventy-two voting for it. Green as these rustics are said to be, they were greatly interested in the marvellous X-ray pictures, that were taken, and kindly lent to me, by Mr. W. H. Hayles, of Cambridge. They sat, open-mouthed, as I passed before them pictures showing shots and needles in the hand, enlarged joints, &c. Section 8 was next, with seventy voters. My audience were greatly pleased at many of the charming faces I put before them; little thought they that much was due to retouching the negative and painting the model. Owing to some rather rude remarks against section 4, and for which fifty-seven voted, I was compelled to cut down the number of slides; what few I did exhibit, however, pleased about one-third of my audience. Fifty hands were held up for section 6, they being most fascinated by photographs of the moon, and of a common every-day flea. The slides representing figure studies elicited forty-four votes; those of London (section 2), thirty-four votes; general foreign views (from a missionary set) obtained but twenty hands. The last two on the list were also last on the poll—commercially coloured and hand-painted slides, and comic slipping, these obtaining twelve and nineteen votes respectively.

I do not claim that my little experiment has produced anything of value, as audiences, like slides and lecturers, differ greatly. It is, however, interesting to note that photographic slides were first favourites, and that the coloured slides had but few admirers, and of these few the majority were children, who, of course, are more interested in a man swallowing rats than, say, a fly's tongue.

It, perhaps, is not strange that local pictures should head the poll, for, although the originals were seen by the natives almost every day of their lives, the novelty of having them reproduced on the screen caused the intense enthusiasm and the heavy voting.

RICHARD PENTLACE.

### NERNST'S ELECTRIC LIGHT.

[A paper read before the Society of Arts by Mr. James Swinburne.]

BEFORE describing Nernst's invention it may be profitable to spend a few minutes reviewing the position of electric lighting. The whole industry is at present controlled by the incandescent lamp. We are so accustomed to this, and it is taken for granted in such an unconscious way, that we do not realise how much everything depends on the maker of the carbon incandescent lamp.

#### HISTORICAL NOTES.

In very early days, that is to say, in the early eighties, there were a few Edison lamps at 100 volts, with an efficiency too horrible to mention, but the Swan lamp came along made for 50 volts. I say made for 50 volts advisedly; I mean that the makers tried to make 50-volt lamps, and produced lamp taking from 40 to 60 volts. If the lamps were not bright enough, you ran the engine faster, or put a smaller pulley on the dynamo. (The belt then generally slipped, but that is not to the point.) For about four years, which is a long period in the development of such a rapidly growing industry as electrical engineering, the makers of incandescent lamps, or, in fact, the makers of the Swan lamp, decreed that the electro-motive force used should be from 40 to 60 volts. There was no appeal. There was no development of central station supply at that time, but still, even then, in large buildings there was the longing for higher pressures on account of the cost of the mains.

About 1885, the Swan 100-volt lamp came into use. It was a clumsy affair, with little loops of platinum at the sides. At first the lamps were pretty bad, but they gradually improved, and 100 volts, or in some cases 110 volts, became the recognised pressure for electrical supply.

As town lighting from central stations came into being, the limit of 100 volts became a serious trouble, and the evil was partly mitigated by the use of three, or even five, wire systems. I must point out that the incandescent lamp exercises its tyranny in two ways. It not only insists on a low pressure, such as, say, 100, and thus demands large leads to feed it, but it is so sensitive to variations of pressure that the system of distribution has to be arranged to give a practically uniform pressure at the terminal of the lamp. The necessity for uniform pressure

probably gives more trouble, and costs more than the mere low pressure, and it would be cheaper to supply at 100 volts with a good margin of permissible variation of pressure than supply at 200, with a very small percentage of variation.

Quite lately the incandescent-lamp makers have produced things called 200-volt lamps, and some make them for 250 volts. So there is a general tendency on the part of supply companies to jump to a 200-volt supply. The innocent consumer is therefore pressed by the company to change over to 200 volts. The company likes the change very much, and the lamp-maker also enjoys it, as he makes more lamps and charges more for them.

Considering the enormous importance of the incandescent lamp, its improvement has received extraordinarily little attention. It limits us as regards pressure, it used to hamper us by its cost, it limits us as to variation of pressure, and it limits us very seriously by its inefficiency. Yet, in spite of these, the carbon incandescent lamp has made practically no advance in fifteen years. Of course, mere detail improvement in manufacture has taken place, and this has led to better quality and greater uniformity, hence cheapness; but there has been no radical improvement. The jump to 200 volts from 100, or from 50 to 100, did not depend on any sort of radical improvement in the incandescent lamp; it was merely the result of detail improvements, making it possible to produce long thin filaments. Other things being equal, it is easy to see that the long thin filaments must be weaker. If the carbon has the same specific resistance, the relation between pressure and length is  $E = L\frac{1}{2}$ , and  $E = D - \frac{1}{2}$ . If the filaments are flashed, the proportions will be still more extreme. The question of high-pressure incandescent lamps is thus: how far can we make the filaments longer, and thinner, and flimsier without exasperating our consumers? Unfortunately the consumer is rapidly getting saddened as it is. The 100-volt eight candle-power lamp does not please him much, and the 200-volt 8 candle-power lamp has in no way delighted him; if the lamp is made with two 100-volt filaments in series, it combines the disadvantages of both without the advantages of the small candle power of either. But it adds some further disadvantages peculiar to the higher pressure which I have not so far touched upon, and that is, that the higher the pressure the more troubles there are through the silent discharge, or whatever it is called. I need only refer to the well-known experiment, in which a third terminal is sealed into the lamp. A galvanometer then shows a current going across country inside the lamp. This is, no doubt, intimately connected with the life, or rather with the death of the lamp.

I have dealt with the question of high-pressure incandescent lamps at some length, because the subject is really of vital importance and is too much neglected. Our technical colleges, and our technical press, and our technical societies pay the greatest attention to questions of a per cent. or two in the efficiencies of dynamos and transformers, and give a good deal of attention to engines and boilers. That is because there is plenty of room for calculations in connexion with these subjects, but the incandescent lamp, which at present holds the whole career of the lighting industry in the little curl of flimsy red-hot carbon that can hardly support its own weight, receives no attention at all. How much does the average electrical engineer know about incandescent lamps? The only subject that is treated in the same way is the cable. About half the money in town lighting goes in the cable, a mere fraction in the dynamos and transformers themselves, so the average electrical engineer knows nothing about cables.

So far I have only discussed the incandescent lamp; the arc lamp has also to be considered. I will not say much about the arc lamp just now, but will add a little more when the Nernst lamp is compared with it. The ordinary arc is limited in pressure to about fifty volts, including the series resistances necessary for regulating. The enclosed arc is a new development, which is more satisfactory as regards pressure and as regards consumption of carbon.

The lamp I describe to-night is the invention of Professor Walther Nernst, of the University of Göttingen. Though he is a young man, Professor Nernst's name is already known to all modern chemists as a leading authority and original thinker in the field of physical chemistry. It is unusual for a man who has climbed to the top of one tree to jump to the top of another.

Nernst's, like most great inventions, is exceedingly simple as soon as it is understood. The efficiency of an incandescent body, as far as radiation goes, depends simply on the temperature. The efficiency of an incandescent lamp, for instance, depends on the temperature of the filament only, providing there is no loss by convection. The carbon will not stand a sufficiently high temperature, especially as, in addition to its low specific resistance, the filament has to be long and slender, and thus weak. Nernst, therefore, chose a material that would stand higher temperatures than carbon, and his material has the incidental advantage that its specific resistance is so high that strong rods can be used for high pressures instead of thin filaments. The most refractory materials so far used in lighting are zirconia, which has been used to replace lime in the limelight, and the oxides or so-called rare earths, in the Welsbach mantles. I am aware, of course, that many people suppose that the Welsbach mantle is not very hot, treating it as if it were at a temperature, for instance, below the melting point of platinum. The

light emitted is supposed to be due to some special power of selective emission due to the oxides employed. I have had a good deal to do with incandescent gas mantles, and I find no reason to suppose there is any magic effect of this sort going on. The part of the flame where the mantles hang fuses platinum wire easily, and very few materials can stand the temperature without fusing or volatilising. Lime and many other oxides volatilise slowly from the mantles. I do not mean that the mantles are above the boiling point of lime. I have some idea of its melting point, as I have made a few pounds of melted lime and run it out on the floor to look at it. The Welsbach mantles, which are now chiefly thorium, are at a temperature near their softening point, and in the making are raised to a temperature at which they begin to soften.

Nernst takes highly refractory oxides as his material. It does not seem promising, because such oxides are notoriously good insulators. But such insulators are electrolytes when hot; Nernst, therefore, heats the rods to make them conduct, and then heats them electrically, preserving a temperature which is within the limits that the material can bear without softening. This means that he can take the most refractory bodies supplied by the whole range of chemical research, and can heat them to a temperature short of their softening point, and can thus get an efficiency unknown to workers on the incandescent lamp. Such efficiency also means whiteness of light, so long as the efficiency is not too high. Thus the crater of the arc, being at a temperature of boiling carbon, gives a light that is unpleasantly blue.

The material is worked up into little white rods. Each rod is mounted on two platinum wires, a little paste made of refractory oxides being applied to the joints. The little rod with its two wires is then mounted in a holder which fits ordinary electric-light fittings. As the rods fall in resistance as the temperature increases, after the manner of electrolytes, an increase of current produces a decrease of resistance. This tends to give some instability in running in parallel on supply circuits. This instability is corrected, as in an arc lamp which has analogous properties, due to a different cause, by a series resistance. The Nernst rod has therefore a resistance in series. This is made up of exceedingly fine wire, and for ordinary circuits amounts to ten or twelve per cent. of the whole resistance of the lamp. The consumption, including the resistance, is 1.5 watts per candle for large lamps, and 1.6 for small lights or low pressures. In small or low-pressure lamps the loss of heat at the ends is larger in proportion.

Such a lamp as I have described will not light up of itself, for the rod is an insulator when cold. The simplest way to start it is to warm it up with a match, or, better, with a small spirit lamp. Such a lamp as this is not only very cheap as regards first cost, but very economical in running. The life of rods running at an efficiency of two-thirds of a candle per watt, including the resistance, is already more than 500 hours in good specimens. If the Nernst lamp advances as much in the first few years of its existence as the carbon lamp did between 1880 and 1882, it will soon be made so well that the rods last a life time. When the rod is worn out, a new rod with its wire mounts is all that is replaced. The whole lamp is not thrown away at all.

The method of lighting I have described, though it may be used in many cases, such as large public rooms, is really a savage mode of ignition, fit only for dealing with uncivilised commodities, such as gas and tobacco.

The small lamps and the lamps of medium size are in practice started by a heating resistance. This is arranged close to the rod, and in shunt to it. As soon as the rod is hot enough to conduct, its current works a tiny cut-out in the resistance circuit. In large lamps the heating system is a little more elaborate, as the resistance arrangement is arranged as a sort of hood which covers the rod. As soon as the rod conducts, not only is the resistance circuit broken, but the electro-magnet lifts the little hood clear off the rod. In all these forms the rod and its mounting are replaceable without interfering with the rest of the lamp.

#### THE FUTURE OF THE NERNST LAMP.

Compared with the small incandescent lamps, as you deal with a material of much higher specific resistance, it is easy to give both small lights and high pressures. The question of lighting is exceedingly important, though it appears trifling at first sight. People are so accustomed to lamps being turned on from the door without any further trouble that they will generally object to having to light them with matches or spirit lamps, but there are many cases in which it will be quite satisfactory to have one lamp with an automatic lighter to show you the way into the room, the rest being lighted with matches or a spirit lamp, as needed. There will be, however, a considerable opening for the cheap, small-power, high-efficiency lamp; and the disadvantage as to lighting is small in such cases as cafés, restaurants, churches, hotels, railway stations, and, in short, in most public rooms is small.

Coming now to the next size, that is to say lamps, of 20 to 200 candle-power, and even small lamps in which it is worth while to have automatic ignition, the first cost of such lamps will be higher than the first cost of incandescents; but, as the rod itself has alone to be replaced, that is a matter of very slight importance. This size of Nernst lamp has further every chance of completely ousting the carbon incandescent on the score of cheapness, as to renewals, higher efficiency, better-coloured light, and perhaps more especially high pressures. Once the Nernst lamp becomes

so general that systems of distribution are laid out to suit it, instead of to suit the carbon lamp, the carbon lamp is practically "out of the running." It must be remembered that the Nernst can compete with the carbon filament at any pressure that suits the filament, but the Nernst lamp can easily go right out of the depth of the filament and have the higher pressures to itself. It must be remembered that at present the cost of cables in a system of distribution is an exceedingly large item.

Turning now to the large lamps, they compete with the arc lamp in efficiency. Of course, the efficiency of the arc lamp is not a very definite quantity. The candle power is generally determined by multiplying the current by two and adding zeros at discretion. All I say is that, however many zeros the good nature of the maker may supply, a Nernst lamp taking the same power gives a better light. When carefully arranged on the photometer, the arc may be better in given directions, but a lot of light given in directions that you do not want is not the same as the same light distributed with a uniform spherical emission. The arc lamps shown here will give the audience a good idea of the relative values. The Nernst gives a pleasanter, and, of course, a perfectly steady light. Coming to costs, the Nernst will be very much cheaper in first cost, but enormously cheaper in maintenance. It also goes quite away from the arc as to pressures. There is no trouble, for instance, in making large lamps to work in parallel at 500 volts, and by using double rods at 1000 volts. This puts an entirely new development of electric lighting in the hands of the engineer.

There is one point I have said little about yet. The incandescent lamp, which is still with us, gives trouble, not only because of the low pressure it needs, but also because it demands that the pressure shall be kept uniform. It seems quite possible that the Nernst lamp may be made to stand a much greater variation of pressure than the filament. If this proves true, it means an enormous difference in the designing of distribution mains. I do not like to say much about this yet as the invention is too young, and too little time has been available to make much certain progress in that direction. Results are promising, but it is best not to be sanguine.

It is difficult to discuss an invention like this without being carried away by enthusiasm. I feel, however, that I have but feebly shown forth the probable future of what seems to me the greatest invention in electric lighting that we have seen for many years. Still I am sure I have not been too sanguine.

#### DISCUSSION.

Professor Ayrton, F.R.S., congratulated Professor Nernst on having achieved such a wonderful result by such simple means, viz., rendering an insulator conducting by heating it; and Mr. Swinburne on the way in which he had put the matter before the meeting. The knowledge that an insulator could be made to conduct electricity by heating it was much older than the recent experiments of Sir W. Roberts-Austen, for some twenty-three years ago a paper appeared in the *Transactions of the Royal Society* on that very subject of the extraordinary diminution of resistance in a solid electrolyte by heating. In Japan, plates of zinc and copper were put on each side of a glass plate, which was heated, and the electromotive force passing, as indicated by a high-resistance voltmeter, after short-circuiting the cell, appeared almost as rapidly as if the plates had been immersed in dilute sulphuric acid. It had also been known ever since carbon filament lamps had been on the market that there were certain difficulties connected with them, and many experiments had been made, and patents taken out, with the object of using refractory earths; but, apparently, no one before Professor Nernst had thought of the simple expedient of heating a very good insulator with a match or spirit lamp, applying a current of suitable potential, and thus obtaining a brilliant light, such as they had now seen for the first time. This result was clearly of enormous commercial importance, and would be an entirely new departure in glow-lamp electric lighting. It was also extremely interesting from the purely scientific side, touching on a question which Mr. Swinburne had passed over rather lightly, as if it was only a few foolish people who fancied there was something in the Welsbach mantle which they did not entirely understand. This invention showed, at any rate, that illuminating gas was not necessary for obtaining light by incandescence from the rare earths. Some five or six years ago he asked an assistant of his to look up the literature on the subject of the Welsbach burner, and see if any report had been made throwing any light on the question whether the effect of the burner depended solely on the high temperature. He gave him a reference to a German paper in which experiments were quoted, which seemed to show that the high temperature was not the sole factor. Later on he discussed the matter with a very distinguished English chemist, who agreed in the view that it was not solely a question of temperature, and a year or two afterwards he again discussed it with Professor Elihu Thomson in America, who took exactly the same view. Many people thought that the material of which the mantle was made had the power of absorbing oxygen from the air or the gas, and compressed it, much as spongy black absorbed hydrogen and oxygen, and so caused these gases to burn under considerable molecular pressure. It was not merely that the Bunsen flame raised the material to a high temperature, but that the gas and air were compressed together in the pores of the material, so that the gas

was burnt under pressure, and so you got a much higher temperature than you otherwise would. In the glow lamp, as they were not dealing with gas, it did not seem that the materials could play any such part. There seemed to be something in that idea because it was necessary for the mantle to be a certain exact composition; you could not take thorium or zirconia at random and use it, you must have a certain definite combination to produce an efficient mantle. In fact, it was the addition of 0.4 per cent. of ceria which converted the Welsbach burner from a ghastly failure commercially into a wonderful success. He should like to know whether the mantle was not at a much higher temperature than the flame which surrounded it, and whether a particular combination of materials did not reach a much higher temperature than another combination immersed in the same flame. If so, it was not merely the temperature of the flame which produced the result. There was one great advantage about the Nernst lamp, it did not seem to require a thin glass bell and a vacuum, and thus got rid of a very serious difficulty, because these bulbs were very fragile, and were easily destroyed by a touch of a broom or carelessness in carriage; many lamps also were defective, not from any fault in filament, but because the vacuum was imperfect. He should like to know the reason of the difference in the colour of the light of the Welsbach and the Nernst lamps—was it a difference in material or in temperature? He understood from his colleague, Dr. Armstrong, who visited Professor Nernst some time ago, that it was essential to use an alternating current, as with a direct current the incandescent rod soon ceased to make good contact with one of the platinum terminals.

Mr. Hiram Maxim said he had always understood that the light in the Welsbach burner did not depend entirely on the temperature. There were many things in nature which gave light without any heat at all; such were glow-worms and fireflies. His opinion was that any substance, if there were any, which did not volatilise at all, would give a light proportionate to the temperature; that platinum, or iridium, or iron, if the iron was not burnt, would all give the same light at the same temperature, provided none of the material was wasted. Of course, if the least particle passed into the air, the flame would be coloured. In all probability the light emitted did not increase as the temperature directly, but as the square, some said as the cube, and some said as the fifteenth power of the temperature, and he was inclined to think that a slight increase in temperature increased the lighting power a great deal. In the Welsbach burner the light was not white, and that, he thought, indicated that some change was going on which made the apparent light higher than that due merely to the temperature. If carbon were heated to the same temperature, it would not give the same light.

Mr. R. S. Erskine said it would be an enormous advantage to central supply stations when these lamps came on the market. There was a great difficulty in getting satisfactory 200-volt lamps, though he did not know that they were much worse than the 100-volts. The fact was the public were now educated up to a much higher standard of light, and wanted much more than satisfied them some years ago, when they were only used to candles and ordinary gas burners. Those who were formerly well satisfied with two wax candles in their dressing-room would now put up two 32 candle-power lamps over their dressing table, and the lighting all through the house was on the same scale. They were not content with an 8 candle-power lamp that gave eight candles, but wanted it overrun so as to give ten or twelve candles, and the 200-volt lamps would not stand this; the old 100-volts stood it to a certain extent, but soon got inefficient. The great trouble with all central stations was that the lamps took more current than they used to. It looked as if these lamps would give the public what they wanted at a reasonable price.

Mr. W. M. Mordey thanked Mr. Swinburne for speaking the truth about the 200-volt lamps. The supply of lamps was a matter which really required attention, because it led to a great deal of dissatisfaction. He thought the correct plan would be for the companies to supply not electricity, but light; and, instead of persuading customers to buy lamps of any particular kind, they should make an inclusive charge, and supply them with lamps themselves. This would prevent dissatisfaction. He congratulated the Society on this paper, which he thought would mark a new epoch in electric lighting; it was the first page in a new volume, recording an invention which would rank with that of the Swan lamp, since which there had been nothing brought forward so pregnant with results. They must also congratulate Professor Nernst on his invention, and take care that he had the credit of it, and was not robbed by a number of people, who would be immediately writing to the *Times* to say that they did the same thing in their back kitchen twenty years ago. That was what always took place in the case of a new invention. Mr. Maxim had anticipated what he was about to say about the glow-worm. Professor Langley, in America, dealt with the radiation from fireflies and glow-worms in a paper a few years ago, and gave a diagram showing the total radiation, and what proportion was luminous, the result proving that the glow-worm had solved the problem which Tesla, Hertz, and many others had been working at, of making nearly the whole of the rays luminous. If they could only get a glow-worm to come and read a paper explaining how it was done, Dr. Nernst's lamp would have no future before it. One advantage these lamps possessed was that they would be able to light their cigars and pipes at them. He agreed with

Mr. Swinburne that the possibilities of the carbon filament were about exhausted; that there had been very little improvement for a long time; and it was a remarkable thing that, just when the carbon filament was failing to meet their requirements, this new invention should be made, which seemed to meet the case. It was like the discovery of gutta serena at the critical period which got electric cable-makers out of their difficulties. But, though the new lamp was evidently a very robust child, it was still a child, and it would at any rate take a little time to displace existing lamps. If lamp companies' shares went down at all on account of the Nernst lamp, he would like to buy some, as they would have time to rise again before the incandescent carbon disappeared.

Dr. Fleming asked if there was any deterioration in the quality of these lamps after a time, such as occurred with carbon filaments and Welsbach mantles; because this would be very important in considering the commercial value of the invention. If the lamp only required 1 watt or  $1\frac{1}{2}$  at starting, and, after a few hours' work, 4 or 5, it would be a serious disqualification. It was well known that most of these radiants did deteriorate after a time; with the lime light for instance, after a few minutes, the radiant quality of the lime diminished, although it was played upon by an oxyhydrogen flame at a constant temperature; and turning the lime round would markedly increase the amount of light on the screen.

Major Flood Page, having congratulated Mr. Swinburne on his paper, said he was much interested in this subject, though he was not a scientific man. When he saw Professor Nernst some months ago, in Germany, he was very much astonished to find that so young a man had been able to attain such a high scientific position. Mr. Swinburne had spoken of the carbon lamp having reached finality, but he might say those connected with carbon lamps, as he was, were as much interested as any one in this new departure. They had a higher interest than that of any particular lamp, and that was in the advance of electricity. He quite agreed that nobody but Professor Nernst could claim the credit of this invention. It was one everybody had been expecting, and it could be worked in conjunction with existing systems, so that all who were connected with electric work would find themselves indebted to Professor Nernst. In the old days they had Maxim, Edison, and Swan; and some people thought one was going to kill the other, but instead of that they all helped the general advance. This was to a certain extent going back, for Swan first worked at a red, but he believed it was an advance which might benefit all connected with electricity.

Mr. H. Colefax said several applications for patents had already been put in, which appeared to claim the benefit of this discovery, but he did not think they would prove successful. With regard to the question of deterioration, he was told by Professor Nernst, some eight months ago, that, as far as he could discover, these lamps did not deteriorate in use; of course, this could only be proved by experience; but, if it were so, it would be very remarkable, seeing that in every other form of incandescent lighting yet tried there was this deterioration. He should be glad if Mr. Swinburne could tell them what it was which limited the life of the filament, because, when he saw Professor Nernst, he did not think he had then arrived at any explanation. He was astonished at the progress which had been made in the eight months since he first saw the invention; the limit then was 200 hours, the first experiments only having attained forty hours.

Mr. Campbell Swinton said Professor Ayrton was not strictly accurate in saying that this was the first attempt to use a heated electrolyte. Some twenty years ago, Jablchhoff showed a lamp in London consisting of a strip of kaoline, along the top of which he put what he called a match, which consisted, he believed, of carbon mixed with treacle; this conducted the electricity—100 volts—until it heated the kaoline, and that then formed the conductor. He would not go into the question of how far that was an anticipation of the present invention, he only wished to correct the impression that nothing of the kind had been tried. They must all admire the great advance which had now been made, and they knew that the Jablchhoff lamp never came to anything. With regard to the lighting power of incandescent gas mantles, he had made many experiments on them with cathode rays, by which you could heat them to a very high temperature without the use of gas in the ordinary sense, and he found there was no appreciable difference in the amount of light given by a mantle of pure thorium and one with the addition of a small per-centage of ceria.

Mr. Sydney Morse said he was interested in this question on the commercial side, and especially as connected with the competition of municipal authorities, who were now commencing to manufacture and sell electric fittings, which he feared would seriously interfere with the progress of invention. They had heard that invention in conjunction with carbon filaments was exhausted, but this opened up a new industry, which he hoped would be taken up and improved by English engineers and inventors, for they could not suppose that everything had yet been done.

Mr. J. G. Lorraine asked what amount of heat was emitted by this lamp compared with an ordinary incandescent one.

Mr. A. H. Dykes asked what was the power required for these lamps. He had been working out a scheme for street-lighting, and he found the difficulty was that, while arc lamps were too large, ordinary incandescent lamps were not a great success. The lamp appeared to have many advantages for such purposes, and particularly, the volume of light-giving

material being so much larger than a carbon filament, it would have much greater penetrative power in foggy weather. With regard to lighting up, a man could go round and apply heat underneath these lamps as well as he could turn on the ordinary gas lamps.

Mr. Swinburne, in reply, said the question of the temperature of a Welsbach burner was a very large subject, with which he could not attempt to deal fully. If you examined a burner with the mantle off, there was a zone of very high temperature, which would easily fuse platinum; but most measurements made were erroneous, because they were taken with a thermopile, which never got the real temperature of the burner. The great difficulty was to get what was in the burner to the temperature of the burner. In dealing with the light given by incandescent bodies it must be remembered that the light depended on the emissivity. If the only temperature at which you got much light was very high—very close to the temperature of the gas—you must use something of very low emissivity; if it were large, the heat given by the burner was rapidly given off; and, if infinite, the temperature of the mantle would remain at the average temperature of the room, and you would not get any light. On the other hand, if the emissivity were very low, though the mantle would get to a high temperature, it would not give light for want of emissivity. A pure white body, such as pure zirconia, gave very little light, because the emissivity was too low, though the temperature was high. To get the highest efficiency, you must have emissivity enough to give plenty of light without robbing the flame of its heat too soon. From a white oxide like thorium you did not get much light, but if you added a small percentage of ceria or some other coloured oxide—it did not matter much what—you got light. A great deal of unnecessary mystery had been introduced into the subject because it was known that ceria gave some curiously characteristic spectra, but ceria was only present as an impurity. Another point was that cerium had two sets of compounds, and it was supposed that it was continually hopping backwards and forwards from one state of oxidation to another. In dealing with a subject like this, he thought the proper way was to take a simple explanation if it fitted the case, and only if it did not go to a more complicated one. He saw no reason to suppose that temperature did not account for the results if it would fuse platinum, and if it would soften the mantle, as it would. In making Welsbach mantles—though, having advised the Company, he must not say everything he knew—they were sometimes raised to such a high temperature that they softened, and then they gave more light. Professor Ayrton had quoted several anonymous authorities, but had not given the reasons for their opinions, and so it was impossible to deal with them. They involved questions of thermo-dynamics, into which there was not time to go. The case of spongy platinum was altogether different, there was a chemical combination started by the heat, which would not otherwise take place. Here there was no reason to suppose there was such a combination, spongy black would give no light, and a solution of platinum put upon a mantle would destroy its light-giving power. He believed that colour was largely a question of temperature; but you could produce different colours by using different materials. The emission was the complement of the absorption. A blue body when heated gave an orange light. With regard to a vacuum, its effect was to get rid of convection. If you tried to heat a long, thin filament of carbon, it would be inefficient on account of convection; but, with a short, thick rod, the convection was not serious. Practically, he believed these Nernst lamps would not work in a vacuum. He had not tried many experiments himself, but so he was informed. The reason generally given was that electrolysis was going on, and that oxygen was being absorbed from the air at one terminal and being given off at the other. That was Professor Nernst's explanation, but he thought there was another factor to be taken into account. It was perfectly simple on paper to electrolyse salt and get out chlorine and sodium, but when you tried it you did not get either. The reason appeared to be that the chlorine and the metal were dissolved to some extent in the fused bodies, and got across very quickly. He did not think true electrolysis took place to any extent, but there was a continual diffusion of the substances across, which was undoing the work of electrolysis all the time; but that was not sufficient to make it work properly in a vacuum. All the lamps shown were on the alternate current, but he had tested them with the direct current and found their efficiency continued right through. That was some six months ago, when they lasted 200 hours; now they had got to 500 hours, and he had no doubt they would go much higher. He did not know anything about glow-worms, and doubted whether any one else did; but he did not think such questions had much to do with the matter, it was more a question of the red-hot poker order, quite simple. With regard to the emission of light at a given temperature, it was not the least likely that there was any such simple law as Mr. Maxim had suggested. The simple law would be as to the emission of power or energy. Light was only a certain small octave of vibrations that affected the human retina, it was not distinct from heat or the radiations of still higher frequency. It was not likely there was any definite law as regarded light; probably it depended, for one thing, on the eye looking at it. With regard to deterioration and its cause, after running some time the material appeared to get crystallised; what else happened he did not know. Probably there was a gradual tendency for the rod to get uneven; then it would get more heated in one part and softer, until at last it melted.

Professor Ayrton seemed to think that the compound in the Welsbach mantle was chosen entirely for giving light, but any one who used those lights knew that the strength of the mantle was of great importance. You could get a very good light from yttria, but you could not get a strong mantle that would not warp. The manufacturer had to consider strength, portability, and durability, and one point about that was that both the Welsbach and Nernst were at a very high temperature, just short of the fusing point, at which the material very slowly evaporated. If you took a thoria mantle and put lime on it, it would give a very nice light at first, but the lime would soon volatilise, so would many other substances. Ceria went off quicker than thoria, and the result was that, after running a thoria mantle with a small amount of ceria for some time, you had a pure thoria mantle. It was not that the power of the ceria was exhausted, but that it was not there. He did not know what caused the deterioration of the lime light, probably the lime really began to sinter together, and therefore you did not get the same temperature as before. He congratulated Major Flood Page on the exceedingly broad-minded view he had taken of the subject. With regard to the early Jablockhoff lamp he had no information. His own impression was that the Jablockhoff candle was the only thing which was at all successful; that was in use in 1878. There was another lamp which depended on a hot material between the poles called the Lampe Soleil, in which an arc was struck across a surface of marble which got very hot, and finally conducted and gave an illuminant surface. The cathode-rays experiments referred to by Mr. Swinton bore out what he had said about the earths, that it was simply a question of temperature. There was another inventor, he believed, working on a lamp with cathode rays, and no doubt they could be made to give an efficiency equal to the Nernst if the earths were raised to a sufficiently high temperature. With regard to the amount of heat given off, it depended on the amount of power used. If you took 100 watts, probably nearly 100 would go off in heat, as only a small percentage of the energy was converted into light, and, until Mr. Maxim and Mr. Mordey could tame their glow-worms, he was afraid it would always be so.

#### REPORT OF THE SOCIETY OF ARTS COMMITTEE ON THE EXHIBITION OF ACETYLENE GENERATORS.

THE following is the report of the Committee on the Exhibition of Acetylene Generators at the Imperial Institute (opened June 15, 1898). It is taken from the Society's Journal.

It being common knowledge that, amongst the large number of generators constructed and sold to the public, there were some which did not conform to the ordinary conditions of safety, it was felt that, in undertaking an Exhibition of Generators for Acetylene, to be held at the Imperial Institute, a preliminary test should be made of all the generators submitted for exhibition, and that the generators which did not satisfy the necessary conditions should be rejected.

The London County Council generously placed at the disposal of the Committee premises in the Harrow-road, where the preliminary tests of all the generators submitted were carried out; and the various forms of apparatus, as they were passed, having been forwarded to the Imperial Institute, the Exhibition there was opened on June 15, 1898.

Although beyond the scope of their instructions, your Committee felt that, in the interests of the public, it was advisable to carefully test the various forms of generator working for the period of a month, as it was possible that defects which might not be apparent in the test extending over a few hours might be detected on working over a longer period.

Professor Vivian B. Lewes and Mr. Boverton Redwood were appointed as a sub-Committee to examine into the working of the acetylene generators exhibited at the Imperial Institute, and to report to the Committee as to the results obtained and as to the generators to which certificates should be granted. The method adopted for testing is shown in Appendix C.\*

As the result of these tests, the Committee advised the granting of certificates for those forms of acetylene generators, a list of which is appended, the certificate, however, merely setting forth that the generator had complied with the requirements of the various tests to which it had been submitted, and had worked safely and satisfactorily during a month's every-day use.

The Exhibition at the Imperial Institute has clearly demonstrated that many types of acetylene gas apparatus can be so constructed as, with ordinary precaution, to be absolutely safe, and that lighting by acetylene need be no more fraught with danger than are any of the other forms of artificial lighting in general use.

In granting certificates to the various makers of apparatus hereinbefore mentioned, we wish it, however, to be clearly understood that such certificate can only apply to the type of machine examined and tested by us, and must not be taken as applying to all and every class of machine which may be offered for sale by the same makers. By type of machine is meant apparatus of the designs shown in Appendix E.

We consider that the various makers of apparatus who, at so early a

\* The Appendixes are printed separately, and are not given in the Journal. See note at end of Report.

period in the development of acetylene lighting, submitted their machines to the rigid tests as to safety laid down by your Committee, and have obtained certificates, are entitled to the first consideration from the public.

There may be other forms of generators, not exhibited at the Imperial Institute, which are perfectly reliable; but we strongly recommend that no machine should be purchased from any maker or dealer unless a certificate can be shown from some competent authority to the effect that it complies in substance with the rules laid down in Appendix B, and that it has been submitted to and has satisfactorily passed the tests indicated in that Appendix. In this respect fire insurance companies could render great assistance to the public in refusing to insure without such certificate being forthcoming.

General conclusions as to the working of each generator during the testing period are given with the diagrams. All the machines to which certificates were granted worked satisfactorily, some better than the others. It is only fair to state that, in the few instances where shortcomings are indicated, the defects were in many cases remediable, and that possibly, owing to the experience gained by the exhibitors during the testing period, they may have since been remedied. Apparatus, therefore, should not be condemned because during the trials the working in any particular case was not all that could be desired.

A point of considerable interest is the volume of acetylene gas produced per lb. of carbide used in each generator. Amongst the automatic generators there were three which gave over the whole of the testing period an average of slightly more than 4.5 cubic feet per lb., the remainder varying from slightly under 4.5 to as low as 3.55. Amongst the non-automatic generators one gave an average of about 5 cubic feet, the others showing much less.

The carbide of calcium used both at the Harrow-road and at the Imperial Institute was supplied in bulk by the Acetylene Illuminating Co., Ltd., from Foyers, and was found to be throughout of excellent quality. It was weighed out and supplied to the exhibitors by Mr. Duffield, the assistant appointed by the Committee.

Although it does not follow that the generator which yields the largest amount of gas is necessarily the best, yet this factor is a most important one in the choice of any apparatus. The generators which combine the largest yield of gas with strength of material and simplicity in charging the carbide, and in emptying the residue, are those which will recommend themselves to the public.

Where the public is most likely to be misled is by the exaggerated claims made by makers as to the number of lights which a given machine will supply, and herein may possibly be an element of danger due to excessive heating caused by too rapid generation. Even if there be no danger, the overheating will considerably lessen the quantity and lower the quality of the acetylene gas evolved from the carbide, as well as tending to cause smoking of the burners, as pointed out in Appendix F.

We recommend that every apparatus sold should be accompanied by a written guarantee that it will light a specified number of burners, consuming a given quantity of gas per hour, over a consecutive number of hours without increasing the temperature in any part of the carbide receptacle, above 228° C., that is to say, the fusing point of tin.

In regard to precautions to be taken we endorse the suggestions of the Public Control Department of the London County Council and of the Corporation of the City of London.

As to licences for storing carbide of calcium, we consider that local authorities need have no hesitation in granting such licences for storage provided it be shown to their satisfaction that the material is properly packed, and that it is intended to store it in some dry and well-ventilated place.

We consider that no carbide should be purchased without a guarantee that it is free from any impurities in quantities sufficient to cause danger, and the name and address of the manufacturer should be given on each package. It should also be guaranteed to give off an average of five cubic feet per pound of carbide when used in a good generator.

As will be seen from Appendix G, the Home Office regulations allow five pounds of carbide to be kept without a licence in packages of one pound each. We recommend that, however small the quantity, it should always be kept in closed tins or bottles, under lock and key, and in a dry place. When its properties are more fully known, these precautions may not be necessary, as it is no more dangerous than many other substances in daily use.

It was not within the scope of the work of the Committee to report upon portable apparatus and lamps to be used within the house. Your Committee, however, feel it their duty to state that, safe as they consider acetylene gas to be, when generated in a properly constructed apparatus outside the building to be lighted, and in accordance with the rules and suggestions contained in this report, they are of opinion that the generation of gas within the house is not unattended with danger, except in skilled hands.

As to cycle lamps, carriage lamps, &c., though requiring only small charges of carbide, we consider that great care is required in their manipulation.

We consider that non-automatic generators, with a holder capable of taking the gas generated from the largest charge of carbide the generator will hold, are free from objections attending all automatic generator

examined by us, and we are of opinion that every generator should be fitted with an arrangement by which all air can be rinsed out of the generating chamber by acetylene or some inert gas before action is allowed to commence between the water and carbide.

We are also strongly of opinion that every generator should be fitted with a purifying chamber or chambers, in which the acetylene is purified from ammonia and sulphuretted and phosphuretted hydrogen and from other impurities.

The thanks of the Committee are due to Mr. F. G. Worth, of the Acetylene Illuminating Company, for the help he has given them throughout the investigation.

#### LIST OF FIRMS TO WHOM CERTIFICATES HAVE BEEN GRANTED.

##### *Automatic Generators.*

The Abingdon Acetylene Illuminating Co., Ltd., 97, Great Hampton-street, Birmingham.

The Acetylene Beacon Light Co., Ltd., 59-61, Colmore-row, Birmingham.

The Acetylene Gas Corporation, Ltd., 100c, Queen Victoria-street, London, E.C.

The Acetylene Syndicate, Summer Works, Summer-lane, Birmingham.

Appleby & Harris, 2, Broadway, London-fields, London, E.

Bailey & Clapham, Eagle Works, Keighley, Yorks.

British Acetylene Gas Generator Co., Ltd., Kirkcaldy, Scotland.

Ehrlich & Graetz, Lausitzer Strasse, Berlin.

Exley & Co., Byram-street, Huddersfield.

Sir Charles S. Forbes, Bart., Castle Newes, Strathdon, Aberdeenshire.

International Industrial Syndicate, Ltd., 82-84, Bishopsgate-street, London, E.C.

Liver Acetylene Gas Co., Ltd., 4, York-buildings, Dale-street, Liverpool.

Manchester Acetylene Gas and Carbide Co., Ltd., St. Simon-street, Salford, Manchester.

Midland Acetylene (Parent) Syndicate, Ltd., Cradley-heath, Staffs.

Read Holliday & Sons, Ltd., Huddersfield.

Sardi's Patent Gas Generator Syndicate, Ltd., 25, New Broad-street, E.C.

Strode & Co., 48, Osnaburgh-street, Regent's-park, London, N.W.

Thorn & Hoddle, New Tophill-street, Victoria-street, London, S.W.

Thornthorpe's Automatic Lighting Syndicate, Ltd., 37, Vittoria-street, Birmingham.

##### *Non-automatic Generators.*

The British Pure Acetylene Gas Syndicate, Ltd., 19, Castle-street, Liverpool.

Ideal Gas Co., Ltd., 8, Tacketts-street, Blackburn, Lancs.

Pintech's Patent Lighting Co., Ltd., 88, Leadenhall-street, London, E.C.

Sunlight Gas Co., Ltd. (Goodwin's System), 18 and 19, Wellington-quay, Dublin.

The Report is also issued in pamphlet form, with appendixes giving particulars of the tests, diagrams of the apparatus, &c. The price is one shilling. It can be obtained from the Secretary of the Society of Arts, John-street, Adelphi, London, W.C.

#### TREATMENT AND USE OF ACETYLENE GAS.

At a recent meeting of the Society of German Gas and Hydraulic Engineers, Fr. Liebetanz, of Düsseldorf, gave some valuable information on the treatment and use of acetylene gas.

The principal points to be kept in view in advancing the acetylene industry, he said, were the purifying of the gas, its explosive features, burners, and the production of a high-grade carbide. Impurities in the gas originate from impurities in the carbide, and consist in ammonia, hydrogen phosphide and sulphide, ammonium sulphide, and sulphurous acid. These impurities amount to 2 per cent. of the volume in some cases. As a rule, there will hardly be any help for it but to purify the gas on its way from generator to the holder, by compelling it to pass either through suitable dry and porous material, or over moist chemicals, or through metallic solutions. Ammonia has to be removed first, and this is done by washing the gas with sulphuric acid. Next comes hydrogen phosphide, which is removed by means of copper sulphate, a solution of copper chloride, nitric acid, or chloride of lime, the latter in almost dry condition. It is highly important that hydrogen phosphide be removed, for it is one of the principal causes for the sooting of the burners and the musty smell of the gas. In the case of large plants, hydrogen sulphide and sulphurous acid will also be eliminated by either bog ore, or lime, or other suitable material. After its purification, the gas should be dried by means of sawdust, carbide, or calcium chloride.

The explosiveness of acetylene has been greatly limited by comprehensive investigation, and, if accidents of that nature do occur from time to time, they are chiefly due to carelessness, or to defects in the apparatus, or to the inferior quality of the carbide. All acetylene generators constructed at present work at a pressure of either less than one-fiftieth of one atmosphere, and the temperature in the apparatus rises rarely above 100° C. Under these circumstances, an explosion without exterior cause is rendered impossible by the inherent properties of acetylene. Not until exposed to a temperature of 780°, according to others of 1000°, does acetylene decompose, and the products of this decomposition are naturally of an explosive character. If the pressure

exceeds two atmospheres, it will explode instantly if brought in contact with an incandescent body.

At a pressure of less than two atmospheres the same contact will result only in a slight puffing-off of gas in the immediate neighbourhood without further change. Neither an electric spark, an open flame, nor even fulminate of mercury is capable of exercising any action beyond the region directly exposed to heating or pressure, if the latter do not exceed two atmospheres.

A mixture of 3 per cent. acetylene and air will explode in the presence of a burning body, and the explosion results when the temperature is at least 480° C. If more than 65 per cent. of acetylene are in the air and gas mixture, the latter does not explode, this being the critical explosion point. Compressed acetylene can be exploded by neither blow nor shock, no matter what force be used. A quart bottle of steel filled with acetylene compressed to from five to ten atmospheres did not explode when dropped from any height or broken by a ram engine. The height of the fall was gradually increased to 33 feet, and the weight of the rammer to 660 lbs., without having the least effect. It is evident that the danger from explosion of acetylene has been much exaggerated.

The burner question is the one least solved in acetylene practice. None of the present constructions fills the bill to entire satisfaction, as most of them make too much soot. In devising a burner three important points should be considered: first, to avoid heating as far as possible; second, to regulate the air supply most carefully; third, to see that the flame is in contact with the larger possible air surface. This is to promote the combustion of the carbon contents in the gas from which the bothersome soot in present burners chiefly originates.

As carburettor, acetylene has not been a success. It improves retort gas but little, and is too expensive, if compared with carburettors in common use. Attempts to enrich water gas by means of acetylene proved almost entire failures. Of most practical value is a mixture of acetylene and fat gas, as used for car-lighting on the Prussian State Railways, and about to be introduced on the other German railways. The proportion of the mixture is 72 per cent. of fat gas and 28 per cent. of acetylene. There are at present twelve large carbide factories on the European Continent.

WHILE the late Sir George Baden-Powell was not an astronomer, it will be remembered that he conveyed, on his yacht *Otaria*, the expedition to Nova Zembla to observe the total eclipse of the sun, August 9, 1896, when Mr. Shackleton secured his memorable photograph of the "flash" spectrum at the end of totality. The spirited and determined way in which he undertook to put the party in the path of totality at that remote station may be appreciated from some remarks in his description of the expedition before the Royal Astronomical Society, December 11, 1896 (*Observatory*, 20: 44): "In the first place, it was necessary, in my opinion, to get some qualified astronomers with their instruments to Novaya Zemlya. I happened to wish to go there for other purposes connected with meeting my old friend Dr. Nansen. Hearing that I could be of some service to science, I was glad to devote all the energies I possessed, and my ship, to taking these astronomers there. We had some difficulty in getting there in time, but, as has happened before in certain things we have undertaken in that good ship, we got there well in time." And, once arrived at this trying Arctic observing station, the heartiness with which he entered into the observations may be judged from some later sentences on the same occasion: "They entrusted to my charge the coronagraph, and all the members of my crew not only took their part with extraordinary willingness, but also showed great delight in what they considered an interesting observation, considering that they had their reward in being allotted positions around the instruments under the command of these distinguished astronomers. Right at the last moment, however, the siderostat would not work. It had been set up and thoroughly adjusted, but at the last moment, when the moon had got a long way over the sun, it would not work; and, looking through the coronagraph telescope, I saw the image pass steadily but surely across that bit of ground glass which we all watched so anxiously, and nothing that the devoted energy of Mr. Shackleton could do would make it work properly. This happened almost up to the point of totality, but, with the dash of genius, Mr. Shackleton certainly went for that siderostat with what we uninstructed persons would call rashness, and dashed back into the hut saying, 'That will do;' and it did do. I saw the image in the centre of my ground glass, which I had then to take out and begin the series of photographs I had been instructed to take at various intervals during totality; and I think one of the happiest moments of my life was when, somewhat dazed, because immediately after totality the burst of sunlight was so great, I had sufficient senses left to slip in the ground glass to see where the sun had got to, and saw our old friend right in the centre of the field." Commenting on the inadequacy of the appropriations of public money for eclipse expeditions, he added: "But I do say for myself—and I have a special command to do so for my wife—that if ever a yacht is wanted to take willing people to see another eclipse, they will know where to find it, if we are free then." Surely this was an expedition that deserved to succeed so brilliantly in the midst of general failure due to bad weather.

## LANTERN MEMS.

"It is fourteen years since I showed the members of this Society the improved projection microscope I designed with the view of getting better results than could be obtained by the patterns then existing." Such in substance was what Mr. Lewis Wright said to the audience at the Quakett Club a week or so ago, prior to a demonstration he gave. He then proceeded to explain the development of the instrument since that time. Generally speaking, the improvements consist in making the apparatus stiffer, so as to secure steadiness, an increase in the aperture of condensers and objectives, and the use of improved eyepieces.

MICROSCOPISTS, and those who contemplate using projecting microscopes, will do well to remember that all the best work is now done with eyepieces, whereas in the earlier models the projection was made direct from the object-glass, and sometimes with the addition of amplifying lenses. It is a coincidence that at the time when negative eyepieces in field and marine glasses are giving place to telescope eyepieces, in connexion with the Porro lenses employed for shortening the length of the instrument and reversing the image, the concave amplifier of the projection microscope is put on one side for the compound eyepiece.

THOSE who witnessed the demonstration at the Royal Institution by Sir David Salomons, some three years or so ago, will remember how fine the definition of the enlarged image was, by eyepiece projection, in comparison to that by amplifier, and now Mr. Lewis Wright obtains an increased field of view by modifying the projection eyepiece. Instead of the small field lens, generally fitted to this form of eyepiece, a meniscus lens of the full aperture for the tube employed is used, and in consequence a much larger field obtained, with very little loss of flatness of field.

To be able to project an object so that it is magnified when on the screen to 2500 diameters with the limelight is an achievement, and, if the electric arc light is employed, and an objective of half an inch equivalent focus, a magnifying power of 5000 diameters can be obtained. It was shown that many objects appear much more distinct when on the screen if projected with a low-power objective

and a high-power eyepiece, while others are better with a moderate or low-power eyepiece. It will thus be understood that a selection of eyepieces is necessary if the particular object being shown is to be projected at its best.

In order to obtain the widest angle of light possible, four lenses are employed for the lantern condenser, and a modification made in the lens for parallelising the light, while the optical system generally is rearranged so as to secure the greatest freedom from spherical aberration. Altogether, the demonstration by Mr. Lewis Wright left little to be desired. In large rooms it is almost impossible for those of the audience some distance from the screen to see the detail of the microscopic objects, hence the great value of an opera-glass being employed in order to appreciate the projections. This remark also applies to many demonstrations of a scientific character, especially those given at the Royal Institution, and with members of the latter it is very usual for them to use a binocular glass.

THIS was forcibly brought to mind at the last Friday-evening meeting before the Easter vacation, when Lord Rayleigh lectured on "Transparency and Opacity," and in the course of same produced a spectrum by means of a new spectroscope, showing the double-sodium lines. This was possible by using ten prisms arranged in a length of twenty inches, giving great dispersion. It was explained that a variation of temperature quite upset the results obtained by the bisulphide prisms, owing to the hotter air refracting the rays less, whereas with the new prism the error was corrected by change of focus, a small variation of 5° F. or 2° C. being quite sufficient to spoil the projection in these delicate demonstrations. By placing the prisms so that the apex is downwards or vertical, instead of horizontal, as in the bottle form, the difficulty is surmounted.

As an illustration of opacity, snow flakes were mentioned as particles through which light was not transmitted or only refracted to such a small extent that they look as objects seen by reflected light only. When, however, they began to melt or are of a rainy order, then light passes freely, for the interstices are filled with a fluid more nearly approximating to the density of air; and then, as an experiment, he showed that particles of broken glass in bulk would not allow light rays to pass, but, when the vessel containing them was filled with a fluid, such as cedar oil and bisulphide of carbon, then the light passed freely.

THIS has an important bearing on achromatism, for it was shown to be possible to so use glasses of different densities and fluid combined that made the refractive index of the whole very uniform. Bisulphide of carbon and benzole gave practically equal indices of refraction. A simple experiment, to show achromatism, was made with two prisms, one of crown glass that refracted the white light

as a spectrum to the right, and another prism of flint glass that refracted to the left. These were so proportioned for density that, when placed together, an achromatic prism was produced, and the beam, although deviated to the right, was white light.

A CORRESPONDENT recently, in THE BRITISH JOURNAL OF PHOTOGRAPHY, questioned the colour of calcium carbide residue as indicating the heat to which it had been subjected during the process of decomposition while liberating acetylene gas. As my remarks were based on the statement of Professor Vivian Lewes in his lecture at the Society of Arts, I now quote from notes made at the time, viz.: "Lime tells the tale of the temperature: white lime deposit, 400° C.; if yellow, 600° to 770° C.; black, over 780° C."

A POSSIBLE explanation of some black residue not yielding any more acetylene after further immersion in water is that it becomes coated with a tarry or protective coating. As Professor Lewes says, "the acetylene generated has to pass through the external layers, which, as shown, may be at a temperature above the point of its decomposition, and it is under these conditions that a considerable volume of gas is lost, and the tar, often found in the residue, or distilled out in the generator and tubes, is formed." The italics are mine.

G. R. BAKER.

#### STEREOSCOPIC PROJECTIONS.

For the benefit of those among your readers who take an interest in projections I am going to explain a very easy way of causing them to appear "solid"—that is in relief—which greatly adds to the attraction of the now familiar entertainment.

Two lanterns—yours and one borrowed from a friend, for instance—two

Place the two screens, S and S', at right angles to each other, and some distance apart (fig. 1), situating the lanterns, R and L, so that the images they project may fall one on the back of each screen (as they are to be viewed by transparency), and, in order that the said images be of exactly the same size and also in such a way that the optical axes of the lanterns cross each other in a point X, which must lie on the vertical plane which bisects the right angle formed by the two screens. The spectator must place his nose (this sounds comic, but it is the simplest way of putting it) at X; and the mirror, starting from X towards D, is to coincide with the bisecting plane just named, and must have its reflecting surface facing S'.

Now let us suppose the spectator in the said position, in which he will have the left eye seeing outside the mirror, and the right eye looking into it; insert the left slide in lantern L in the usual way (*film facing screen*) and put in lantern R the "right slide," with the film towards the condenser; the view (from the left slide) will be seen in the ordinary position on screen S, and the same view (from the right side) will appear reversed on screen S', that is with right changed into left, and *vice versa*. If he now looks straight before him, his left eye will see the view on S by direct vision, and, as the mirror X M forms an angle of 45° with either screen, the right eye looking into it will see the view on S' in its normal position, which will cause it to immediately coincide stereoscopically with that on S, thus forming a wonderful, solid, lifelike rendering of the whole, the right-side image virtually appearing at A B, but without being visible to the left eye or in any way interfering with its vision, as the mirror X M completely prevents either eye from seeing anything but what it is particularly intended to see. A small opera glass may be used where sight is defective.

The mirror can be made to pivot on a vertical axis at X to allow for differences of separation between the eyes of the various spectators.

It is not necessary that the lanterns should be identical, no more than their lenses; but it is necessary that the projected images should be of exactly the same size, otherwise the stereoscopic superposal would be impossible.

Although I have practically seen that any lanterns, lenses, slides, and

screens, a small hand mirror, and of course the positive transparent stereoscopic slide, cut in two (so as to have a "right slide" for the right eye, and a "left slide" for the left), are the only items necessary for the performance.

mirror will "do," it may be interesting to mention that I usually take the views with Anschütz's stereoscopic camera, fitted with Goerz lenses (f-7, 7), and employ for the projections a couple of Ross's new universal combination lanterns, quarter-plate size, lighted by Ross-Hepworth electric arc

lamps, and to which I apply either a pair of Ross's extra-rapid symmetric anastigmats ( $f=5, 6$ ), or else the same Goerz lenses used in taking the views. My mirror is an optically plane one, also by Ross.

It will be objected that little or no superiority can be gained by this method over the stereoscopic effect produced by the ordinary stereoscope, since, owing to the magnifying power of the latter's lenses, the images are seen in what appears to be "life size," because the viewed image can be made to coincide with the real object by looking with one eye at each. To this I reply that my system will always have one advantage over the other, viz., that the objects on the first plane can *very often* be projected to real "life size," which in many instances—for example, in the case of a portrait—produces quite a startling effect.

A similar contrivance, founded on the same principle, can be used to view stereoscopic transparencies of large size—whole-plate for instance. In this case the plates are placed vertically, as shown in fig. 2, in which A B is the left picture and B' A' the right one, which should be reversed. The distance between plates and mirror is of no consequence whatever, provided the four points X O D C' form a square (C and C' being the approximate centres of A B and B' A'). A light behind each plate will, of course, be necessary, as well as a ground glass to soften its brilliancy.

These transparencies may be either enlargements to any size, from ordinary stereoscopic slides, or they may be made with two cameras placed together, or else with one camera properly shifted when taking the second of each pair of photographs. I have taken a great many very successful ones with two whole-plate cameras fitted with splendid Zeiss's convertible single anastigmatic lenses of  $16\frac{1}{2}$  inches focus, and with Thornton-Pickard time and instantaneous shutters set at the same speed and worked by a single pneumatic ball.

The results thus obtained are generally far superior to those given by the ordinary stereoscopes, since the grain of the emulsion is quite done away with, which gives a fineness of detail impossible to obtain otherwise. In the case of objects taken full size, as flowers, insects, small animals, jewellery, and many objects of art, the effect cannot, to my knowledge at least, be superseded by any other method in existence. Landscapes and seascapes likewise appear vastly improved.

A pair of magnifying spectacles can, of course, be used when necessary or convenient.

To conclude, I scarcely need add, it being obvious, that the mirror can be used by either eye in all cases, provided its reflecting surface be placed towards the reversed picture, which must evidently always correspond to the eye in question.

M. DE RISCAL.

### STEREOSCOPY ON THE SCREEN.

MANY have been the attempts, in recent years, to revive an interest in that once most popular instrument, the stereoscope. At one time no drawing-room was considered complete unless one of these contrivances was provided, and it was looked upon quite as much as a necessary as the inevitable piano. Attempts also have not been wanting to project stereoscopic images upon the lantern screen, and some important experiments in this direction are too recent to need much remark. Such attempts have generally necessitated the employment of two lanterns, so that two images may be superposed, and means provided that one eye only can see each image, as in the ordinary table stereoscope. This has been achieved in various ways. For example, the left and right-eye images may be flashed alternately upon the screen by means of a revolving sector in front of the lantern lenses; or the two lanterns may throw images of different colours on the screen, to be viewed by the spectators by means of coloured spectacles. Lastly, we have the method of using polarised light for the projection of the images, and viewing them by means of suitable spectacles.

Mr. John Henry Knight, of Barfield, Farnham, has accomplished the projection of stereoscopic images in a far more simple and inexpensive manner, and employs one lantern only. His method formed the subject of a paper read before the Camera Club on Monday, the 27th ult., and the successful demonstration which accompanied the reading of the paper was highly praised by an appreciative audience.

Mr. Knight throws the two stereoscopic images side by side on the lantern screen, so that together they cover the space occupied by an ordinary lantern slide, and they are then viewed by a special form of "scope," which each of the spectators holds in his hand and applies to his eyes. The construction of this appliance, which is of an extremely simple character, and does not employ lenses or other expensive fittings, will be readily understood on reference to fig. 1, which is a plan of the apparatus. D is a flat board, measuring about four inches by two and a half inches, and against it is a vertical face plate, x, which is pierced with two eyeholes, a, a. On D are two mirrors, B and B', the latter being fixed on a central pivot, so that it can be adjusted to suit different sights. C is a diaphragm, or screen, of blackened cardboard,

which has a length of about one foot and a depth of three inches, and it has at its further end an adjustable piece of the same material, c'.

A "scope" of the above construction having been handed to each person present, a double disc diagram, as shown in fig. 2, was projected upon the screen, and the spectators were instructed to adjust their mirrors until the two images coalesced and the vertical and horizontal bars upon them formed a cross. This having been done, various examples of stereoscopic photography were thrown upon the screen, and stood out with marvellous solidity.

As Mr. Knight was careful to explain, the centres of the two pictures on the screen were about four and a half feet apart, and therefore special means were required, not only to throw the images stereoscopically, but to adjust those images for every one present, whether near or far from the screen. This is secured by the adjustable mirror, B', and the diaphragm or screen of cardboard, c. The end piece, c', is not required at all if the spectator be near the projection sheet; but, if he be at a distance of, say, more than twenty feet, then the extra piece, c', becomes necessary to screen off other visual images which may become intrusive.

There is naturally a certain loss of light entailed by the use of this scope, but at the Camera Club, where the lantern is an electric one, there is plenty to spare, and the loss did not become apparent. A greater objection was found in the dwarfing of the image, which Mr. Knight attributes to an optical illusion. As he puts it, "There appears to be a dwarfing of the image altogether by viewing it through a mirror or even a tube; the same is noticed when one first looks through an astronomical telescope, say, at the moon. Although the telescope may magnify linearly fifty or eighty times, the moon appears to be only fifteen or twenty times larger than one is accustomed to see it with the naked eye. Again, to expect to see the stereoscopic views on that screen as bright and as large as an ordinary lantern slide would be something like expecting to see all the detail in an ordinary stereoscopic view, two and three quarter inches square, that one would get in a  $12 \times 10$  photograph." Mr. Knight concluded his remarks by expressing the hope that we should one day be able to see animated pictures on the screen, not only stereoscopically, but also clothed in their natural tints.

Mr. Knight's apparatus may be regarded as a most useful contribution to the solving of a problem that has engaged the attention of many thinkers. It gives as good, if not better, results than any contrivance previously devised; and it may be mentioned that the pictures which he showed were by no means of the best, many of them having been copied from paper prints. Indeed Mr. Knight apologised for having been unduly hurried in his preparations for the demonstration, an apology which was readily accepted when he added that his principal object was that the Camera Club should have first view of the results which he had obtained.

### COLOURING LANTERN SLIDES.

#### III.

HAVING accomplished the tinting of a slide in the manner described in a previous article, it is then subjected to a drying operation, or what is perhaps more properly termed a hardening of the colours that have been laid on. At this stage the greatest possible precaution must be taken to avoid dust, in fact all through the work dust is very liable to give a considerable amount of annoyance. During the operation of colouring, a speck of dust or a small hair is easily got rid of by means of the point of a dry brush, but this, occurring when the slide is only partially completed, seldom gives as much trouble as is the case when the slide is quite completed and all the blending has been nicely accomplished.

As a rule, even any one moving about a room where colouring is being conducted is quite sufficient to raise a plentiful crop of those annoying little hairs or specks of dust which seem to take an especial delight in settling down just on the most vital parts of the slide. A worker should therefore take such precautions as will avoid any of these annoying visitors.

For drying a slide, perhaps there is no more convenient method for an amateur worker, or one who merely does a few slides now and again, to adopt than that of placing the same under a glass shade, such as are in use as bell glasses in a garden. The application of more or less heat

is sometimes recommended to accomplish this drying operation more rapidly, but my experience has taught me that this is a mistake, for it generally does more harm than good by introducing dirt. The best method, in the writer's opinion, is to select a warm room and to cover the slides with the bell glasses, leaving them undisturbed until the colours have got somewhat hardened. This operation of drying will, of course, vary according to the nature of the pigment used in colouring, for some colours are much better driers than others, and some workers can colour a slide by means of dabbing, using the necessary pigments in a much drier or harder condition than others. The introduction of a little mastic varnish with the pigments used will generally help to dry a slide within a reasonable time. On the other hand, although megilp is an invaluable vehicle in many ways, it does not dry nearly so rapidly as mastic varnish.

Some workers prefer to treat their coloured slides to a binding operation by employing a cut-out mask slightly larger than the one it is eventually intended to employ. This mask is laid over the wet painted surface, when a cover glass is bound on in the usual manner and set aside to harden, but this method does not permit of as much air reaching the surface of the slide as the bell-glass method, and there is a strong liability of dust settling down on the slide during the time it is being handled for binding on the cover glass. It has, however, many advocates and is largely practised.

After a slide has become nicely hardened, it has then to receive what may be termed "the finishing touch," for up to this stage it will present a somewhat oily or grainy appearance, lacking in the brilliancy and sparkle which is so apparent in all high-class coloured slides.

To obtain this desirable result the hardened slide has now to be varnished, and it is just here that a little knowledge is so necessary to successful results. For a long time I got along all right in this work up to this finishing stage, where, as a rule, books of instruction fail to guide a beginner in the work, and so I set myself to reason the business out, and, as the result of many trials with varnishes of all descriptions, I finally hit upon the following, which yields a magnificently clear appearance to a slide that has been coloured by means of oil pigments.

To prepare this varnish two ingredients are necessary; first, a quantity of Canada balsam, in the condition used for mounting microscopic objects. Any optician will supply this in small bottles, and a little of such will make quite a large quantity of the mixture we are requiring. The other ingredient is our good old friend, turpentine. This must be of the purest possible quality, into any quantity of which sufficient of the Canada balsam is added to provide a thinnish varnish. It will take a little practice for any one to mix this just to the proper consistency, but after once hitting the proper quantities, which is best judged by the manner in which it flows over the surface of the slide, such is known for all future time. After mixing, the varnish should be allowed to settle for several days, so that any impurities may go to the bottom. The upper portion is then decanted off into an absolutely clean bottle free from all dust, and, whenever this operation of varnishing is being performed, this arch enemy, dust, must be guarded against at all costs. If properly made, this varnish will preserve a beautiful water white appearance and flow on the slide with a delightfully even wave. In applying it, however, to the surface of a coloured slide, a few words of caution are necessary, for it must be borne in mind that, seeing an oil pigment has been used, and that turpentine is a strong thinner or solvent of such pigments, the application must be effected so as to avoid any deterioration of the coloured image, and, strange as it may appear to some minds, this thinning property of turpentine is invaluable in the operation we are considering, for it not only tends to further blend all the colours nicely together, but, in conjunction with the Canada balsam, it imparts a beautiful sparkle to what previously was a misty oily appearance.

When applying the varnish, it must be poured on in one corner, and the varnish caused to make a rapid flow without stopping over the entire surface, pouring off the surplus varnish into another bottle.

At all costs this operation must be performed cleanly, and any of this surplus varnish should not be employed until it has again settled and been decanted.

In about five to ten minutes' time, after the slide has been varnished, it will, if held a slight distance from a clear, bright fire, have become sufficiently hardened to bind up and finish under a cover glass.

No sooner has any one for the first time conducted this operation of varnishing than he will have observed that, after the varnish has been applied, the previous depth or density of the pigments will have become considerably lowered, so that an experienced worker will readily know how to allow for this reduction when laying on the tints in the first instance.

To attempt to enumerate a tithe of the various kinds of subjects that fall to a colourist to deal with would be impossible, therefore only a few of the leading subjects can be dealt with in articles of this description. As a rule, landscapes must be dealt with according to their seasons, and not too much labour expended upon the introduction of cloud effects, for these may be obtained in a marked degree by introducing or blending such effects as sunrise or sunset with the three colours named and used in conjunction, viz., Prussian blue, crimson lake, and gamboge, and, when they are introduced to provide any special effect, their use alone will impart quite a sufficiency of atmosphere without introducing any clouds into the picture.

Among other subjects which are specially amenable for colouring in lantern-slide work may be mentioned such pictures as mottoes and introductory slides, examples of which we see in "A Merry Christmas" slide. In pictures of this description there is an illimitable scope for the exercise of taste, not only in designing the original black-and-white sketch or block picture, but likewise a very wide range of effects to be produced at the hand of a colourist. A common form of such a slide may be described as follows: a well-chosen floral design, such as a wreath of flowers composed of Christmas roses (the *Helibore Niger* of our gardens), is made to form the main feature of the picture, into which is introduced the customary Christmas greeting, and over all is shown the figure of a robin, with his little bill partially open, warbling his Christmas welcome. A slide of this description is by no means difficult of production. The floral design is first tastefully drawn in line on a pure white card, care being observed not to fill in the parts as are eventually to appear in a brightly coloured form, such as the pinks and reds and greens of the coloured slide. By this means the negative will print the glass positive in such a manner that these parts are represented by bare glass in the slide, and, of course, any transparent or semi-transparent pigments will work over the parts much better and yield greater brilliancy than were those in the positive showing any reduction of silver.

A design of this description can be nicely executed by first introducing a round centre or patch of crimson lake, meeting which and running out to the edges of the slide is a nicely graduated edging of Prussian blue. The latter colour is first laid on and dabbed similar to the working of a sky, so as to appear darker at the edges, and blending or shading gradually away until the point where it meets the crimson lake.

The floral design represented by the Christmas roses is nicely tinted by using a mixture of gamboge and Prussian blue, for the leaves in a picture of this description are generally represented as of holly, with a charming bunch or two of red berries. The roses are easily tinted a very pale pink. The robin, together with the lettering, is attached on the original sketch for the purpose of yielding the negative. The breast of the robin, of course, is easily matched with a mixture of gamboge and crimson lake, with just a *souppçon* of burnt sienna.

Such a subject as the above is perhaps one of the very best any beginner could select as his first trial subject in lantern-slide colouring, for it embodies three primary features, viz., dabbing, brush colouring, and blending, and when these are completely mastered a worker may be said to be proficient.

T. N. ARMSTRONG.

#### A VISIT TO THE SCOTCH AND IRISH OXYGEN COMPANY'S WORKS AT POLMADIE.

It is extremely gratifying to be able to place on record the fact that another lantern season has passed without the slightest form of accident having to be noted in connexion with the employment of compressed gases in cylinders, and this in the face of a largely increased use of them, both in connexion with cinematographic and lantern projection. This fact strongly confirms the wisdom displayed in framing such a stringent set of conditions which governs the conduct of the various oxygen companies that now cater so successfully for the public requirements in limelight projection, but probably very few even of those of whom it may be said that they take an active interest in limelight work really know the extent of the precautions taken by those in charge of our oxygen-manufacturing companies, for at every turn safeguards against an accident of any description are imposed, until it may be truthfully said that, so far as human foresight is concerned, there is no possibility of an accident occurring from the employment of compressed gases in cylinders, and without the intervention of some criminal or wilful intent an accident is an impossibility.

A visit to any of our gas-compressing companies' works must at all times prove a matter of considerable moment to those taking an interest in limelight work, and it was with no little amount of curiosity and pleasure that the writer, on the invitation of Mr. Carty, the courteous manager of the Scotch and Irish Oxygen Company at Polmadie, near Glasgow, recently visited these extensive works, where everything in connexion, not only with the manufacture of the various gases is being daily carried out on a very extensive scale, but likewise the testing of new and old cylinders is most scrupulously attended to. The Company employ a very large staff of skilled mechanics, who are regularly engaged in making the various cylinder valves, fittings, &c., as well as turning out a large supply of automatic regulators and fine adjustment valves for the regulation of gases, all of which are of the most recent pattern.

To attempt to describe the entire precautions which are taken at every turn for the public safety in connexion with the charging of cylinders would be a difficult task. It may, however, be briefly stated that no cylinder is permitted, under any pretext whatever, to reach the pumping room without first going through the inspection or test room, and every cylinder on arriving at the works is first carefully inspected by a skilled workman, who, by means of private marks upon the cylinder, is enabled to say definitely the period that has elapsed since such a cylinder was not only tested, but reannealed, and any cylinder coming under his

observation that does not bear upon its shoulder the required proof of this important safeguard is at once set aside as being ineligible for charging with gas until it has not only been reannealed, but at the same time has been subjected to the required pressure, viz., 3360 pounds per square inch.

This testing is a very important part of the routine at the Scotch and Irish Oxygen Company's work, and a description of how an uncertified cylinder is tested will, no doubt, prove of interest to the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY.

All cylinders which do not bear the required test mark are placed, one at a time, in a water jacket. This may be described as a deep, narrow well sunk in the earth below the level of the ground, the cylinder standing on end, nozzle upwards, just above the surface of the water. When the cylinder is inserted in the water jacket, a very strongly made collar is caused to surround the shoulder of the cylinder and at the same time also enclose all parts of the jacket. This collar is held so firmly down by means of an hydraulic pump as to prevent any escape of the water upwards from the jacket. When the cylinder is firmly gripped by the hydraulic collar and pump, pressure is applied to the cylinder, and as the pressure increases, which is easily seen by referring to the gauge attached to the pressure tube, the cylinder, if in good condition, expands, and, in consequence of this expansion, the water in the jacket is forced up in a glass gauge, which at once shows the amount of stretch the cylinder has yielded, and, when the gauge indicating the pressure has reached 3360 pounds per square inch, the pumping is stopped and the stretch of the cylinder noted.

On the release of the pressure on the cylinder, the stretch is again carefully noted, and any cylinder that does not return in elasticity to its original dimensions, as previously indicated on the low-pressure gauge, is at once rejected as unsafe and probably requiring reannealing.

The time taken in testing, say, a forty-foot cylinder in the manner described is about ten or fifteen minutes, and all the various gauge tests are carefully noted in the record book, where the performance, and date, and history of every cylinder in circulation is carefully recorded. It is quite surprising how the officials of the Company can give the history of almost every cylinder that leaves their works. They can even form a very good guess as to the particular kind of use, such as theatrical, or optical, or medical employment any cylinder has undergone, even to the names of those who may have used and had charge of the cylinders for years back, and the genial Manager (Mr. Carty) facetiously remarked, on the occasion of our visit, that, as a rule, showmen took better care of their cylinders than any one else.

After being tested and marked, the cylinders are passed on into the charging room. Here similar precautions are taken to prevent even the slightest possibility of any errors, and it is abundantly evident that the precautions imposed some years ago, on the occasion of the bursting of a cylinder from the effects of the mixed gas it contained, have, for once and all, placed a repetition of such a calamity beyond the pale of possibility; for, with the means now employed, it is quite impossible for even a careless workman to pump hydrogen into an oxygen cylinder or *vice versa*. Within recent years fresh and improved pumping machinery has been laid down, and by this means all pumping connexions are fitted with blow-off or safety valves, the effect of which, even supposing a workman from neglect, failed to release a cylinder until it was overcharged, is that the safety valves being self-acting, blow off when a pressure of 1800 lbs. per square inch has been reached, and as many as six or eight cylinders can be charged from the one pump simultaneously, so that the time taken to charge a cylinder does not occupy many minutes.

In striking contrast to the present method of charging cylinders it is interesting to recall the practice that prevailed in the United States, where cylinders were first introduced. In the early days of iron bottles used for storage of compressed gas, resort was had to hand pumping, and it took some labour and time to get a twenty-foot supply at a pressure of even 25 lbs. per square inch, a period of over half an hour being required to pump such a quantity by means of the hand.

In America, however, the cylinders were never charged to anything like the same extent that has been in practice in this country; but, with the excellent quality of soft steel used in the manufacture of the cylinders, the pressure in this country can certainly not be deemed excessive. The lower pressures originally adopted in America were based upon quite a different class of cylinders to those employed in this country; but the fact remains that, with the great precautions which are now observed, not only in regard to every new cylinder, but likewise as bearing upon those of older construction, 120 atmospheres is quite within the lines of safety, and this has been abundantly proved by experience.

It is not only, however, in connexion with what may be termed the cylinder shell that the utmost precautions are taken. The same applies, under Mr. Carty's supervision, to every detail in connexion with the valves and cylinder fittings, each and all of which are made and fitted on the Company's premises, under his special observation.

When cylinders were first introduced, there were not wanting those who predicted utter failure of the system by reason of the difficulty of delivering the gas from the cylinder to the jets at anything like a regular pressure, and some of the best and most experienced lanternists in the kingdom gave it as their opinion that it could never be accom-

plished satisfactorily in cases where cylinders were charged to a pressure of 120 atmospheres.

This desirability was soon appreciated, and as early as 1884 a form of regulator was patented; this was followed by several other forms of governors, notably those of Beard's and Clarkson's, both of which, it may be said, at once removed the only real objection that could be urged against the use of gas direct from the cylinders.

The early forms of these governors, although in reality quite effectual in working, were liable to injury by reason of rubber being employed in their construction; these in turn have been followed by the more modern form of regulators, of which one of the best is that of Briers' metallic, in which rubber is entirely discarded; and this is the form of regulator that the Scotch and Irish Oxygen Company have specially adopted and which they manufacture on a very extensive scale. All regulators, from the very first, by reason of the fineness of fittings required, have naturally been more or less expensive; but the Scotch and Irish Oxygen Company have made a fresh departure by arranging for a system of hiring out, at a merely nominal charge of sixpence for each regulator per night, instruments of guaranteed perfection, and no regulator is permitted to leave the works without first being carefully tested for efficiency.

In addition to the manufacturing of these regulators on a very large scale, the same Company has placed upon the market a very efficient fine adjustment valve that has become very popular in the hands of expert lanternists.

To any one taking a keen interest in lantern projection a visit to the Scotch and Irish Oxygen Company's works at Polmadie must prove not only interesting but highly instructive. Certainly a visit to such places would do more than anything else to dispel any latent fear or idea of danger in connexion with compressed gas in cylinders than anything else we know.

#### IMPROVEMENTS IN LIGHT-HOUSE APPARATUS.

At a recent meeting of the Institution of Civil Engineers, a paper on "Improvements in Dioptric Apparatus for Lighthouse" was read by Mr. W. T. Douglass, M.Inst.C.E., and Mr. J. A. Purves, B.Sc. The paper was devoted to a description of the advantages secured in practice by the *feux-éclairs*, or "lightning lights," introduced by Mr. Bourdelles in 1890, and to an investigation of the financial aspect of improvements effected, from which it appears that a more efficient and characteristic light is obtained at a greatly reduced cost.

It is universally admitted that, sufficient power being granted, the fixed light is, from the point of view of visibility, the light *par excellence*. It is kept constantly in view, and a bearing can be taken from it, and a course steered to it, with absolute certainty when it is once picked up. The same statement could not be made with reference to a slow revolving light; there is so long a period of time between light and darkness that the sailor is apt to lose patience; and, if he happens to miss one or more flashes from any cause, as, for example, from the vessel falling into the trough of the sea, or from the obscuration of the light by masses of spray, or even possibly by a passing vessel, his nerve may become unstrung and a disaster result. This danger and difficulty the *feu-éclair* readily surmounts, as its lightning flash or flashes, occurring every five seconds with persistency, render it for all practical purposes a fixed light, while it confers the further advantage of a positive characteristic.

There was a waste of light when it was allowed to rest on the eye longer than the time necessary for complete perception, which period was one-tenth of a second. Light might be economised so that greater intensity should be given to the beam emanating from the apparatus. This is the underlying principle which governs the system of illumination by *feux-éclairs*. Elaborate experimental investigation has been made, notably by Charpentier, to determine the exact time which an intense ray of light falling on the retina requires for full perception. This time is between 0.08 second and 0.125 second. A mean between these periods was accepted for working purposes, and the French light-house service accordingly fixed the standard duration of a flash at one-tenth of a second. In future, therefore, this law determines the maximum effect of an optical apparatus, and any "wire drawing" of the flash beyond these limits means want of economy and a diminution of the efficiency of the light. In both systems it is equally easy to produce group-flashing lights by the simple expedient of breaking up the faces of the panels.

The commercial aspects of these new lights, dealt with in three tables, are calculated from Mr. Allard's formula. As is well known, the actual candle power of a light as arrived at by photometric experiments is much less than that given by this formula. The object of the authors in giving these tables was, however, to institute a comparison between new and old forms, and for this purpose Mr. Allard's formula was available. The undesirability, from an economic point of view, of using the old form of apparatus is made obvious. Compared with hyper-radiant apparatus with six sides, *feux-éclairs* of the first order, with corresponding two panels of 155°, showed a saving of no less than 1784; while, compared with a hyper-radiant with three sides, each side giving a group of two flashes, *feux-éclairs*, with a group of two flashes, two panels of 135° each showed a saving of 3000.

The new system of *feux-éclairs*, instead of the hyper-radiant, could thus be employed with a great saving of cost. Thus, in place of the gigantic and expensive hyper-radiant, such an apparatus as that installed during last year at Armen, on the west coast of France, could be set up. This apparatus is of the second order, and the luminary is an incandescent gas light. The gas is formed from mineral oil and is under pressure. The light of this apparatus is equal to no less than 300,000 candle power, while its cost, including rotary mechanism, mercury bath, lamps, &c., amounted to 1920*l.*; while the cost of a hyper-radiant of equal candle power would be 5695*l.* Should a greater candle power be desired, all that is necessary is to adopt the double apparatus system now used in France, a sample of which is that of L'Ailly, now being installed at Dieppe, the candle-power of which will be 600,000.

This novel system has many advantages from an economic point of view. It permits of small apparatus being used with small lanterns and accessories. It renders the use of smaller burners possible, and consequently reduces the consumption of oil. One standard form of apparatus serves every purpose. New designs need not be prepared for every new light, and therefore new and expensive dioptric elements have not to be calculated, moulded, and ground. Any desired alteration in characteristic can readily be made by altering the cam attached to the eclipser. It may further be remarked that, by using such a standard light as, say, a third order for first, second, and third-class lights, sailors would not be perplexed by the endless and uncertain variations of the power of lights as given in the Admiralty List. All lights would have the same intensity of beam, whatever the number of flashes. All would have an equal luminous range in clear weather, and penetrating power in fog, and all an equal geographical range so far as power of light is concerned.

The advantages to be derived from this system can be summed up in a few words: (1) Greater characteristic distinctiveness; (2) greater characteristic distinctiveness with no loss of power; (3) reduction in first cost; (4) reduced maintenance; (5) simplification of design and construction; (6) equality of power and efficiency of all light-houses.

To obtain the rapidity of rotation necessary for the lightning lights, it is imperative that some new kind of rotatory carriage should be found. The mercury float mechanical movement devised by Mr. Bourdelles consists in bearing the optic on a bath of mercury, the pressure of which counterbalances the superposed apparatus. A spindle, borne on a pivot, maintains the apparatus in a central position, or, instead of the spindle, horizontal rollers may be employed. The result is great uniformity of speed in combination with a constant of resistance, and this, too, without the introduction of numerous working parts.

#### SUMMERS' DEVICE FOR INSTANTANEOUSLY CHANGING SLIDES.

Fig. 1 is an elevation of the slide device.

Fig. 2 is an elevation of a modification in which the slides are changed by a rotating device.

Figs. 3 and 4 are vertical sections through carrier, showing a magazine for slides.

Figs. 5, 6, and 7 are elevations of carrier, showing horizontal guides.

Mr. Summers says: In carrying out my invention, I preferably employ a vertical grooved guide, *B*, of sufficient height to accommodate three or more lantern slides one above another, the guide being so fitted to the lantern that the middle slide, *x*, of the three is in focus with the lens. Before placing a slide in the vertical guide the former is first put into a grooved frame, *c*<sup>1</sup>, each frame being so shaped as to permit it to

FIG. 1.

drop, without any manipulation at the lantern, into the required position in the grooved guide, *B*. The vertical guide is fitted with a spring, or other catch, *A*, the tongue, *a*<sup>1</sup>, of which normally projects inward, and in such a manner that it prevents any slide passing the middle or focus position until the said catch is operated, when, by the withdrawal of the tongue, *a*<sup>1</sup>, the frame carrying the slide last exposed falls by its own weight into the space, *r*, below, which has been previously cleared. Each grooved frame or slide-carrier is made somewhat less in width at the top

end, as shown on the slide, *c*, at *p*<sup>1</sup>, this difference permitting the tongue of the spring catch, *a*<sup>1</sup>, to engage with the lower part of each slide-carrier as it falls into the focus position, and thus to be retained until the catch is operated, when the slide last exposed will instantaneously disappear into the space *r*, and that above it in the guide as quickly take its place. Upon the catch, *A*, being released, the slide, *x*, as it falls, strikes the lever, *a*<sup>2</sup>, thereby bringing the catch, *a*<sup>1</sup>, into position for engaging with the next slide, *c*.

The slides may be fed into the hopper-like guide either by the operator at the lantern one by one, or a magazine may contain the remainder of a series of slides, and the latter be fed in rotation either by hand or by mechanical means, as, for instance, the grooved guide, *B*, may be made of a length sufficient to carry any number of slides resting one on top of another, or I may place a holder containing the remainder of the series of slides as shown by fig. 3, in which the slides would be placed one

FIG. 2.

behind another, as shown at *L*, the spring, *M*, being provided behind to move them forward to mouth of guide, or the bottom of the holder may be inclined at such an angle as will make the slides have a tendency to move towards the mouth of the grooved guide, *B*, or, again, the holder may be fitted with a lever or catch which, when operated, releases or brings forward a slide. This lever or catch may be either operated by hand or by the weight of the slides falling after they have left the holder, or again to overcome the difficulty of slides stopping at the mouth of grooved guide, and not dropping down through the pressure of slides behind, I may employ an endless band, *v*, at each end, with projections, *d*<sup>1</sup>, working in the groove of the guide and parallel to it. The projections, *d*<sup>1</sup>, would be placed at such distances as would allow the carriers with slides, or the slides, to rest between them; fig. 4 shows one of the grooves fitted with an endless band running over pulleys, *x*, and *x*<sup>1</sup>. A slide rests on the projection, *d*<sup>1</sup>, and another on the projection above; by means of the spring, *M*, a slide is pressed forward to mouth of the grooved guide, *B*, and rests on the projection, *d*<sup>1</sup>, below it. When the catch, *A*, is withdrawn the bottom slides cannot fall without carrying the top slide with them. Thus it has the weight of several slides instead of one to overcome the

FIG. 3.

FIG. 4.

resistance at mouth of grooved guide, while each bottom slide falls out at *v* into a receptacle placed beneath to receive it; or an aperture, *b*<sup>1</sup>, may be provided in the vertical slide-carrier, from which the slide may be removed by hand or mechanically by an endless band as shown by dotted lines, *v*, in fig. 1. The catch, *A*, may be manipulated by the operator at the lantern by the button, *a*<sup>2</sup>, or it may be actuated at a distance by means of electrical, pneumatic, or other suitable mechanical devices applicable to such a purpose as for illustration by means of the electro magnets, *K*, the soft iron, *a*<sup>4</sup>, on the catch, *A*, is attracted by a current passing through the magnets, and the catch is withdrawn.

Or I may employ a horizontal grooved guide, and remove slides by suitable mechanical means, such as an endless band, the same tongue or catch being used as described above to control the actual changing.

By a horizontal guide I mean a similar one to the vertical guide above described, but constructed to change slides across the lantern front in a horizontal direction, as this form would be more readily adapted to the view projecting lanterns at present in use. In my vertical pattern the slides require no power to move them in the guide, as they fall by means of their own weight; but, when the guide is placed in a horizontal position, gravity no longer acts in the direction in which it is required to move slides; I have therefore to apply power to give them the required tendency to move, using a similar means of controlling the actual change. This can be done in a variety of ways by mechanical means, several of which I here describe.

Fig. 5 shows elevation of horizontal carrier, with circle showing position of lantern front, *s*, in correct position for showing slide; *x* is where next slide is to be inserted, and *o* space for each slide to be moved to when changed; *h*<sup>1</sup> is a catch which normally rests in its present position, and when withdrawn, by means of pneumatic or other power, in the direction indicated by the arrow, tends to return again to this position as the spring or elastic attached to it, as shown at *m*<sup>1</sup>, pulls it back in the opposite direction to that in which it has been drawn out, as shown by fig. 6. Instead of a spring or elastic substance being used to draw back this catch, a weight may be used to work the carrier. The

catch, *h*<sup>1</sup>, is withdrawn, a slide is inserted at *x*, and the catch made to fasten on to it, or be placed so that it cannot return without bringing the slide with it. The slides, *s* and *x*, will now have the tendency to move across in the direction of *o*, and will do so when the catch, *f*<sup>1</sup>, is withdrawn. The slide, *s*, is then taken out or allowed to drop at *o*, and the next of the series put in at *x*, either by hand or from a magazine such as shown to the vertical guides which would, in this case, be placed in front of the guide.

Or I may employ an endless band or bands with projections as in the vertical guide, and make same have a tendency to move always in the one direction by mechanical means such as a wound-up spring, or again I may use a long band with projections running along the bottom groove, and hanging down over the ends of the guide, and attach a weight, *w*, to the end at that side of the guide towards which I require slides to move as shown at fig. 7, the same kind of catch, *f*<sup>1</sup>, being used as described above to control the actual changing of slides.

The slides in this case may also be fed in and taken out in a similar manner to the other guide before described; or I may employ a circular carrier which is formed in wheel shape as shown by fig. 2, and is free to revolve on the central bearing, *x*, and clips, frames, or holders, are placed round the circumference to hold any number of slides according to the size of such carrier. This carrier, *m*, is placed in lantern front in such a position as will allow of one slide, *s*, being in focus of the lens, *x*, at one time. For changing the slide, the slide, *o*, and holder is simply fed in at *r*, by the operator or magazine at the lantern, and the carrier turned the correct distance to allow the next holder and slide to come into focus, the same movement passing the previous holder and slide, *r*, out of focus. This carrier turns by means of the weight of the slides being in one arc of its circle, or it may be turned by electrical, pneumatic, or other suitable mechanical means, and is also fitted with the spring catch, *x*, which can either be actuated by hand at the lantern, or by means of the electro magnet, *m*<sup>1</sup>, or any of the devices hereinbefore specified, the object of such catch and devices being to enable the actual changing of slides to be controlled from the platform or at any distance from the lantern. It will be obvious that the catch, *a*<sup>2</sup>, may be operated the same from a distance by pneumatic means or by the use of a flexible cord and pulley.

## THE SALVATION ARMY'S USE FOR THE CAMERA, KINEMATOGRAPH, AND LANTERN IN AUSTRALIA.

A SALVATION ARMY official sends the editor of the *Australian Photographic Review* the following interesting account of the work done under this heading:—

During the past twelve months we have made very marked progress in our photographic, kinematographic, and lantern work generally. At the present time we run three kinematographs, three biennial lanterns and nine phonographs, having a couple of operators always touring the different colonies of the Australasian group. During this time, we have taken some seventy or eighty subjects for the kinematograph, the major portion of them being, of course, scenes illustrating our own particular work. Amongst this number are the usual street scenes, water scenes, and also two or three Maori films that were taken by myself whilst in New Zealand some two months ago.

Besides films, we do all our own lantern-slide making, all of these being taken from life models, and nothing but the "Austral" plates used, as we find them in every way undoubtedly superior to anything else we have tried in lantern plates. We have illustrated lectures for both Commandant and Mrs. Booth, with live-model slides numbering several hundred, and these have been given in all the principal buildings of the colonies, including Town Hall, Sydney, exhibition buildings of Melbourne and Adelaide, and the largest provincial halls of the various inland towns of Australasia. By this medium the social funds of the Army have been largely augmented.

Most of our studio work is done in a very commodious and well-lighted studio, situated at the rear of our Australasian headquarters in Bourke-street, Melbourne, but for subjects with a great number of models we have an extra large studio, 40ft. x 22ft., situated within easy distance of Melbourne.

A scenic artist is continually kept with the brush in his hand, painting the various backgrounds needed for the work, some of the sets of slides needing 30 or 40 grounds.

All our kinematograph films are taken with the Lumière outfit purchased from Baker & Rouse some twelve months ago, and I can safely say no other camera, so far as I have seen or heard, can come within "coo-ee" of the Lumière. It is a beauty, and as sure as the sun.

Staff-Captain Perry, the head of the department, is a lanternist of several years' experience, having travelled almost all over the colonies, including New Zealand and Tasmania, and is well known as a photographer and kinematographist of some repute. He is assisted in the studio work by Lieutenant Rumble, the travelling operators being Staff-Captain Williams and Adjutant Dutton.

During the coming twelve months greater strides than ever will be made, and it is safe in saying that this organization is quite up to date in this work, which will compare favourably with any of its kind in the colonies.

## INTERNATIONAL LANTERN-SLIDE COMPETITION.

The following are the rules and conditions drawn up by the Association Belge de Photographie, which is holding an international competition for lantern slides:—

I.—The competition is divided into four classes:—

1st Class.—Artistic Slides: Landscapes, Inland Scenery, and Marine Subjects.

2nd Class.—Artistic Slides: Figure Subjects, Single-figure Studies, Groups.

3rd Class.—Scientific Photographs.

4th Class.—Architectural.

II.—Competitors must state which class they are entering.

Twelve slides must be sent in for each class; the same slides cannot be entered in two classes.

III.—A Special Jury will judge each class.

IV.—Three prizes will be given in each class: 1st prize, a silver-gilt medal; 2nd, a silver medal; 3rd, a bronze medal.

Should the Jury think it necessary, they will also award an honourable mention.

V.—The size of plates must be  $3\frac{1}{4} \times 3\frac{1}{4}$  inches or  $8\frac{1}{2} \times 10$  cm.

VI.—Each slide must bear the competitor's name, title of picture, also class legibly written on the face of mask.

VII.—The slides will be judged by arc lamp.

VIII.—All packets of slides must be sent in, carriage paid, before October 15, 1899, to Association Belge de Photographie, Palais du Midi, Bruxelles.

IX.—Winners of prizes will be required to leave the slides that have been awarded in the hands of the Society until March 15, 1900. The Association will exhibit them at their Annual Meeting of November and also at the meetings of their seven sections in Belgium.

X.—All slides will be returned, carriage paid, to owners.

XI.—All competitors will be informed of the result of the competition in November.

XII.—Every care on the part of the Association will be taken to preserve the slides; nevertheless, they will not be held responsible for loss of damage to slides sent in.

XIII.—An entry form, duly filled up must be enclosed in each packet.

## LUMINOUS PAINTS.

ARTICLES painted with luminous pigments have now been on the market for some time. These objects then shine in the dark, owing that property to a layer of varnish with which they have been covered, and which contains certain finely powdered substances which have the power of absorbing solar light for a certain time and then re-emitting it. Certain of the sulphides of the alkaline earths possess this quality in a marked degree, and are liable to become luminous by exposure to the electric or to the magnesium light as well as to the sun. Several minerals, such as the diamond and apatite, says a contemporary, are phosphorescent, and it was once believed that they attracted light, just as the magnet attracts iron. Some of the phosphorescent minerals were used a very long time ago by the Chinese for the manufacture of luminous paints, for we read in an old Chinese chronicle that about 1000 years B.C. a wondrous picture was shown to the Emperor of China, and appeared white by day, but by night showed a bull in the proper colours. The bull had been painted with luminous paints, and emitted at night the light it absorbed during the day. In 1878, luminous artificial flowers were shown at the Paris International Exhibition. This was the beginning of the practical utilisation of luminous pigments, and shortly afterwards Balmain, an Englishman, took out a patent for the industrial application of these phosphorescent bodies. In time these came to be used for technical articles, and many others in current use. Chemically they are sulphides of the alkaline earths, especially of baryta, lime, and strontia. These compounds are calcined at high temperatures, and used in a very finely powdered state.

The manufacture is conducted as follows:—Wash oyster shells in hot water, calcine them for half an hour, grind fine, and sift. The fine powder is then interstratified with sulphur in a crucible. The cover of the crucible is then firmly luted on, and the contents are then strongly ignited for an hour. The resulting white powder is ground and sifted and mixed with a varnish composed of Kauri or Zanzibar copal, turpentine, and linseed oil. It is important that the varnish should not contain lead or manganese, because these metals would destroy the phosphorescence. It is a singular fact that chemically pure calcium sulphide is not at all luminous. The presence of traces of impurity is indispensable for producing the phosphorescence. The temperature and duration of the calcination have much influence on the luminosity. Salts of strontium require the lowest temperature, and those of barium the highest temperature and the longest continuance of it. Calcium salts stand midway, and require a temperature of 800° to 900° C. for half an hour. The luminosity and the shade are also affected by the nature of the raw material employed. Thus, barium sulphide, prepared from natural barytes, gives an orange phosphorescence, while, with the artificial sulphide, the colour is greenish. Strontium and sulphur, calcined together below 500° C., give a paint with a yellow phosphorescence, but, if the temperature is higher than that, the phosphorescence is violet. These interesting facts are of great importance in luminous paint-making.

The great enemy of all luminous paints is damp, because it causes the formation of non-luminous sulphhydrates. The surfaces to be painted with a luminous paint should be first coated with some varnish, so as to get a smooth surface. Any irregularities injure the effect of the phosphorescence. Luminous water colours should only be used indoors, and on objects which do not get exposed to damp. Porous bodies must have their pores filled up by the application of a solution of gelatine, and be then thoroughly dried before luminous paint is used on them.

One use of luminous paints is for the name plates at street corners (where there is not a public-house). It is true that in towns well provided with night lights this is unnecessary, but all are not so well off, and luminous paints are most useful for painting up names and other information in halls, staircases, passages, &c., which are often or habitually dark. They are also useful in diving operations, and for painting small objects which are often hunted at night, such as match boxes, door handles, candlesticks, watch cases, &c. In this way they indirectly diminish risk of fire.

Luminous paints are made of all colours, but the luminous base is always sulphide of calcium, and it is mixed with other bodies according to the colour wanted. Red is got by adding red sulphide of arsenic and madder, yellow with barium chromate, green with chrome, and blue with ultramarine or cobalt. In all cases the pigment is diluted with artificial barium sulphate.

"I SAW some very interesting rapid exposures of flashlight explosions recently," says the editor of the *Photo-American*. "The camera was eight feet from the pan whereon the pile of powder was burned, and both shutter and flash were set off at the same moment by bulb and tube. One taken in a five-hundredth of a second was particularly interesting, showing what I think was the yet unburned powder. A series of such pictures would be of great value to those who are called upon for much flashwork, as one can learn how to regulate the charge, how much burns and how much is wasted, thus avoiding more smoke than is necessary, waste and mess from unburned powder all over the floor."

A FLASHLIGHT EXPLOSION.—Again we have to caution our readers about the dangers of making and using flashlight powder. A chemist and photographer employed by the Telegraph Publishing Company, New York City, was compounding a flashlight mixture in the studio in West Forty-second-street, on February 9, when the mixture exploded. The

photographer was the only man in the studio at the time, and he was too badly injured to tell what actually occurred. The report of the explosion could, however, be heard a block. The tenants were badly scared, and so were the occupants of adjoining buildings. The explosion was followed by the sound of breaking glass, the concussion having been so great that it wrecked the glass skylight of the studio. The first person to arrive at the studio found the photographer's clothing ablaze, and that he was severely burnt about the head, arms, and body. He was taken to the New York Hospital, where his condition was said to be serious. The blaze in the building was extinguished without difficulty.—*Scientific American*.

A NEW GASLIGHTING SYSTEM.—A representative of *Industries and Iron* had recently the opportunity of inspecting a new invention in coal-gas lighting, which, though at present not fully worked out, he considers presents all the appearance of interesting possibilities. The process is stated to effect a considerable saving of gas in two directions, viz., a diminution in absolute consumption, and a material augmentation in photometric value per cubic foot of gas passing the meter. The data regarding these claims are not yet fully ascertained, so that at present we can pronounce no opinion as to how far they may be justified. It is only fair to mention, however, that the apparatus employed is of a merely experimental character, and has not been submitted as yet to anything in the nature of expert judgment. The method by which the gas is employed as a lighting agent at the same time presents features so interesting as to be worthy of some interim notice, though we trust to be able shortly to present full details, drawings, and other particulars connected with it. The light itself is of a very unusual and attractive appearance, consisting of a cluster of three or more jets burning downwards. The flame is perfectly homogeneous in colour, resembling rather a short rod of carbon heated to high incandescence than the ordinary gas flame. The principle of the invention is the admixture with the gas of a proportion of atmospheric air, and then compressing the admixture to some five inches water pressure, by means of a small portable accumulator or compressor. The gas jets themselves are tipped with, not spongy but solid, platinum, closely perforated so that the jets are self-igniting. Any patent regarding the employment of platinum in this direction is perhaps questionable, as spongy platinum has long been employed for this purpose. As to the beauty of the light itself there is no question. In artistic appearance and the quality of the light emitted it is able to compete with anything now in use, whether oil, coal gas, acetylene, or electricity. Whether or not its claims to superior economy may be borne out, the light itself will certainly claim attention from its intrinsic merits as an illuminant alone.

NEW USES OF GLASS.—Early in October 1898 a paving company of Lyons, France, began laying on the Rue de la République a piece of pavement of ceramo-crystal, ceramic stone, or devitrified glass. During the months of November and December of 1898, and thus far in January 1899, this pavement has been driven over during all hours of the day and night. It has stood as hard usage as any pavement could be subjected to during that time, and is still in an admirable state of preservation. The glass, or ceramic stone, pavement is laid in the form of blocks, eight inches square, each block containing sixteen parts in the form of checkers. These blocks are so closely fitted together that water cannot pass between them, and the whole pavement looks like one large checker-board. Like all thoroughfares in France, the road-bed slopes gently to the walk on each side. Some of the edges of the checkers have been broken off during their three months' service. United States Consul Covert counted some twenty of them that have been slightly chipped on the edges. It is contended that this does not argue against the value of the material as a pavement, and that any kind of stone would have suffered just as much, or more, in the same time. Mr. Covert visited the Ceramo-Crystal Manufacturing Company's works at the suburban village of Demi-Lune, about six miles from Lyons. The factories cover nearly 8000 square yards of ground. Work is now stopped in them while additions are being made to the buildings in the shape of second stories. In the yards are many tons of broken bottles, which the superintendent told me was their "raw material." On the four sides of a large brick smokestack are specimens of ceramo-crystal for buildings and interior decoration, some of the pieces as smooth as highly polished marble, others being rough, like cut stone, and still others having a surface like common brick. The advantages attributed to this ceramo-crystal by the manufacturers are: As a pavement it has a greater resistance than stone; it is a poor conductor of heat, and ice will not form upon it readily; dirt will not accumulate upon it as easily as upon stone, and it will not retain microbes; it is more durable than stone and just as cheap. The Central Architectural Society of France made a report recently on this ceramic stone. This subject is being discussed in the press and is receiving general consideration. An elaborate and exhaustive article in the *Revue des Deux Mondes* for November treated the question under the heading of "A glass house," the writer asserting that a large house constructed entirely of glass would be an attractive feature of the coming World's Exposition in 1900. He said that glass could be used for tubes, pipes, vats, tiles, smokestacks for factories, and for buildings. Double glass walls in a house would admit of the circulation between them of cold or warm air, thus regulating the temperature. The glass house, or the luminous palace, which it has been decided to build on the grounds of the 1900 Exposition, is now being constructed.

### LANTERN MEMS.

A GIANT projection telescope is the latest invention, and, according to one of the morning papers noted for its "go-aheadness," this wonderful instrument will enable "visitors to view the marvels of the moon as revealed in a picture fifty-two feet in diameter; Mars will be shown twelve feet wide." Of course, every one with only a little knowledge of science has heard of the solar microscopes that were in vogue before the introduction of the oxyhydrogen lime-light and the electric light, but the uncertain nature of our atmosphere and the erratic ways of King Sol have put it out of court for several generations past. How many of the readers of the notice alluded to accepted the announcement as a fact is a problematic matter, but certainly the long-headed would take it more with a spoonful than a "grain of salt."

EVEN given a mirror of six and a half feet in diameter, and weighing three and a half tons, also a telescope nearly 200 feet long, and an object-glass weighing 800 pounds (the diameter is not stated), one cannot help being sceptical about the resulting projection being equal in illumination for 6000 persons to witness, notwithstanding they are "comfortably seated in armchairs, refreshed with cooling drinks." A projection of the sun's disc may be possible, and the moon's surface representation probable, but the image of Mars twelve feet in diameter from its reflected light, if accomplished, will want a lot of heating, if any one is anxious to go one better. I could not, however, but feel somewhat as one feels when reading a story about a person who was pronounced incurable by so many physicians, and had such all-gone feelings until he took Mr. Blank's mixture or pills, and so I did, what most sensible people do with such narratives, read the final paragraph. This, I think, speaks for itself. It is so important, it must have a par all to itself.

"WHEN the weather is cloudy, the telescope will project on the screen photographic images of the heavenly bodies." Photographic, mind you, and, if photographic, what about the illuminant? I do not think there is much risk in prophesying that the weather will always be cloudy, for I should like to realise the wonderful brilliancy of "the planets, stars, comets, and nebulae" that can be "turned on one after the other." I only wish I had sufficient inventive genius to have conceived this idea, for I should have known how to realise it when an electric arc lamp was available, if not to conceal up my

sleeve as the conjurers do, at any rate to so place it in the telescope tube that it faithfully performed the work of the sun. What a glorious opportunity for the mechanical slide-painter to show "naturally" all the wonders of the heavens, including the cleverly contrived solar system slide that form part of the commercial six-guinea astronomical set.

THE public like being gulled, if you can only manage it in a way to entertain them, and can give half a reason for doing so, especially if they go away *instructed*. If everybody told the truth, there would be few fortunes made, and, if facts only were palatable, fifty per cent. of the inhabitants of this universe would cease to be pleased with themselves. I have, in my experience, known of people who told "fairy tales" respecting certain operations or apparatus so often that they in the end believed in what they said themselves, and were quite shocked when some one suggested the statements were a slight exaggeration.

GOING from theories to practice, one is pleased to be able to report the satisfactory progress of such a society as the British Astronomical Association, which mainly consists of amateur astronomers, who have the reputation of being workers as well as talkers. The annual *soirée* was recently held at the Zion College, and in the intervals between the address a number of interesting objects and astronomical instruments were on exhibition, while music was discoursed by a good band.

THE addresses were illustrated by some beautiful photographs of the moon taken direct, and the photographic value of records was shown by the illustrations to the address, "On Observations of Jupiter's Satellites," by Captain P. B. Molesworth, R.E., F.R.A.S. The other address was by Mr. A. C. D. Crommelin, F.R.A.S., on the "Photography of Comets," Mr. Walter Goodacre, F.R.A.S., having explained the photographs of "The Moon."

IN my reference to Mr. Lewis Wright's demonstration at the Quekett Club I scarcely did full justice to his excellent projections with the lantern microscope. I find that some of the objects were magnified to 6000 diameters with the lime light used as the illuminant, and I understand that with the electric arc lamp, using fifteen ampères of current, the definition of objects magnified 10,000 times, is all that can be expected, and even with the lime light, is satisfactory if an opera-glass is used by the audience to see the details. An "oil lens" the lecturer has (about one-seventh) holds out quite sharp up to 11,000 diameters. It will be useful for lanternists to know that such excellent results are obtained with the lantern microscope, while the limelight jet in the cases referred to has a nipple of one-sixteenth of an inch only, for Mr. Lewis Wright is of opinion that more is not much use with projection microscopes, as only the central spot is serviceable with powers over 1000, and lower powers do not require more.

G. R. BAKER.

## A FEW ESSENTIALS TO SUCCESS IN LIMELIGHT PROJECTION.

It is now about seventeen years since it may be said that steady progress has been made in limelight projection, for as far back as the year 1883 several gentlemen commenced to study minutely not only the most advantageous methods for utilising the limelight in connexion with lantern projection, but at the same time experimented largely in the endeavour to overcome any liability of accidents with the means employed at this early date.

At the date mentioned, although in America gas bags had been practically discarded for bottles in which the gas was compressed, in this country they were still being largely employed, but from this date may be said to commence a new era in connexion with limelight projection, because there were not wanting those who saw clearly the immense advantages underlying the use of gases in bottles or cylinders, and that they were certain within a few years to make the use of gas bags a thing of the past.

With the advent of compressed gases in cylinders limelight workers at once saw they had a fresh power placed in their hands in respect of one of its chief essentials, viz., unlimited pressure, and it was not long before one of the earliest difficulties in connexion with the use of compressed gas, viz., the difficulty of delivering the gas to the jet at an equal steady pressure, was satisfactorily overcome. At first this difficulty was so great that many of the most successful limelight workers considered that the light never could be satisfactorily worked, but in the year 1884 the problem was solved by an ingenious form of regulator, which, although large in size and costly to manufacture, gave abundant evidence that, before long, the delivery of compressed gas from highly charged cylinders would be easily accomplished. This early form of governor was soon followed by smaller and less costly patterns of regulators, which, being rapidly placed upon the market, sealed the doom of the good old gas bag, and so at once got rid of very much that detracted from the ease and comfort of limelight working.

In nearly all the early forms of gas-governors or regulators indiarubber in some shape or other was employed, and especially was this the case in what has proved to be perhaps one of the best forms of regulators ever placed upon the market, viz., the original Clarkson instrument, in which the gas is admitted to a small indiarubber bag, which, when distended, entirely cuts off any more gas from the nozzle of the cylinder. This form of regulator is still greatly appreciated by many clever operators, its one drawback being a liability, through rough usage, to leak; but, when properly taken care of, there is no doubt it proved a most valuable essential in limelight projection. In nearly all the earlier forms of regulators provision was made for increase of pressure if desired; but, in contrast to the pressure hitherto employed by the use of gas bags, which, for a good mixing jet, was generally somewhere about twelve or fourteen inches water-gauge pressure, all regulators had a considerable margin to spare; and, when it is borne in mind that a pressure of twelve inches means about seven ounces of weight per square inch, and that the early form of regulator was loaded to one and a half pounds pressure or thereabouts, it is easily seen that the road was soon thrown wide open for the utilisation of more powerful jets than were at first employed.

For ordinary lantern-slide projection in what may be termed a public form, i.e., in large halls where fifteen to twenty-foot discs are required, the mixing jet has always been looked upon as an essential part of a first-class lantern outfit, and, with the improvements connected with the use of compressed gas, experimenters soon gave their attention to the best form of jets to employ, more particularly in relation to the size of aperture that yielded the best results with the increased pressure they now were enabled to bring to their aid. The outcome of these experiments we now see in the numerous new forms of jets which have during the last few years been placed upon the market. Ten years ago a jet that would yield an honest thousand-candle-power light was looked upon as a good thing in the way of radiants, but now there are jets claiming to yield nearly double that power. With regard to the best aperture to employ for ordinary limelight projection, such as where merely lantern slides are concerned, it should be borne in mind that it by no means follows that an aperture such as the seventeenth of an inch, frequently found in jets more particularly designed for a cinematograph, would be the most useful, for, in the former case, there is no actual need for such a powerful radiant; and, further, a most important essential in limelight work such as ordinary lecture purposes requires is a strictly comfortable working lantern, for it must be borne in mind that with more open bores in the nipples of the jet more gas is burned, with, of course, a very much greater increase of heat; therefore the most comfortable aperture to employ in cases where merely ordinary lantern slides are concerned, and where the discs are not required to be beyond, say, fifteen feet, will be about the twenty-fifth of an inch. Any well-made jet in which the mixing chamber is of fair dimensions will, if properly packed and designed, yield easily up to a thousand-candle-power light without pressing beyond the silent working point.

It will be at once admitted that a roaring or whistling jet should never be countenanced for a single moment. In the early days of the mixing jet this trouble was more seen than in the jets of later-day manufacture,

and the cure was soon found to lie in the proper form of packing used in the mixing chamber.

With gas bags there was, of course, a limit to the extent of packing; that could be placed in a jet; but, with the increased pressure from cylinders, larger chambers are made, and these are packed to their last extremity, the aim being to thoroughly mix the gases and to secure a silent light in the jet when under high pressure. The hissing or whistling of a mixing jet is nearly always cured by inserting a number of brass rings, upon which are placed perforated discs of tin; this never fails to yield a good result under an increase of pressure; but, in the newer form of jets, in which the shape of the mixing chamber partakes somewhat of the form of a torpedo, the packing is composed of different material, such as pumice powder and asbestos; and in jets of this class the apertures are larger, more gas is consumed, greater heat generated, and they are intended for cinematographic projection more than for ordinary lantern purposes.

The employment of jets with large apertures calls for special provision in the way of longer-focus condensers, and, if care be not taken in this respect, it will soon become evident by the destruction they will work when used in conjunction with the usual short-focus condenser found in nearly all the stock lanterns of the present day. The writer has over and over again attended limelight exhibitions where this was painfully evident in the cracking of condensers, in one instance no less than three condensers giving way one after another within half an hour. A modern powerful jet, with an aperture of, say, the fifteenth or seventeenth of an inch, should never be employed upon a condenser of less than four-and-a-half-inch focus. No doubt the temptation to use large bores in a jet is very great when an operator is called upon to throw a bright disc from, say, the back of a hall, and long-focus objectives have to be used; and, as every one knows, the longer-focus objective requires the jet being brought closer to the condenser, thereby increasing the risk of fracturing the same. It therefore follows that, if these larger bores are to be employed with any degree of comfort, it is essential that the optical arrangements of the lantern should be such as permit of their being used not only in comfort but in safety.

During recent years the practice of throwing as large a disc as possible from a medium or short distance was, no doubt, fostered by the short-focus objectives supplied with most lanterns; but clever operators, who knew the objectionable features connected with working in the middle of an audience, never countenanced this, and prefer invariably to work whenever possible behind the heads of the audience. Of course, this means long-focus condensers and objectives, and not, as many imagine, merely long-focus objectives only. One of the earliest authorities in limelight projection drew attention to the importance of the employment of long-focus condensers in conjunction with long-focus objectives so far back as the year 1884, for in that year Mr. G. R. Baker, in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, by means of a clever diagram, showed how important it was that the entire optical system of a lantern should be such as I have stated. An ordinary short-focus condenser will not feed, say, a twelve-inch objective properly, and in all cases where such long-focus objectives have to be used longer-focus condensers ought to be provided.

In former years nothing like the same amount of light was yielded by means of gas bags as is obtained now by means of cylinders; but it is well known that many first-class jets are never employed to their best capacity in modern lamps simply by reason of the failure to use them in conjunction with other important essentials. A striking example of this recently came under the writer's observation, where a modern jet capable of yielding a very high candle power was being used in conjunction with a governor that was quite inadequate to yield anything like results. The jet in question was expressly stated to require a pressure of fifteen pounds per square inch; but, in the case referred to, one which yielded only about two and a half pounds was being employed.

In cases where jets of this description are concerned it is, perhaps, advisable to discard the use of regulators entirely, and fall back upon a fine adjustment valve, by which means any amount of pressure may be obtained. When, however, these fine adjustment valves are used on a cylinder, there is a strong liability for the light to go down, by reason of the constantly reducing pressure on the cylinder. In cinematographic work this is not of so much importance, because, prior to every new film, the jets can be run up to their very utmost capacity, and the intensity of light will continue sufficiently for any one or two films being run through; but for lecture purposes, especially where single lanterns are in use, the light is not kept nearly so steady with these taps as when good regulators are employed.

The difficulty of using these fine adjustment valves on a full cylinder is somewhat greater also than is the case when cylinders of large capacity are somewhat well run down, for the merest hairbreadth of movement will probably bring on unequal mixture of gas in the chamber, so that it takes an experienced hand to employ them; there is no doubt, however, that, when a heavily packed jet is required to yield its best, a set of fine adjustment taps are handy things to have at hand.

Where regulators are used the utmost steadiness can be got out of a jet, and there is no doubt that the addition of screw-down valves to an ordinary tap jet is a great advantage over the old form of jet in which only ordinary taps are provided.

The addition of these new screw-down taps gives also an additional

power and facility in regulating the flow of the gas, and permits not only of the nicest possible adjustments, but enables the gases being turned down or entirely cut off by means of the ordinary wing taps without disturbing the fine adjustments derived from the screw-down; and this permits of all adjustments being made prior to the commencement of a lecture, which is an important essential and a great comfort.

A. T. NEWTON.

### TESTING ACETYLENE GENERATORS.

There are four villages in this country, says the *Scientific American*, lighted in part or entirely by acetylene gas, and a number of stores, factories, and hotels have installed plants having a capacity of about two hundred lights each; but, nevertheless, the principal development to-day is with that type of generator that is adapted and intended for the lighting of such places as dwelling-houses, small stores, offices, or shops, in localities where the ordinary city gas is not to be had or is supplied at an excessive price.

Up to the present, the development in generator design and construction has rather tended toward multiplicity, rendered possible by the simplicity with which the gas can be generated, and inventors find that it requires very little ingenuity to devise a satisfactory apparatus for the purpose.

This multiplicity of apparatus is instructive as a study, but when they are actually to be introduced into communities where their faulty action, especially in the hands of careless or ignorant persons, may cause loss of life or property, the idea at once suggests itself, How are we to know whether any generator of the sort offered for sale is safe?

To this question there is but one answer, Test it, have some one else test it, or inspect it at some place where the generator has been in use for a long time. There are other considerations to be reckoned upon than the simple possibility of the apparatus being able to supply gas. Among these may be mentioned the possibility of the gas igniting through the generation of excessive heat in a generator which contains some air, and consequent explosion of the apparatus, although this is liable to occur only in the drip or dip types. Gas may escape into the generator room and be accidentally ignited. The apparatus may be so made that emptying or charging it fills the apparatus with too much air—a fact which soon becomes evident when the careless or ignorant operator brings a flame near it. Deposits of lime, tar, and water in the house pipes caused by lack of filters and condensers, too much heating or violent generation, or an over-production of gas may burst the apparatus or blow out the seals and fill the neighbourhood with an evil-smelling gas. Many other inconveniences may be noted, but these are sufficient to show how important it is to have the apparatus tested or a satisfactory assurance that this has been done by competent persons.

### LIFE-SIZE ENLARGEMENTS.

#### I.

The production of life-size enlargements is frequently looked upon by a large number of professional photographers as a feat requiring special skill and the possession of plant which only a few expert enlargers have at their command, and this belief has, doubtless, led to the practice adopted by a good many professional photographers of intrusting orders of any special dimensions to certain trade firms who cater more especially for this particular class of work. The outcome of this is that many professionals are in reality simply giving away a highly remunerative branch of photography, and one which is at the same time by no means beyond their skill to personally undertake as well as accomplish most satisfactorily.

In speaking of life-size enlargements, I wish it to be distinctly understood that I do not desire any of my readers to imagine that such enlargements must necessarily be of the portraiture class, for there is a very much wider scope in what may be termed commercial photography, into which enlargements enter and form a very important and remunerative branch of a professional's business.

By the term "life size" I include all exceptionally large-size pictures, ranging up to, say, six or eight feet in length, and it is these specially large sizes that confer upon any one taking an interest in this special class of work so much pride and pleasure when they come to look upon the results they have turned out.

As to the difficulty of undertaking work of this description, it need not for a single moment give any concern to a really competent and practical photographer. No doubt in photography, like many other undertakings, there are to be found those workers whose ideas never seem to soar above the "puny," and who rest content with plodding away, day after day and year after year, with the modest half or whole-plate sizes of pictures, and who rarely trouble themselves in their portraiture beyond the time-honoured cabinet. To these the making of a six-foot enlargement does, no doubt, appear a "big job" and one quite beyond their power of undertaking, and so this class of work, which is in reality by no means difficult of accomplishment, drifts into the hands of specialists who know a good thing when it comes their way.

Then, again, there are to be found those workers who are not without the

inclination of undertaking such large work, but are deterred from doing so by reason of the erroneous belief that it necessitates the possession of not only special, but, at the same time, costly apparatus.

I shall endeavour, first, to combat this opinion, and show that in reality the production of large-sized enlargements does not require any costly introduction of special plant or facilities that are not in nearly every instance within the power of any professional photographer to command.

Firstly, I think no one will gainsay the statement that all photographers have at their command an ordinary room in which one window is found, and which, by the exercise of the merest elementary knowledge of carpentering, they can transform into a dark chamber by simply fitting an inner frame, lined with brown paper, in one portion of which is cut out an aperture of sufficient size to illuminate any ordinary negative.

A brief description of the room in which I regularly turn out these large-size pictures may, however, tend to guide those of my readers who would care to undertake this work.

The room that I have utilised as an enlarging chamber is seventeen feet square, and has one window, facing north, six feet six inches by three feet six inches wide. This window has ordinary wooden folding shutters, but these are not cut or tampered with in any way. The chamber is made absolutely dark by inserting an inner lower and an inner upper frame that fit the upper and lower sashes. These are covered with two thicknesses of stout brown paper, and it only takes a second or two of time to insert them against the window sashes when the room has to be converted into a darkened chamber for the purpose of enlarging.

In the lower top left-hand corner of the bottom sash a square opening has been cut out sufficiently large to allow light to pass through the largest negative required for enlargement, and this square aperture has four old worsted stockings tacked along the edges of the opening, the use or purpose of which is to provide a pad that will exclude all light from entering the room from the cut-out aperture of the screen when the rear of the camera that carries the negative to be enlarged is pushed up against the old stockings.

This simple contrivance is most effectual in the keeping out of any strong light, and dispenses with any costly and less effective system of wooden grooves that ever were invented or recommended by namby-pamby workers.

Against the inner surface of the glass pane in the window I place the focussing screen of my 15×12 camera, which is held in position by a couple of wooden pegs held as buttons by means of a round-headed small nail.

The expense of so turning an ordinary room into the very best dark chamber need not exceed one shilling, for the frames can be joined together by any one possessed of the slightest knowledge of carpentry.

To hold the negative in position in front of the diffusing screen (the ground glass), a rough carrier is provided that slips into the grooves of the back of the camera just like the dark slide; this is easily made out of any flat piece of board and need only cost a copper or two, the swinging frame that carries the ground glass being turned over the top of the front extension 15×12 camera, that I employ for holding all-sized negatives. Of course any smaller-size camera could be utilised for work up to the extent of its capabilities, in which case the cut-out aperture in the lower screen must be made to suit such camera.

In placing the 15×12 camera carrying the negative to be enlarged in position in front of the cut-out aperture I use my ordinary studio stand, that is capable of being raised or lowered to the exact height of the stockings, the camera is then pushed firmly against these pads, and all the arrangements, so far as holding the negative *in situ*, are complete at a cost so trifling as to be outside the pale of consideration.

Any one reading some of the treatises that are from time to time written upon enlarging would, no doubt, be frightened at the bare idea of having to provide easels, and runners, and exposing platforms, and a lot of other absolutely useless provisions on this class of work; and no doubt this sort of thing, to a great extent, deters many keen workers from doing their own enlargements. In practical photography it is wonderful how little is absolutely required for turning out the very best class of work. Luxuries, no doubt, do bulk largely in the practice of photography, but, as a general rule, they are of little practical value; the simpler all apparatus is the better, and this I find holds good in the making of large-sized enlargements. It may surprise my readers to be told that in my regular work I dispense entirely with easels, platforms, tramways, and all such accessories, and never find it necessary to employ any other easel than an old kitchen table, whilst for the exposing board I invariably use the trough or large wooden dish that I develop and wash the large pictures in.

When I first took to making these large-sized enlargements, like other workers I had a hazy notion about the need of so many large-sized dishes that I began to sum up the cost, but, setting "a stout heart, to a stye brae," as we say in Scotland, I just faced the difficulty, and a very little close consideration showed me that it was but a trifling matter after all. My first experience of the making of such large-sized pictures was gained many years ago when I saw and took part in the production of large plans and enlargements in one of the leading ship-building yards on the Clyde. Here money was never grudged and the head draftsman and photographer fitted up a costly slate tank with no end of fixings and

water sprays, all very nice, no doubt, but these were luxuries, and in point of fact did not conduce to the turning out of any better results than was possible by the employment of very much less costly means.

It is my good luck to live in close vicinity to a timber or saw mill, and so, when I made up my mind to go into the big in connexion with enlargements, I paid a visit to the foreman of the mill, and, handing him a small specification of the boards necessary for a nine feet wooden dish, I asked him his lowest price for rough undressed boards, cut accurately to sizes given. In ten minutes' time the wood was cut, a few hours after, with the aid of brass nails, it was joined together at home, and the same night, by the aid of the melting of about three pounds of paraffin and a good lot of resin, I was enabled to look with pride and satisfaction upon my effort. In providing the wood it is best not to have it dressed, but on the contrary in the rough condition in which it comes through the mill; in this state the surface is better adapted for holding the wax and resin, and, if a plentiful supply of these ingredients is used along the seams and sides, it will be bottled tight and remain so as long as such is carefully used, and, should it at some time receive rough treatment and show signs of leaking, a hot poker applied to the wax will soon make it right again.

A good sized dish is a great comfort, for it has to do duty not only in development and washing, but likewise for holding the sensitive paper *in situ* during exposure.

The method I adopt is as follows: The table is carefully placed into a position right opposite the lens, and, by seeing that the feet are placed truly against the seams of the boarding of the floor of the room, it is found to be just in the right position parallel with the negative. The large wooden dish is then reared up on its side on the table, care being observed that it is at equal distances at the ends from the side of the table; by this simple means the paper is in true position at both top and bottom and sides, and no distortion is permitted to occur.

The dish is held firmly in this position by nailing guy rods from its outer sides to the floor; when this is done, it is immovable. Of course, before these binding rods are applied, the distance and size of the picture as well as the rough adjustment of focus have been previously made with the dish held temporarily in position. A worker after three or four times having used his apparatus for such large work will become quite accustomed to the distances at which to place his lens from the negative and his sensitive paper from the lens, and little or no delay or trouble will be experienced in placing each of the primary factors in almost their exact position. It practically amounts to a mere matter of having experience with the tools any one is accustomed to use.

The sensitive material for this work is obtained now from the makers in long bands, and in such an exquisite state of perfection that no trouble in this respect need be for a moment dreamt of. It is simply marvellous to what a state of perfection these bromide papers have in recent years been brought.

There is an old saying that a photographer never loses a large plate, and, doubtless, this is to a certain extent attributable to the extra thought and care displayed when large sizes are being manipulated; the same remark holds good in exposing large sheets of bromide paper. Mistakes somehow or other don't occur, at least not with the writer. But then pilot exposures are always previously made, and the same developing solution used. A strip of paper which receives three different periods of time is first exposed, and the development of this never fails to yield or show the best time to give to the full piece.

With dense negatives very long exposures have to be given, running sometimes into hours, but any practical photographer will at once understand that there is no other or true guide to a correct exposure than by running a pilot under entirely similar conditions as regards light and development, and any nonsense that may have been advised as to timing by means of actinometers should be treated with contempt.

In exposing large surfaces of bromide paper for enlarging, the appearance of the image on the surface of the paper cannot be relied upon either as any guide to timing, the only true course is *piloting*, and some consideration must be given to running the test paper over the densest as well as the thinnest portion of the negative.

With some negatives it is strongly advisable to submit the same to a what may be termed printing test, before attempting to utilise them for extreme enlarging. This printing test may take the form of ordinary silver printing, during which any peculiarity should be carefully noted, and, if this is found to require a certain amount of dodging by shielding or such like means, it is a valuable guide to an operator working in a darkened chamber, where he can with ease shield off any desired portion of the picture as was gathered from the test print.

Vignetting is easily performed by placing between the lens and the sensitive material suitable cut-out masks held in the proper position in front of the lens.

By employing a yellow glass in the cap of the lens the paper is easily placed in its proper position to receive the image after the final focussing has been adjusted on a large sheet of white paper.

The best lens to employ must depend upon the size of negative as well as the amount of enlargement that has to be produced. I use both landscape and rapid rectilinear combinations according to circumstances.

The chief factor in success lies in correctly timing the exposure to suit the developer employed, and the best developer in my opinion is ferrous

oxalate, simply by reason of the power a worker has in gaining density by using an old sample of developer.

If, however, any one can depend entirely upon his exposures being right with the changing light that often occurs during the long time necessary, then metol and a dash of hydroquinone is a most tempting formula to use, simply on account of its cleanliness.

In developing, a large supply of solution is absolutely essential, otherwise unequal development will most certainly cause trouble; but, with the solution carefully compounded and a large camel's-hair brush being at hand, a little practice will get rid of all funk, which at this stage is liable to possess an inexperienced hand, and beautifully even results be achieved.

Of course, in large work of this kind, the services of one or more assistants is necessary; but the developing, fixing, washing, and drying is all accomplished with the aid of the dish, without removing or handling the large prints while wet. In drying, the dish is reared on end and all water run off. When this is accomplished, the print is gently lifted and tacked, with a widish margin, to the sides of the dish; this will enable air to play all around it, and in a few hours it will be dry and ready for removal.

It stands to reason that only extremely sharp and suitable negatives are of any use for being used in such large sizes, and, where it is known beforehand that enlargements are likely to be required, it is a good practice to specially provide for such in all negatives to be so used.

The finishing in black and white is an important part of enlarging, to which I hope to refer in a future article.

The mere enlarging, however, is by no means a difficult operation when gone about systematically, and this branch of work is certainly highly remunerative and one which never fails to command satisfaction.

A. SCOTT.

## PHOTO CYCLING.

At the last monthly meeting of the Blairgowrie and District Photographic Association Mr. John B. MacLachlan gave a paper on "Photo-cycling." Mr. MacLachlan is a cyclist of many years' standing, having been one of the founders of the Blairgowrie Bicycle Club in 1884, and, being Vice-President and one of the originators of the Photographic Association, his paper was listened to with interest. After pointing out the suitability of cycling for the photographer and photography for the cyclist, he gave some personal experiences of the delights of a combination of the two pastimes. Speaking practically, he said, "the cycle might be either a roadster or a light roadster according to the weight of the riders; but it is better to err on the side of too much weight than too little, as a rider may wish to carry a half-plate or even a whole-plate for some distance to secure a desired picture, and this luggage, if the cycle is too light, might with disastrous results, put a strain on the frame it was not intended to withstand. Happily the craze for featherweight machines is on the decrease, and the cyclist—be he photographer or not—recognised that a pound or two extra weight and stability was better than a light machine with 'give' in the frame, the loss of power on the latter more than counterbalancing the extra weight on the former. If a first-class new machine was too expensive, get a cycling friend's advice and buy a good second-hand one. Many a time we may have to go out photographing when the roads are not in apple pie order and mud reigns supreme; if we follow the low-toned, leaden-sky cult, we will want to go out frequently when the roads are distinctly bad from a vehicular point of view, and the moral is obvious. Do not have a machine without a gear case and good, broad mud-guards of sufficient length; many of the present-day mud-guards are too short and too narrow for practical purposes."

All things considered, he favoured a quarter-plate-size camera for photo-cycling. This size was not too heavy, it gave a popular size of print, while in many cases it could be used for making lantern slides by contact. Another and very important matter was that, if one was using plates, these could be bought in almost any town, in this size and at almost any speed. The camera that might fulfil all the requirements of the photo-cyclist had not yet been met with, but it would require to be compact so as to be easily carried awheel; it should be self-contained, collapsible and have double extension, suitable for long-focus and W.A. lenses, it should have a rising and falling front, a swing back (swinging from the centre), and also be available for hand or stand with scale focussing and good finders. If, in addition, it was fitted for glass plates (in dark slides for preference) for work near home and also for roller films, for long runs, we would have a camera very near the ideal. There is also another requisite, and with most of us a very important one, the price must be reasonable. He still held the belief that no place was so well suited for carrying the camera as the rider's back. A quarter-plate was not a heavy weight, and, if properly packed in a suitable knapsack, should be little trouble. On the rider's back it sustained as little vibration as possible, and all who have done any photo cycling knew how easy it was to secure an abundant crop of pinholes, mostly caused by dust, &c., coming in contact with the plate. Of course, in theory there should be no dust there, but in practice the fact remains that there always was some dust on the camera, and with the perversity of inanimate things the least persuasion transferred it to the sensitive films. If the knapsack is made with a cane back, that is, strips of cane sewed to the back with about 1½ inches between each strip, there

is a circulation of air between the knapsack and the rider's back that prevents perspiration; or, again, if the straps supporting the knapsack are sewed on a short distance from the top, the knapsack only touches the rider's back at the bottom, the top being tilted out, and this small pressure is less likely to cause the rider to perspire than a flat surface close to the back. The shoulder straps should be broad, and should be web where they cross the shoulder; the straps should be rounded where they come under the armpits.

After the beginner had so far mastered cycle and camera, the essayist's advice was to adopt one special branch of study and devote the greater part of one's attention to it until it was mastered.

#### RENOVATION OF LANTERN SLIDES.

At the close of the lantern season, doubtless, there are many private individuals, as well as large commercial houses engaged in the lantern trade, who will be gathering their stock of slides together, and replacing those which have suffered by reason of the season's wear and tear. This may mean new cover glasses where they have been fractured, and the rebinding of a very large number that have been heavily run upon during the past season.

In these minor details there is but little skill required, and such renovation can generally be accomplished during the spare moments at an assistant's disposal. But there are other cases in which the renovation of lantern slides forms a most important part of the economy in the lantern trade, and by means of which many old slides may be caused to look almost as good as new.

That lantern slides do deteriorate sadly through the wear and tear they undergo is well known, and many a fine old set of collodion and albumen slides, as well as the more modern productions in gelatine, are all liable to suffer from various causes.

Not long ago, a very fine set of Continental slides, made by Ferrier, of Paris, was brought to the writer, that had, by reason of being stored away in a damp cellar, contracted a number of opaque spots something like mildew, and which, when looked at cursorily, seemed to be sadly deteriorated. These damp or mildew spots were very prominent in the skies, and were so bad as to show up strongly when such were projected on the screen. The slides in question were fine specimens of an albumen slide, and as such were justly appreciated, and their owner was somewhat anxious to know if nothing could be done towards removing these spots and renovating the entire slides to something like their original brilliancy.

On examination, the spots were found to be in the extremely fine film of albumen, or, in other words, the marks were not upon the surface; and, although these spots were not noticeable upon those parts of the picture where the silver was reduced, they were objectionable in the clear sky portions.

Now, in nearly all slides made many years ago by means of albumen, the sky portion of the picture is represented by bare glass, and any spot or eyesore on such parts shows up very badly when the picture is magnified upon the screen.

To remove these marks of mildew, the slides were first treated to a warming or heating operation, and their surfaces were gently rubbed with a pad of cotton-wool steeped in turpentine, to which a very little Canada balsam had been added. This wash improved the general appearance of the slides so far as their surfaces were concerned, and got rid of what appeared to be a superficial deposit or slight fog, which evidently had been contracted by damp or the sweating of the slides in the lantern; but rubbing with this solution had no effect in removing the spots of mildew, which were deeply rooted in the film in the sky portion, and the puzzle was how were such to be got rid of.

The slides being made of albumen, it was found that, on such being treated with various solutions in which water was present, a distinct cloudiness was produced in the parts where local reduction was attempted. All such solutions were therefore at once discarded, and it at once became evident that, if these spots in the skies were to be got rid of, the knife or scalpel would require to be used.

The slides in question were largely composed of street scenes and important edifices in Paris and other Continental cities, and in nearly every instance spires and suchlike objects projected over the sky line.

To many the cutting out of an entire sky portion of a lantern slide might seem a difficult and delicate operation, but with a little practice it is very easily performed indeed, and, in cases where the slides are made by means of collodion or albumen, the film being so extremely thin, all that is wanted is a little courage, a good eye and steady hand, and the proper tool to use.

As to the vast improvements that can be effected upon slides by such treatment there can be no doubt, and, with thought and care, old slides can be brightened up and made to look as good as new.

A steady retouching desk is required, and any one going to undertake this operation should first of all provide a little tool that process-block makers employ for cutting out fine lines in their resist. Any one can make such a tool for himself, and such will be found useful for other purposes.

This little tool is simply a medium-sized knitting needle, the end of which is ground down to an extremely fine chisel point, first by rubbing it vigorously on sandstone, and then finishing off on a finer stone employed for sharpening knives. When a nice sharp cutting point has been acquired, let the faulty slide be placed upon the retouching desk, and without any fear or hesitation an operator should proceed to cut away all along the sky outline. This may mean tracing along house-tops, chimney-pots, church steeples, &c.; but, after a minute or two's working, a feeling of pleasure will most certainly be experienced when it is seen what a vast amount of improvement is being effected, and in ten minutes to a quarter of an hour the whole sky portion is easily removed.

Now, it has been stated that in nearly every instance these old albumen slides were composed of clear glass in the skies, and therefore no atmospheric effects are tampered with in such a treatment; but, in these days of severe criticism, a bald white sky is almost certain to be objected to in a lantern slide, although there are those to be found who are bold enough to advocate a clean white sky in a slide in preference to the dirty mud that is trotted out nowadays and made to do duty for sky effects.

However, the first step towards success has been achieved by the removal of the spots and eyesores from the sky, and, if any one has a subject into which it is desired to add a suitable sky, the matter is quite easily performed in the following manner.

Now, there are several ways of adding skies to lantern-slide pictures, but in the case we are dealing with, there being no sensitive material in the slide itself, it stands to reason that a special treatment which is suitable to this case must be resorted to, and either of the following methods can be made to work wonderfully well.

If the operator knows anything about tinting lantern slides by means of oil pigments, the easiest and most expeditious method is to apply just a *souppçon* of Payne's grey or Chinese white to the cut-out portion, and, by means of the forefinger, blend the oil pigment into the semblance of clouds; this is quite effective, and a clever colourist can work up delightful atmospheric effects by such means. On the other hand, recourse may be had to printing a sky on the cover glass. If this method be selected, let a good sky negative be provided—one that is not too heavy for a sunlit subject—and, by placing a lantern plate in contact, expose and develop the same, so as to produce a bold, vigorous impression of clouds over the entire surface of the lantern plate. After being dried, the cloud positive is brought in contact with the slide, and the portions of the positive sky cover glass that are seen to overlap the image of the slide are carefully noted and marked at the edges of the glass. The positive cover glass is then steeped in clean cold water, and, when quite wetted through to the back of the glass, a solution of ferricyanide of potassium and hypo is applied by means of a broad camel's-hair brush. A very few minutes will suffice to remove any deposit of silver from those parts which will overlap the image of the slide, and by means of a weak solution of this reducer the sky portion may be dodged up and improved greatly with a little practice.

By this means excellent skies are produced. When the work is carefully performed, and the slide bound up, no one would credit the amount of improvement that has been effected by this method of renovation.

In many instances, where deterioration is only on the surface, the simple action of applying a coating of varnish will brighten up a slide wonderfully also.

It has been said that, in the case of collodion and albumen slides, the film being so thin, the cutting away of the sky portion is hardly observable, but with gelatine, where the films are thicker, the outline is more apt to be seen. In practice, however, a gelatine slide is quite as easily doctored as a collodion or an albumen one, and I possess dozens of such that are invariably admired when thrown upon the screen, and which no one is able to detect have been subjected to the treatment referred to.

It only wants the proper tool, a steady hand, and a fair amount of courage, and any one possessed of these essentials should not hesitate to cut out a faulty sky and print in another.

T. N. ARMSTRONG.

#### THE DIFFUSION OF LIGHT THROUGH WINDOWS.

Some years ago the Boston Manufacturers' Mutual Fire Insurance Company experimented with various forms of glass in order to arrive at the best means for diffusing light through windows and skylights in mills, factories, &c. Prismatic, corrugated, rough, waved, and ribbed glasses were tried, but it was found that the most uniform diffusion of light was derived from simple ribbed glass in true curves, inverse and obverse, and having twenty-one ribs to the inch.

Since the above tests were made, the subject has been further investigated by Mr. C. L. Norton, and the results published in a circular just issued by the insurance company mentioned above.

Mr. Norton was decidedly doubtful regarding the assertion that more light was admitted into a room when glazed with corrugated glass than when glazed with plain glass. His experiments, however, have clearly shown that at the rear wall of a room twenty-five feet deep the intensity of the light was increased three times by substituting ribbed glass for plain. A similar increase is found on the side walls and ceilings, but on the floor there is a distinct loss near the window. Mr. Norton explains

this effect as follows: "The light entering through a window comes for the most part from the sky, and has therefore a general downward direction, varying with the time and position. Hence the position of the room which receives the most light ordinarily is the floor near the windows; but, if we interpose in this downward beam of light a dispersive glass, the light no longer falls to the floor, but is spread out in a broad, divergent beam, falling with nearly equal intensity on walls, ceiling, and floor. We must bear in mind that we gain nothing in the total amount of light entering the room, but we have simply redistributed the light, taking up from the floor that which fell there and was comparatively useless, and sending it in directions where it is of more service. The result of the examination of the various glasses was to show that a finely ribbed or corrugated glass was better than the others, as it gives the widest and most uniform distribution. There is no apparent gain in corrugating both sides. Ground glass is barred out, because of its actual loss of transparency, caused by slight amounts of moisture or dust. The ribbed glass, three-sixteenths of an inch thick, with twenty-one ribs to the inch, known now as 'factory ribbed glass,' is the best dispersive glass upon the market. When a glass of slightly better appearance is desired, that which is known to the trade as 'maze' glass is the best. It is similar to the fine ribbed glass, except that the ribs are not straight, but are bent into irregular figures."

Photometric measurements were made by taking two rooms, one above the other, alike in exposure, shape, and size, and comparing the intensity of light falling on similar portions of the two when one was glazed with plain glass and the other with the glass under examination. Broadly speaking, it was found that the centre of the room was as bright when lighted by a window of one square foot of ribbed glass as with a window of three square feet of plain glass. This was true in all lights, from a bright sunshine to a heavy thunderstorm, and with the windows facing in any direction.

The ribbed glass, says Mr. Norton, is especially useful in the factory where the question of the position of machinery, &c., is usually decided by convenience in setting it up, and the possibility of getting the greatest number of operatives into the smallest possible space. If the man near the window needs a shade, he cuts off light from the entire room; but the substitution of ribbed for plain glass does away with the necessity for the shade, and benefits, instead of harming, those remote from the window.

#### GEOLOGY IN RELATION TO ART.

At the closing meeting for the season of the Perthshire Society of Natural Science, Mr. Henry Coates (President) in his address took the above as his subject. After referring to the Art Loan Collection, the Photographic Exhibition, and the Water-colour Collection from South Kensington, exhibited at the new Sandeman Public Library, he said, if they left out of account the figure subjects at these three exhibitions, and considered only the landscapes, some interesting reflections suggested themselves when they compared the work of the brush and the work of the camera with a critical eye to details of scientific accuracy. He was not concerned for the present with the question as to which produces the more pleasing or the more artistic picture, but merely which was the more true to nature. At first sight it might seem obvious that the work of the camera must be the more accurate, being an exact transcript of nature as regarded form at least; but this was not necessarily so. In the first place, the camera was apt to give a wrong impression of proportion, especially of distant objects, because the angle which, say, a mountain at ten miles' distance, subtends in the camera was so very, very small as compared with that of a man at ten yards that the former became altogether dwarfed as compared with the latter. Then, again, the camera, although it did not make actual inaccuracies in form, very often failed to give due emphasis to important structural details in the landscape, either from defects of focus or from insufficient distinction of tone. For instance, in various parts of the Tay Valley there were very well-preserved remnants of the ancient river terraces, ranging up to over one hundred feet above the present level of the river. These terraces to any one who knew where to look for them were very clearly marked, and could be traced at intervals along the sides of the valley for miles, but the moment the geologist attempted to point his camera at them they seemed to shrink almost out of sight. The result was not due to the exaggerated imagination of the geologist, but to the inability of the camera to give a due sense of elevation and to distinguish between the various delicate tints of green and russet which made up the colouring of the hillside. Both of these mechanical errors could, of course, be easily rectified by an intelligent painter who knew enough of geology to correctly interpret the phenomena before him. The position, therefore, which he wished to prove was that the artist had it in his power to interpret nature even more faithfully than the photographer, but that very frequently he failed to do so for lack of a little elementary knowledge of natural science.

If they examined an historical collection of paintings arranged chronologically, they should see that the lack of scientific knowledge to which he had referred applied very much more to the earlier than to the recent schools. Indeed, the progress evinced was, to a large extent,

contemporaneous with the progress of the science of geology itself; and one might go even further, and point out that interest in the study of a landscape as a thing of beauty in itself was a growth of comparatively recent times. Of course, there were very notable exceptions, but as a rule the early painters regarded landscape as merely an unimportant adjunct. This was changed now, but there was still a lingering feeling amongst many artists that attention to minor details of earth structure was something beneath their notice, or, at least, that too much attention to such details would destroy the artistic value of their work.

Now, he was not in any way arguing against the views of the "impressionist" school of recent years, that was to say, he did not imply that features of the distant landscape should be reproduced with telescopic distinctness. By all means let them be veiled by all the atmospheric softening that nature herself loved to draw over landscape, and even let that be exaggerated in harmony with the most myopic visions; but what he did insist on was, that whatever details were portrayed, or even faintly indicated, should be true to nature, and should not give even an impression of something which was utterly impossible. He did not profess to be an art critic, and therefore it would be presumptuous on his part to single out any particular artist for adverse criticism. He might, however, from a purely geological point of view, be allowed to point out some of the errors into which artists frequently fell for lack of a little knowledge of earth lore.

In the latter part of his paper Mr. Coates pointed out the principal errors into which artists without a knowledge of geology were apt to fall, and mentioned notable exceptions, such as the late Sir John Millais, John McWhirter, and the late Sam Bough. If even a Reynolds required to mix his colours "with brains" surely it was not too much to insist that the brains of those who aspired to be landscape painters should be instructed in the principles of landscape geology. Indeed, he would go further, and insist that courses of instruction in geology should be established in connexion with all great schools of art, from the Royal Academy downwards. In all these human anatomy was made an essential element in the instruction, and rightly so; but, if it was necessary to have an acquaintance with the skeleton or framework of the human body, and with the muscles which clothed that framework before they could correctly delineate the outward features of the "human form divine," surely it was necessary to have some knowledge of the rocky framework of our earth and of the superficial deposits which cover that framework before attempting to transcribe the features of the landscape. He believed he was safe in saying that scientific accuracy was more frequently to be met with in the Scottish school of painters than in any other. The reason for that probably was, that modern geology took its rise largely in Scotland, fostered partly by the philosophical and inquiring tendency of the Scottish mind, and partly by the wonderful complexity and interest of Scottish rocks. The poet, if his word-painting were to be true to nature, should know something of the past history of the globe, and how its present features had their origin. Much had been written on the question as to whether a scientific knowledge of nature tended to diminish their appreciation of her beauties. For his own part, he could only say that the more he knew, even in a very imperfect degree, the more he wondered and admired. He would even go a step further, and say that, the more he knew, the more he revered the Author of all. It had always seemed to him that those who affected to despise the study of natural science on the ground that it tended to disillusionise the imagination were just those who had not the inclination or the ability to apply themselves to such study. In conclusion, he would sum up his argument by stating that the artist, whether he be poet or painter, who could produce an artistic transcription of nature must produce one that is free from inaccuracies of detail; and to be able to do that he must be possessed of a certain definite amount of scientific knowledge.

#### THE GREAT TELESCOPE AT THE PARIS EXPOSITION OF 1900.

The great telescope which is to figure at the Exposition of 1900, and which is due to the initiative of M. François Deloncle and the skill of M. P. Gautier, will surpass the most powerful instrument of the kind that has ever been constructed. The greatest telescope that exists at present is that of the Yerkes Observatory, says *La Nature*, the objective of which is 3'28 feet in diameter, and the focal distance about 65 feet. It moves around an axis fixed in the centre, and in a vast cupola 78 feet in diameter.

The telescope of 1900 has an objective 4'1 feet in diameter, and a focal distance of 65 feet, and its weight exceeds 44,000 pounds. It was therefore out of the question to think of placing the instrument under a cupola 209 feet in diameter, as this would have required foundations of exceptional solidity, the manoeuvring would have been difficult, the flexions and distortions of the glasses and tubes would have been considerable, and the net cost would have been extremely high.

M. Gautier decided upon a very advantageous form, and one that, under the circumstances, was necessary—that of the Foucault siderostat (a heliostat regulated to sidereal time).

This instrument consists essentially of a movable plane mirror, actuated by a clockwork that causes it to move in such a way that the

luminous rays thrown upon it by a star are, after their reflection, sent in a fixed and absolutely invariable direction. If the axis of the telescope be placed in such direction, the observer, upon putting his eye to the eyepiece, will see the image constantly during the entire time in which the star remains above the horizon, and will be able to study it at his leisure, and to make drawings and photographs of it.

The siderostat comprises a circular mirror 2 metres ( $6\frac{1}{2}$  feet) in diameter, absolutely plane and giving excellent images, and of a 196 feet telescope placed horizontally in a line running north and south. The telescope forms the images to its focus, where they may be examined by means of an eyepiece, or be received upon a sensitised plate, or be projected upon a screen placed in a hall in which they will be exposed to the view of numerous spectators.

Let us now pass to the details. The mirror consists of a glass cylinder,  $6\frac{1}{2}$  feet in diameter and  $10\frac{1}{2}$  inches in thickness, and weighs 7920 pounds. It is arranged in a 6820 pound tube, and is kept in equilibrium through a system of levers and counterpoises.

All this part is fixed in a mounting of which the total weight is 33,000 pounds. The base of this mounting floats on mercury contained in a tank, and the thrust of which eases it of  $\frac{1}{10}$  its weight. Hence the clockwork that directs the apparatus has merely to displace a mass of 33,000 pounds, and its motive weight is but 220 pounds.

The siderostat comprises (1) a cast-iron base 34 feet in height, of which the southern part supports the horary axes, parallel with the line of the poles, and its toothed rings; (2) the declination circle; (3) the clockwork movement, connected with the circle and its weight; (4) the cranks which serve respectively for the tangent screw, for the displacements of the horary circle, for the declination circle, and for the winding up of the clockwork. The part situated at the south comprises: (1) the support of the mirror, mounted in the tube and resting upon the breech, with the screw that permits of displacing it; (2) the axis of direction of the mirror, which slides in a tube, fixed upon the diameter of the declination circle; (3) the counterpoise of the mirror; (4) the mercury reservoir; (5) the windlass, designed to raise the receptacle for the silvering mirror; (6) the rollers of the support; and, finally (7), the regulating screws of the siderostat. The objectives are 4.1 feet in diameter, one of which is designed for visual observations, and the other for photographic work. They are mounted together upon the same carriage, the base of which rolls upon the rails by means of wheels, in such a manner that one or the other can be easily adapted to the extremity of the telescope, which is in the vicinity of the siderostat. The tubes that carry the crown and flint-glass lenses are mounted upon the rails. The flint and crown glasses may be separated from each other in order to permit of wiping off any dust that may settle upon them.

#### BOYER'S IMPROVEMENTS IN FLASHLIGHT.

M. BOYER thus describes his invention:—

"I provide an upper plate or disc, A, made of wood, ebony, or the like non-conducting material adapted to be rotated by clockwork on a lower plate or disc, B, made of a like material. On the lower plate, B, which is provided with insulating supports,  $b^1$ , the clockwork mechanism, C, is mounted, which is wound up by a key,  $c^1$ , on the under side of the plate. To the revolving part,  $c^2$ , of the clockwork, C, on the plate, B, vertical screw threaded rods,  $c^3$ , are secured which can fit into corresponding

holes,  $a^1$ , formed in the upper plate, A, so that the said upper plate may be passed down over the rods,  $c^3$ , and firmly clamped to the aforesaid revolving part,  $c^2$ , by screw nuts,  $c^4$ , so that the two plates are in the relative positions indicated in fig. 1, and both can then be rotated together, the lower plate, B, itself remaining stationary. The lower plate is formed with a projecting side piece,  $b^2$ , on which are mounted on the under-side coils, D, connected to a source of electricity by conductors,  $x, y$ .  $d^1$  is a pawl or catch forming a part of the armature,  $d^2$ , and  $d^3$  is a spring tending to keep the armature from the coils when there is no current passing through them. On the under side of the plate, A, I provide an inner and outer set or series of abutments or stops,  $a^2$  and  $a^3$  respectively, so that the pawl or catch,  $d^1$ , will come against one of the

series of stops,  $a^2$ , when the armature is attracted by the coils, D, and against one of the other series of stops,  $a^3$ , when repelled from the coils by the spring,  $d^3$ . On the top side of the plate, A, the cups or receivers, E, formed with porcelain or the like lining,  $e$ , containing the magnesium or the like material for obtaining the flash-light, are arranged preferably in concentric circles as shown in the drawings, and held in place by spring catches,  $e^1$ , and clips,  $e^2$ , which may pass through holes formed near the base of the said cups, as shown in fig. 1. Any suitable means may be

employed for igniting the magnesium or the like contained in the cups, but I prefer to employ one of the following arrangements in combination with the upper plate rotated on the lower plate as already described. In the arrangement shown in the drawings I provide spring contacts,  $b^3, b^4$  (fig. 2) on the upper side of the lower plate, B, connected to a source of electricity by conductors,  $x^1, y^1$ , which are caused to complete a circuit by coming into contact in turn with the aforesaid catches and clips,  $e^1, e^2$ , which are passed through to the under side of the plate, A, for this purpose, and each cup or receiver, A, may be provided at its base with coils, so that, on the passage of the electric current, a sparking takes place between these coils in the cup situated over the spring contacts,  $b^3, b^4$ , which ignites the magnesium or the like contained therein; or, in place of the coils, I may use a thin copper wire or other material capable of being rendered incandescent, which is passed through the holes at the bases of the cups so as to come into contact with the spring catches and clips.

"In place of using electrical means for igniting the magnesium or the like in my apparatus, I may employ in the cups or receivers a fulminating cap or explosive or the like, which may be ignited by percussion,

for example, by a spring hammer arranged on the fixed part of the apparatus, operated by a cam or projection on the revolving part, or I may cause the ignition by friction by causing a strip of phosphorus or the

like in contact with the magnesium to be drawn over a rough surface, or the magnesium or the like may be ignited by causing water to drop on any material or compound which can be exploded or ignited by this means.

When the apparatus is to be used, the clockwork is wound up and a current of electricity is passed through the coils so as to withdraw the pawl from the stop of one set, which keeps the plate with the cups from rotating; the upper plate, being released, commences to rotate until a stop on the other set comes against the pawl in its new position. When this movement takes place, the magnesium in the cup, which is now brought over the spring contacts, is ignited, for example, by a current of electricity passing from the conductors,  $x^1$ ,  $y^1$ , to the spring contacts and clips, and the coils or wire at the bottom of the cup which are in electrical contact with the same. Or the ignition may be effected by the mechanical means described or any other suitable means which will cause the ignition of the magnesium in a cup for every partial revolution of the plate. When the electric current is cut off from the magnet, the pawl returns to its original position under the influence of the spring, and the upper plate being released again commences to revolve until the next adjacent stop on the first set or series comes in contact with the pawl. Flash-lights can thus be readily obtained in quick succession by the rotation of the upper plate or disc, which can be operated from any desired distance."

### THE OPTICAL LANTERN.

By ANDREW PRINGLE, F.R.M.S. 149 pp. Price 2s. 6d.  
London: Hampton & Co., 13, Cursitor-street, E.C.

It is eight years since the second edition of Mr. Pringle's admirable book was published, so that the third edition, which has just been issued, may be looked upon as new in that it appeals to a fresh and greatly enlarged circle of readers. The lines upon which it is cast are indicated in one of the prefatory notes, which advises the reader that negative and lantern-slide making are denied reference, and that the author addresses himself less to the popular lecturer than to the photographer and the teacher. Mr. Pringle, it is superfluous to say, is an old and practised hand in lantern work, and in the twenty-one chapters of his book he takes the reader over practically the whole field of "straight through" projection with the certainty and sureness that only long experience can give. Chapters on acetylene, the electric light, and animated photography show that the author well redeems his promise of bringing his book up to date, and in the appendix the very latest forms of lantern apparatus are described.

The *Optical Lantern* is well printed and freely illustrated. The information it gives is so sound and authoritative, that Mr. Pringle's book, which has had the advantage of the revisional assistance of Mr. W. B. Bolton, can be safely recommended as one of the standard books of the photographer's library. In addition to those above mentioned, the chapters on The Condenser, The Projecting Lens, Illuminants, and the Practical Working of the Lantern, are of especial value.

### THE LIGHTING OF THE MAGIC LANTERN.

Among the evening lectures organized in Paris by the societies of popular instruction, those on history and geography were not well attended until we illustrated them by appropriate projections.

The petroleum lantern was first employed, but had to be discarded on account of insufficient lighting and its fuliginous flame. The electric, oxyhydric, and oxyetheric lights are, no doubt, quite effective, but they are expensive, and, besides, cannot be procured everywhere. For these reasons we decided to use the brilliant lighting of acetylene, this gas not being more dangerous to handle in small volume than coal gas, and, at equal delivery, giving a light fifteen times more luminous.

The apparatus, made on our suggestion by Cercked and Deans, is entirely safe and can be easily placed into the magic lantern.

We have stated that this apparatus works well and the light is quite steady during an hour. As to the intensity of the light, a burner of the Manchester type delivering sixty litres per hour gives eighty candles, that is about twice the intensity of a four or five-wick petroleum lamp.

The apparatus generating the acetylene (called *Luciphore*) is constituted by an ensemble of three tubes set one to another; the exterior tube has a diameter of 0<sup>m</sup>.06 and is 0<sup>m</sup>.30 high; the interior tube, or case, can be taken apart in several pieces to facilitate cleaning; it contains a capillary tube, with a groove and an interior wick, fitting the interior part of the case into which one places the carbide. This case is set in the second, which is provided with a cock for the outlet of the gas.

The whole is placed in the interior tube where one pours the water necessary for the decomposition of the carbide.

The loading and cleaning do not require more than two minutes; the quantity of carbide is 300 grammes.

To obtain the acetylene necessary for a lecture of one and a half hours, that is, the ninety litres which can be evolved from the above quantity of carbide of calcium, it suffices to pour a glass of water in the envelope

and instantly one is ready for lighting the lantern, the carbide having, of course, been placed in the interior of the case beforehand.

When the lecture is over, one pours off the water not utilised, and hangs up the apparatus to the exterior of a window for a few minutes, in order not to be incommoded by the disagreeable odour of the gas evolved.

We shall not speak of the economical question; for a lighting of one and a half hours the 300 grammes of carbide suffice. They cost twenty centimes (4 cents) and give an intensity of light nearly treble that from petroleum.

One knows that for the "ideal" lighting of the magic lantern, the source of light should be limited to a mathematical point; it is for this reason that the best lighting is the electric arc. Acetylene gives a brilliant flame of a very small diameter.

By increasing the delivery by adapting a large burner to the apparatus, one can obtain an intensity of more than 200 candles, but, consequently, the duration of the lighting is less. In this case the apparatus should be placed in a pail of cold water to absorb the heat evolved by the rapid formation of the gas, which, however, would have for only inconvenience to produce the evaporation of the water in the apparatus, and, consequently, a crepitation of the flame by the steam carried with the acetylene.

CHARLES GRAYIER in *The Photographic Times*.

CROYDON MICROSCOPICAL AND NATURAL HISTORY CLUB (PHOTOGRAPHIC SECTION).—On Friday evening last, to a numerous audience, Mr. P. Crowley, a member of the Club, gave a most interesting and detailed description of the Riviera, no less than twenty towns being referred to, among them being Cannes, Grasse, Nice, Monte Carlo and its noted casino, Monaco, Mentone, Cap Martin, Cimiez, and Gorbio. Some of the principal buildings were described: the curious narrow streets, with the arches across to strengthen them in case of earthquake shocks; the manners and customs of the people; the markets; some of the lovely gardens which are to be found in that charming locality; and of the flora, especially the palms, aloes, and prickly pear, were each and all brought vividly before the audience. The verbal description was supplemented by means of 100 photographs, shown as lantern slides, taken and produced by Mr. Crowley himself. At the conclusion, a hearty vote of thanks, proposed by Mr. W. M. Holmes, who occupied the chair, was accorded to Mr. Crowley.

THE MOTHER-OF-PEARL INDUSTRY.—According to Mr. R. Lydekker, F.R.S., in the current number of *Knowledge*, the mother-of-pearl industry occupies a by no means inconsiderable place among the many and diversified enterprises which afford safety-valves for the more energetic of our countrymen. Most of us cultivate the acquaintance of this beautiful commercial product through the medium of studs, buttons, links, and so on—those little, though indispensable, things which on occasion are so liable to rouse feelings that find relief usually by an explosion in the form of bad language. Trifling as is the quantity of mother-of-pearl which finds its way into any single home, taken in the aggregate the full amount and value of the imports are represented by hundreds of tons and thousands of pounds. "About 1853, from which date till 1870 annual returns were issued by the Board of Trade, the mother-of-pearl imports seem to have received a new impetus, the following being the seven maximum years during that period:—

1856	= 43,032 hundredweights, valued at £76,544
1859	= 40,003 " " 67,859
1869	= 37,662 " " 94,015
1854	= 36,644 " " 88,305
1867	= 36,175 " " 70,426
1857	= 34,324 " " 57,819
1868	= 32,002 " " 64,869

From this it appears that, in the last year mentioned, the average price was almost exactly £2 per hundredweight, while in 1869 it was somewhat above, and in 1856 rather below that sum." We are all more or less familiar with the characteristic iridescent play of colours exhibited by mother-of-pearl, and it is interesting to learn that "unlike the colouring of the outer surfaces of shells, which are due to the deposition of pigment in their substance, the iridescence of mother-of-pearl is caused by the mechanical arrangement of the particles of the shell itself, which form a number of extremely minute and delicate ridges and grooves, thus breaking up the light falling upon them into its constituent elements. Pearly lustre is, indeed, precisely analogous to the colours of thin plates or films, and that it is really due solely to mechanical structure is evident by the fact, that impressions taken from mother-of-pearl in gum or fusible metal exhibit the same play of colours."

THERE is a remarkable collection of astronomical photographs at Harvard University. They are kept by Mrs. M. P. Fleming, who is curator. The photographs taken at Cambridge and Arequipa are preserved and arranged in catalogues, as is done with books, but the plates themselves are actually preserved, because no paper copy can repeat all the minute accuracy of the original negative on glass, and prints are not taken from them for scientific use, but only for illustration. If one is destroyed, it cannot be replaced; so it necessitates the greatest possible care in preserving them.

### LANTERN MEMS.

THE scientific event of the year, the Royal Society's *Soirée*, is invariably productive of some special announcement, or the means of introducing to the public some important invention in connexion with science, and, although the one held on May 3 can scarcely be considered a red-letter one in this respect, there were sufficient high-class exhibits to demonstrate the fact that our professors are not by any means asleep. One missed some of the well-known names in the catalogue of exhibits, but it is only reasonable to expect absentees now and then, for the work entailed in preparing suitable demonstrations for the occasion is considerable and the inventive faculty cannot always be at command; or, if new ideas do occur, they cannot take practical shape just at the time to suit this social function.

THOSE who have not personally exhibited at scientific meetings hardly realise the amount of time consumed by the demonstrator in preparing beforehand, and the energy expended at the time, with the object of interesting the audience, and hence a cool reception is detrimental to future efforts in this way. Men who are busy professionally hesitate to devote the necessary time and undertake the fag of a long evening's explanation, unless some sort of kudos is likely to come out of the attendance. My opinion, from close observation, is that those who do not work for the benefit of science or with a desire to entertain others are apt to be somewhat hypercritical and look for something of such a high standard that only a minority of ordinary workers can hope to reach. A little more graciousness, if not encouragement, would bring on new men who have gone a little out of the beaten track, and their knowledge and experience would, if imparted to a society, be of general service.

REGARDING the exhibits at the *Conversazione*, one of the finest apparatus I have ever seen for the projection of photographic work was a photo-micrographic apparatus designed for the Jenner Institute of Preventive Medicine by Mr. J. E. Barnard, F.R.M.S., and Mr. T. A. B. Carver, B.Sc. It was beautifully made, and so well constructed that perfect rigidity was secured; the stand being constructed on a stiff girder, vibration was apparently entirely neutralised. The source of light was the electric arc, and very clever arrangements were provided for perfect centering and focussing. Scales were arranged on the bed of the instrument, so that, a suc-

cessful result once obtained and the details registered, similar results could be obtained at any future time, as the extension of bellows, position of dark slide, lens, &c., could be exactly located. The illumination of opaque objects was also cleverly provided for.

\* \* \* \* \*

THE Nernst electric light incandescent lamp, which was originally shown at the Society of Arts some few months ago, and stated by Mr. James Swinburne as likely to revolutionise electric lighting, has been considerably improved since, and now, instead of requiring a light to warm the rod of rare earth before the electric current would pass through it and make it incandescent, it is warmed by the heat radiated from a coil of fine platina wire, in which the rod, or electrolytic, conductor is enclosed. As soon as the current is switched on, the wire begins to glow, and, when the rod is warm enough to act as a conductor, the current is cut off automatically from the coil, and the rod becomes incandescent and emits a beautiful light. The size of the lamp, as now constructed, is about the same as that of a sixteen-candle-power incandescent electric lamp of Edison-Swan pattern. These rods of rare earth are comparatively strong, and after a fairly long life can easily be replaced. Moreover a vacuum is not required as in the case of the carbon filament.

A MAGNIFICENT piece of work was shown in the Michelson Échelon Grating Spectroscope, which gave splendid dispersion. The accuracy of the plates—fifteen in number—forming the steps was such that they held together (between two clamps) by surface contact only, and the edges of each plate "en échelon" formed the medium for dispersion. The greatest error permissible between each was  $\frac{1}{100000}$  inch, each step being 1 millimetre wider than the previous. The resolving power equals 118,000.

\* \* \* \* \*

SOME fine natural colour photographs of zoological and botanical subjects were shown, mostly from life, taken and prepared by the exhibitor, Mr. W. Saville-Kent, F.L.S. They were three-colour work, each transparency being tinted with the colour complementary to that of the respective negative and the films superimposed in correct register. The brilliant tints and faithful reproduction of colours should make these slides valuable as records of biological subjects. Mr. Kearton had exhibited on the screen some of his interesting and beautiful photographs of wild birds in their native haunts, also of descents of precipices to photograph eagles' nests.

\* \* \* \* \*

THIS reminds me of another intrepid worker in this field of natural history, Lieut.-Colonel Willoughby Verner, who recently showed me some most interesting photographs of eagles' and vultures' nests taken with a daylight changing film camera; one of a young vulture in its nest, and another with the naturalist actually standing in the nest on the top of a very high tree holding an egg in his hand. The adventures that have befallen this gentleman in his

various sporting expeditions are most exciting, and will, no doubt, in due time form the subject of a book that will be eagerly read by all lovers of adventures and those who desire information of the habits of birds gradually becoming extinct. Without doubt, it is this wonderful spirit of pluck and daring, as so often exemplified in the British officer, that makes the odds in his favour when a trial of strength and skill takes place, or when he has pitted against him excessive numbers in war time, and ensures success. Photography is still likely to remain popular while so much good work can be done by simple apparatus.

I CANNOT close these "Mems." without reference to a capital arrangement for showing the waves produced by different conditions of burning of the electric arc lamp. These oscillographs, as shown by Mr. W. Duddell, gave the potential difference and the current waves, and are therefore particularly useful in investigations with alternate currents. An apparatus was also shown which, by miniature projection on a ground glass screen attached to the instrument, traced the wave forms in the same way as that projected on the ordinary lantern screen, and should be most useful to professors, electric-light engineers, &c. It is essentially a galvanometer that has the extremely short periodic time of one ten-thousandth of a second, and is perfectly dead beat for an arranged sensibility. It was very interesting at Burlington House to see the way in which this was adjusted to agree with the alternations of the current, and which was done by the rhythm of the alternations.

G. R. BAKER.

#### NOTE ON SOME PROPERTIES OF THE RADIATIONS OF URANIUM AND RADIO-ACTIVE SUBSTANCES.\*

SINCE the last note upon the radiations of uranium, which I presented to the Academy in the month of April, 1897, some important investigations have been published concerning this question. I need only recall those of Lord Kelvin, Messrs. Beattie and Smoluchowsky, and Mr. Rutherford, respecting uranium, and M. Schmidt, who has found in thorium properties analogous to those of uranium; and, lastly, the splendid researches of M. and Mde. Curie, which have resulted in the discovery of two new substances, polonium and radium, both considerably more active than uranium. I propose to summarise the conclusions which may be deduced from the study of several hundred photographic negatives made during the past three years, and they show how complex this phenomenon of radiation is.

Amongst the properties to which I drew attention at the beginning of my researches, as characteristic of this hitherto unknown radiation, there were three of fundamental importance, which have been observed by every student since. These are the spontaneity of the radiation, its permanence, and its property of rendering gases conductors of electricity.

The intensity of the radiation of uranium does not appear to suffer any notable change in the course of time. The various compounds which I enclosed in a double box of lead on May 3, 1896, and which have been protected since then from all known radiations, continue to impress an image upon a photographic plate with about the same intensity as at first. There appears to have been a slight diminution of energy during the first months; but, since then, the intensity seems to have remained stationary. The difficulty of experimenting with photographic plates of uniform sensitiveness and developing them under identical conditions make it impossible to speak with more precision.

Amongst the other properties mentioned by me, polarisation, reflection, and refraction have not been confirmed by the various students who have repeated the experiments. Neither have the observations which I have made during the last three years confirmed my first conclusions, and they have shown that the phenomena are more complex.

Thanks to the courtesy of M. and Mde. Curie I have been enabled during the last few months to repeat with polonium and radium experiments identical with those I had made with uranium.

*Polarisation.*—No successful experiments could be made showing that the radiation from these substances could be polarised. An early photographic print, shown at the Academy in March 1896, exhibited difference of absorption with plates of tourmaline, according to their crossed or parallel position. A second print obtained a few weeks later gave similar results, but all subsequent experiments with uranium, as well as radium,

have been negative. This result agrees with those of other observers, and the only conclusion which can be drawn is, that the various tourmalines which have been studied are not dichroic for these rays, although they may be capable of assimilation for luminous rays. I have not, however, been able to detect the cause of my first two prints differing from those subsequently obtained.

*Reflection.*—The experiments by which I tried to determine if the radiation of uranium and the other substances could be reflected led to very interesting results. In my preceding notes I described certain experiments the results of which seemed to harmonise with the hypothesis of normal reflection. For instance, when fragments of the active substance were placed on a slip of glass under a bell-shaped tube and then placed upon a photographic plate, not only did a silhouette of the substance appear upon the plate, but also the contour of the tube and the whole of the enclosed surface, although less markedly than the silhouette of the substance. This experiment, after frequent repetition, was varied two years ago in the following manner: A glass tube forming an inverted U, about two centimetres high, closed with slips of glass, was stood upon a photographic plate; within one side of the tube a piece of metallic uranium was placed; a screen of lead was inserted between both branches of the tube to prevent the radiation of the uranium affecting the opposite branch, which was empty. After several days' exposure an impression was observed corresponding to the form of the interior surface of the second branch of the tube, as though the radiation had been reflected by the upper part of this bent shade. A similar experiment was made by substituting for the bent shade a steel mirror placed horizontally, and a somewhat vigorous impression of the radiation from the mirror was obtained.

But these experiments (and several others, which I will not describe here) do not permit us to conclude that normal reflection occurs. I have repeated one of my first experiments many times with variations. This consists in suspending above a fragment of active material a small concave tin mirror, giving good optical images and adjusted in such a manner that the image of the fragment of material is projected upon the plate. I have not obtained any impressions by these means, but in most cases the surface of the mirror seemed to be the source of a new radiation, giving a stronger image for the margin of the mirror than for the central portion, situate at greater distance from the plate.

This experiment seems to favour the hypothesis of an emission of secondary rays analogous to those which M. Sagnac has discovered in relation to bodies upon which X rays impinge, or the hypothesis of diffuse reflection. M. Schmidt's experiments with thorium have also induced him to admit a phenomenon of diffuse reflection.

I then arranged fresh experiments to examine this irregular reflection or new emission, using as active substance carbonate of radium; but, as this substance is luminous by phosphorescence, it is necessary to envelop the plate with black paper to avoid the very energetic action of the luminous radiations. A small cylinder of paper containing radium was placed a few millimetres above a photographic plate thus protected. Strips of various substances—metals, such as copper, lead, tin, zinc, bismuth, aluminium; paper, glass, paraffin, &c.—were placed at various inclinations upon the plate, from which they were separated by a very thin sheet of mica to prevent the disturbing effect of the metallic exhalations. When the plate was developed, after several hours' exposure, opposite the shadow cast by each substance, very energetic action was found at the front margin, which evidently emanated from the objects. This action did not differ much for the various substances. Metals, whether polished or rough, seemed about equal in their effect, but fluorine was particularly energetic in its action.

Moreover, in all the experiments which I had previously conducted, whenever the radiation fell directly upon the body, such as glass, for instance, the parts affected, when very near the plate, were the seat of a radiation much more intense than the incident radiation. This radiation did not extend very far from the object, say 1 mm. from the points of impact, and when the experiments were made in rarified air, under a pressure of 2 c. of mercury, there was no marked extension. The intensity of effect leads one to believe that this is a secondary radiation; but, as this radiation appears to be rapidly absorbed by air, whilst, in the experiments mentioned above, effects of diffuse reflection were observed with uranium through several centimetres of air, it is possible that we have the presence of different radiations in the two cases, or even two distinct phenomena: an emission of secondary rays and diffuse reflection.

*Refraction.*—The study of refraction also led to contradictory results. I have constantly observed the following in the prints I have obtained by means of uranium during the past three years, and the same is also the case with thorium and radium.

\* Translated from the *Moniteur de la Photographie*.

When the active substance was placed upon a strip of glass, either directly or enclosed in a glass or paper tube, and the strip was placed immediately upon the photographic plate, or with an intervening sheet of black paper or thin plate of aluminium, or when the strip of glass was kept at a short distance from the plate without touching it—in all these cases, upon development of the impression, it was observed that the silhouette of the strip of glass was bordered with a white band resembling the shadow the vertical sides of the strip would cast, and the parts where the shadows crossed were whiter than the rest. Outside this band the photographic impression was sometimes very marked. The band varied in breadth with the thickness of the glass, or the inclination of the radiation, or the distance of separation from the photographic plate, and it was then much more diffuse. All these characteristics bear resemblance to a cast shadow, and can be reproduced by light if a substance luminous by phosphorescence is placed upon the strip of glass. The luminous radiations of sulphide of calcium or carbonate of radium may be taken, and it can be shown that the light is refracted by the sides of the strip, and totally reflected upon the vertical surfaces. It would be natural to suppose that the results obtained through black paper or aluminium are due to analogous phenomena of refraction and reflection. All substances transparent to the radiations of radio-active bodies presented the same phenomena when in strips with vertical sides, as, for instance, mica, sulphur, paraffin, copper, aluminium, and the edge of a sheet of black paper or card.

The explanation just given could not be accepted unless it were verified by experiments to ascertain if the radiation under consideration could be bent by a prism of transparent material. Now, experiment has shown that the radiation passes without appreciable deviation through prisms of glass or aluminium.

The following arrangements enabled me to ascertain this fact:—

Two small rectangular isosceles prisms of crown glass 4 mm. high were fixed by their hypotenuses to a strip of glass so as to form a channel. They were placed upon the photographic plate, resting upon the edges of their dihedral, with their hypotenuse surfaces upwards and horizontal. Above their common angle, and about 10 mm. from the glass plate, a small tube about 1 mm. in diameter filled with carbonate of radium was placed parallel to the angle. Under these conditions it may be easily ascertained that the light emitted by the phosphorescence of the carbonate of radium does not pass between the two prisms and is refracted through their outer surfaces, the angle of which is 35°. If the luminous radiation is cut off by a sheet of black paper or aluminium, the result is quite different and the photographic impression shows that the active radiation passes undeviated, with progressive absorption corresponding to the progressive thickness of material of which the prisms are formed.

We also made the following experiment: An oblique slit was cut through a sheet of lead 3 to 4 mm. thick, in such a manner that the radiation from a very thin tube of radiant matter placed parallel could pass through it. The slit was partly covered on the other side with prisms of various substances, a prism of glass 45°, prisms of aluminium and copper of about 35°. The radiation after traversing the slit and the prisms was received upon a photographic plate, and the image of the straight line did not show any appreciable deviation where the glass and aluminium had been interposed. This experiment is analogous to one made by Mr. Rutherford, which also gave a negative result. These latter experiments appear to be conclusive, and an explanation of the facts I first mentioned remains to be found.

*Absorption.*—In the course of the various experiments which I have mentioned, it will be noticed that the radiations emanating from various radiant substances are not only unequal in their intensity, but also differ in absorbability by the various substances through which they may have to pass. Uranium and radium emit radiations which, approximately, pass through the same substances, but the latter is considerably more active than the former. The radiations of polonium, on the contrary, are distinguished by their remarkable absorption. They are badly transmitted by paper, which readily transmits the radiations of radium. An extremely thin plate of mica reduces them considerably, whilst the same plate has much less effect upon the radiation of radium. The latter traverses plates of quartz and spar, whilst the rays from polonium will not penetrate them. Polonium is much more active than uranium behind a leaf of beaten aluminium. Uranium is distinctly more active than polonium behind a plate of aluminium 2 mm. thick. These examples might be multiplied, and they extend also to thorium.

In this order of phenomena difference of absorption appears at present

to be the only indication by which radiations of different nature may be characterised.

To resume. The radiations of radio-active bodies exhibit characteristics which bear nearer resemblance to X rays than to ordinary light. The presence of effects analogous to secondary rays accentuates this resemblance.

Among the inexplicable facts which are met with in the study of this subject one of the most singular is the spontaneous emission of a radiation without a known cause. If it could be demonstrated that this radiation does not correspond to an exertion of energy, the condition under which uranium exists might be compared with that of a magnet, which has been brought into that condition by previous exercise of energy, thenceforward retaining it indefinitely, and maintaining a vicinal field where transformations of energy may be produced. The condition of uranium might also be compared with that of bodies phosphorescent by heat, which seem to retain indefinitely the luminous energy which they have acquired. But the reduction of photographic substances, and the excitation of the phosphorescence of the platino-cyanides observed by M. and Mde. Curie in the case of polonium and radium are phenomena which imply a loss of energy, of which we cannot see the source excepting in the radio-active substance. As this loss of energy is very slight, it would not be inconsistent with what we know concerning phosphorescence to suppose that these substances have a relatively large reserve of energy which they emit by radiation in the course of years without appreciable loss. At any rate, it has been found impossible by physical means to bring about an appreciable variation in the intensity of emission.

HENRI BECQUEREL.

## A FEW ESSENTIALS TO SUCCESS IN LIMELIGHT PROJECTION.

### II.

ONE of the first essentials in limelight working is the absolute certainty of an operator being able to command a steady and silent light. In every audience there are always those who have a dread of any hissing of jets, and, what is quite as disconcerting, the well-known miniature explosions or bangs. With our modern apparatus these need never occur, and, whenever they are allowed to take place, it is quite certain an operator either does not know his business or else for the time being is acting in a careless manner.

The snapping noise, frequently heard when a novice proceeds to light a mixing jet, is caused by admitting a too sudden flow of oxygen into the already existing quantity of hydrogen that has been communicated to the mixing chamber of the jet, and, to avoid these annoying little explosions, the hydrogen gas must first be turned on to about half the quantity that will be finally required when the jet is working at its best; this is lighted at the nipple and allowed to burn for a few minutes; the oxygen is then, with the slightest possible opening of the taps, admitted *very slowly* at first. If this gas is being properly controlled, there will only be just enough oxygen passing as will cause a lowering of the yellow hydrogen flame, and then, by very carefully and slowly admitting a little more oxygen, a point will be reached at which the gases are burning in their proper proportions, and the moment the quantity of oxygen is permitted to exceed this, that moment the "bang" takes place. It is, therefore, a golden rule to follow, viz., "never to allow the oxygen being in excess of the proper proportion to the amount of hydrogen burning at the jet." If more light is required, the hydrogen must always be increased first before any additional oxygen is turned on, and, when these little rules are given attention to, there will be no "bangs" or "snaps" at the jets.

To overcome "hissing" there is no doubt that the newer form of jets, or, for that matter, an old pattern of jet, to which a modern fine adjustment tap has been fitted, provides great security in its prevention. It is not generally known that these splendid taps are easily added to any pattern of jet, such as have their taps in the old-fashioned form or in the winged shape, and, when the new fine adjustment tap is added to it, the very minutest amount of increase or decrease of pressure is easily communicated to the chamber. Hissing, when it arises from over-pressure, need never occur when the modern type of jets is employed. Roaring or hissing was far more common twenty years ago than now, but it still does turn up sometimes, and whenever it is attributable to over-pressure the cure is easily applied by suddenly turning off the oxygen by the wing tap and then gradually opening it again, and finally adjusting the pressure by the fine screw tap. In the older form of jets, in which these double taps did not exist, of course this was not nearly so easily accomplished. If the noise at the jets is caused by a bad nipple when a fair pressure is turned on, a new nipple should be inserted, and an experienced operator always has a spare one at hand. Sometimes a slight noise may be caused by the nipple clogging a little with a bad quality of coal gas, but this is not of frequent occurrence, and a long and very finely pointed needle will, when applied to the orifice of the nipple, generally remove any defect. The above are the chief elements in

obtaining a silent light. Of course, if a jet is being used of the older form in which no packing is present, for the purpose of thoroughly mixing the gases in the mixing chamber, the are not nearly so easily controlled as those in which a good supply of discs and gauze be present.

The increase of packing and in some of the more modern type of mixing jets their peculiar construction has caused makers of gas-regulators to provide for such increase of pressure as is required by reason of this increase of packing, and the newer forms of governors are now made to yield increased pressure to the jets on this account. In the early kind of gas regulators, indiarubber was, in some form or other, nearly always employed; but, by reason of its liability to give way, attention has more recently been given to a form of governor in which the indiarubber is entirely protected from injury, or, otherwise, entirely discarded in their construction. A regulator of this class was designed a few years ago by Mr. Brier of The Scotch and Irish Oxygen Company, Limited, and has acquired a large share of popularity with limelight operators, an important feature being the metallic bellows, as well as the non-liability for any of the working parts being got at. This regulator will stand a lot of knock-about wear and tear, there being no rubber used in its construction, and it can be loaded to any desired pressure, the regular pressure, however, being two and a half pounds per square inch; these have marked a distinct improvement in the utilisation of compressed gas in cylinders, when it is being used in some of the more modern forms of jets requiring a higher pressure than that usually employed in the older form.

It has long been recognised that one of the first essentials in limelight projection is that an operator be intimately acquainted with every bit of apparatus he is employing, and that no new dissolver, jet, or any other part of a limelight outfit should be relied upon without its being subjected to a thorough test. Dissolvers have many breakdowns to answer for, and it is only those having experience of double and triple lantern work that really know the importance of practically testing a new dissolver; fortunately, however, the faults in their construction are now pretty well understood, but there is a pressing need that no new article should be trusted until it has been tried in conjunction with all the other parts of the apparatus. Since the cinematograph has come into such popularity there has perhaps been less demand for double and triple deckers than formerly, and this to a certain extent has tended to popularise the single lantern in a greater degree. Still, binoculars and dissolving effects are by no means things of the past, and very probably will never lose their hold on the public; and, so long as dissolving is resorted to, so long will the same old story of difficulty with dissolvers be sure to crop up if an operator does not give personal attention to the particular dissolver he is using.

This may mean increasing the passage way of the hydrogen lead of gas, so that it is kept well ahead of the oxygen supply, and it is only by strictly attending to little details of this description that really first-class results can be relied upon. And, if it be of the first importance that an operator knows all the particulars of his apparatus, it is equally important that, when the apparatus is in excellent working condition, it should be carefully preserved. Who is there among operators who does not know from experience the hurry skurry that always ensues at the close of a limelight entertainment? This is just the most critical time of all, for, in the desire to bundle up, very probably to catch the last train, everything, so to speak, is shovelled into its place, and but little regard paid to the delicate instruments that so much depends upon. Regulators are knocked about like footballs, jets are pressed into any nook or cranny that will permit of the box closing that contains them; in fact, in nine cases out of ten, everything is packed in as hurriedly as possible. This sort of thing exists to a much greater extent than many imagine, and is liable for numerous little troubles which follow in their train.

I once knew a careful operator who was driven to his wits' end to overcome a difficulty which for a time was unaccountable. The night before all the apparatus had been working nicely, but something of the sort above described had happened so as to catch the last train. The next night, although the same apparatus was being employed, no gas could be got to flow through his oxygen-regulator. A close inspection of affairs disclosed the fact that some one had been tampering with his apparatus, and, when the regulator was finally taken to pieces and examined, a portion of metal was found imbedded in the ingress tube of the regulator which completely closed the aperture. This may have been an accident, but it looked very like a diabolical attempt to upset the show. However, an experience of this kind shows the need of always overhauling the apparatus prior to setting out for an engagement, and in cases of especial importance of being always provided with at least duplicates in the most important portions of same.

With the introduction of the modern form of jets there has also come a leaning towards the employment of larger limes, and especially is this the case in cinematographic work, the object, no doubt, being to protect the lime pin as much as possible, and with some operators the belief that a better light is secured. For a time operators seemed to be somewhat enamoured with these larger forms of limes, and they even became largely used in single lantern lecture working, but the result of two or three years' experience with them seems to be that they are not, when taking everything into consideration, any improvement over the older form and size of lime, and the writer has quite recently heard some very

decided opinions expressed by the leading operators of the day that they intend to resort to the old size and shape of hard Nottingham limes in the future. That much is due in success to a good sample of limes is only too well known, and it may surprise many readers of THE BRITISH JOURNAL OF PHOTOGRAPHY to learn that several of our best operators now only use a lime in high-pressure work for a minute or two's duration, at the expiry of which a new cylinder is placed upon the pin, the result being that during one entertainment perhaps fifty limes are used. This, of course, applies to really high-class projection, but it just goes to show what ardent lanternism really means. It shows the advantages derived by using double lanterns over those of the single form when certain kinds of entertainments have to be conducted, and this is just the one drawback to single lantern working, for we have now such admirable forms of dissolving carriers that do much to assist the use of single lanterns, the one thing wanting being a better form of apparatus for suddenly changing from one lime to another; the party that first invents this in connexion with a limelight jet will do a good thing indeed. Certainly more difficult feats have been accomplished in connexion with our jets and other parts of a lantern outfit.

Three years ago, to judge from the flattering reports that were written and circulated regarding the employment of saturators, it looked as if these had come to stay, but from the very first there was a doubt as to the advisability of employing them in lantern projections, and even those who were the most strong in advocating the use of saturators soon found, from bitter experience, that there lay a danger that was dreadful to contemplate.

I know one case where an operator used a certain form of saturator successfully for two years, but he had his eyes suddenly opened one night in Ayrshire, when he sent a flame forty feet high above the heads of his audience, and he declares to this day he has never been able to account for the accident—and this by an expert in limelight working. Saturators, however, at least, in their present or recent form would appear to be doomed; but, then, why should any element of greater danger be introduced than is actually necessary? There is now no difficulty of obtaining gas in cylinders at almost any part of the world, and the cost and extra bulk ought certainly not to outweigh that of the great security which the employment of gas confers over ether.

In single lantern working where it is confined to small discs, such as are met with in private houses and large rooms, a blow-through form of jet has always been popular, simply because the gas from the main is brought into requisition and thereby a small saving in the cost of hydrogen is effected. A blow-through jet is not comparable, however, to a well-made mixer, and the best houses are now making a practice of always working off two cylinders, even where an installation of gas is at command.

The extra lengths of rubber tubing required, also the tampering with gas fixtures as well as the extra smell always present when gas is led any distance to a lantern, go far as a set-off against the small extra cost of ten or a dozen feet of hydrogen gas, while the ease and comfort of working with a mixed jet is another important factor that has recently weighed with opticians who cater largely for private exhibitions of this kind.

It has been always recognised that in single lantern work there is no need for the employment of regulators, and no doubt this statement has been placed forward simply by reason of the almost universal employment of blow-through jets in single lantern working, but where mixed jets are used it will be found that a pair of good regulators are almost an essential to success, although fine adjustment valves may, at the same time, take their place. Over and over again I have been asked to explain how, in cases where fine adjustment valves are being used, it almost invariably happens that, after the light has been carefully adjusted and a good start made, it suddenly goes down to a considerable extent. At first the general opinion formed was that this sudden dropping of the light was attributable to want of pressure, but this hardly accounted for the great difference that takes place. In cases where half-empty cylinders are employed such a sudden falling away never happens, and a much steadier light is obtained all through; but, where, say, a full twenty feet cylinder is employed to start with, the light invariably drops suddenly. After thinking over this, I am driven to the conclusion that the sudden dropping of light is caused by the cylinder being more or less distended beyond its normal capacity, and this acts as extra pressure, which suddenly ceases when the walls of the cylinder reach their normal state. At this stage the pressure will not vary so much; it is therefore advisable to employ regulators with full cylinders, by which means a fine steady pressure is maintained.

A. T. NEWTON.

## LIFE-SIZE ENLARGEMENTS.

### II.

In a previous article reference was made to the production of suitable, but uncstly, apparatus for making of large-sized enlargements.

Any one who for the first time undertakes the making of, say, a six-foot enlargement will most likely feel somewhat anxious about the possibility of being able to focus a reasonably sharp image, as the result of such an extreme limit when working on, say, negatives of half or whole-plate sizes; for such a stretch is usually looked upon as far in excess of a fair amount of enlargement for small-sized negatives to stand, and no doubt there are many negatives that are quite useless for such being at-

tempted. On the other hand, any negative that possesses a reasonable amount of sharpness may be made to yield very good results.

In commercial work, however, where a photographer ascertains beforehand that enlargements will most likely be required from the negatives he is producing, of course care will be exercised to produce the greatest amount of detail and sharpness that is possible, and in several branches of photography, such as engineering and architectural work, in which enlargements are so frequently required, this obtaining of the utmost amount of sharpness in the original is of the greatest moment, and it frequently happens, where circumstances permit of such being accomplished, where any important commissions for these large sizes are concerned, that it is wise on the part of photographers to discard any negative that may be on hand that does not possess the necessary qualities for enlargement, and proceed to make one specially for the purpose. A little extra trouble and money spent at this stage will save a heap of anxiety later on. The question is frequently asked, How much may any negative be stretched out in enlarging? To this no reasonable answer can be afforded. The writer possesses one negative, which contains the image of a steamer, taken by a drop shutter, when going at a fair rate of speed, that has yielded nearly one hundred six-foot enlargements, and the image of the steamer is not over three inches in extent. But this is an exceptional case, no doubt. Every negative has a limit, and once an operator places it in the enlarging camera, and projects its image on the screen, he soon sees how far it is advisable to work to.

In focussing, provided plenty of light be allowed to pass through the lens, by using it with its widest aperture and finally stopping down somewhat for exposure, the pilot print will show whether or not a sharp focus has been obtained; if not, another attempt must be made before placing the sensitive paper *in situ*; focussing, however, seldom causes any anxiety when a pilot print is run beforehand.

In placing the sensitive paper in position for exposure, a tin hood is used on the lens, in which is fitted a fairly deep canary glass, and if this is of the right tint a reasonable time may be occupied in fixing up the paper and seeing that the image occupies the right position upon it without causing any deterioration or fog; but it is, of course, wise to accomplish this part of the operation with as little delay as possible. A couple of minutes or so will do no harm with fairly dense images, but, if exceptionally thin negatives are being enlarged, it is prudent to insert a second sheet of yellow glass in the tin hood. Fog, however, seldom gives any trouble in enlarging when reasonable precautions are taken.

After a correct exposure has been timed, by means of running the pilot at three varying periods of time, the final exposure is made, and any shielding or dodging, so as to bring up one portion of the negative and keep back another, is performed by wafting a card at a fair distance in front of the sensitive paper, and, if vignettes are required, the vignetter is placed on an upright support a short distance in front of the lens, and moved backwards and forwards until the shading is seen to be as desired. Of course this has to be performed with the double sheets of canary glass in the hood to commence with, and care exercised until it is seen that the vignetter has been made to occupy the proper position between the lens and sensitive paper.

A delightfully soft blender is provided by utilising wooden cut-outs, or apertures, and these can be slid up and down a stiff rod, or attached even to a head rest, which will enable their being placed in any desired position and kept there during the time required for exposure. The wooden cut-outs may have small pieces of tin tacked on to their sides or edges. These little pieces of tin are easily bent round any upright, such as a stout wire or piece of the head rest, and then by pinching the tin it will grip the support and be held firmly in position.

A very handy little contrivance for holding a vignetter in position, between the lens and sensitive paper, when enlarging, is formed by using the upright rod of a microscope lamp, and sliding the cut-out, to which the tins have been applied, up and down, until it just reaches the right position. Some workers seem to shirk the vignetting of pictures in enlarging, and prefer to produce them in what is known as "solid" form, but the vignetting is quite easily performed if such a simple method of holding the vignetter as stated is resorted to, and in portraiture it is often a distinct improvement.

Before attempting to develop such large-sized pictures, special preparation should be made so as to work in comfort. A beginner at this class of work is very prone to engender more or less funk when developing his first monster, for there is no denying the fact that a certain amount of anxiety will animate any one not accustomed to developing very large pictures, but I have never known it to fail that any one, after having developed one or two large-sized exposures, begins to scorn small sizes in future, and infinitely prefers to do the "big ones." In fact, when care is observed, and everything necessary at hand, there is no real difficulty in the operation.

The main factors to be observed in development are the following: First have plenty of developer ready, and see that quite a plentiful supply of safe light is provided, so as to throw a sufficiency of light over the entire developing dish, and then have at least two good-sized tubs placed in position at the corner of the dish where it has been decided to pour off the washing water.

All being prepared, the nine-foot dish is placed upon a large kitchen table and several bucketfuls of clean cold water are placed in the dish, or

as much as will yield at least nearly a depth of an inch with water. The exposed roll is then taken to one end of the dish, and the operator handing over one end of it to his assistant, at the other side of the dish, while he holds the other at his opposite side, the roll is equally unrolled and the paper submerged in the water *slowly*, care being observed that no air bells get underneath. By *slowly* and deliberately unrolling the paper equally at both sides this will be avoided. When the entire length is submerged (of course sensitive side upwards), plenty of time must be given for the paper to become equally saturated throughout. This is important, for, if care be not observed at this stage, there will be a strong liability of causing marks, by unequal development, during the next stage of the operation. In any case it is a *sine-quâ non* that the entire sheet of paper must lie absolutely flat in the bottom of the dish. When the washing water is all run off after soaking, and prior to the application of the developer, four or five minutes may be necessary before the paper is equally saturated and expanded; then, by gently lifting the dish, the water is made to overflow into the tub that has been provided at one corner, and the whole dish is reared up on end for nearly ten minutes to drain off as much superfluous water as possible so as to ensure equal development.

If metal be employed, the plain solution is first applied copiously, and by rocking the dish and the use of a very wide camel's-hair brush it is made certain that every part of the surface has received the developer. This is then carefully poured back into the large wash basin, into which a small quantity of accelerator has been placed, and, when carefully mixed, the entire wash-basinal is deftly applied to the print, and the dish rocked and the solution guided over the entire surface by means of the brush. If the exposure has been right, the shadows or dark portions will come into view in about half a minute's time, and then the entire picture develop beautifully out, any parts that hang back being coaxed up with the brush, and, if necessary, a little extra soda or potash being applied.

If all goes well, the result is something that an operator may well feel proud of, and he is sure to give vent to his feelings by such expressions as "he's a beauty." When the developer is run off, the print is rapidly sluiced with water, to be followed with the fixing solution, all of which, in plentiful supplies, must be ready at hand, and no carelessness, even at this stage, must be allowed to intervene, for it must be seen that every portion is quite fixed. The washing is then finally performed, and the print drained and hung up on the sides of the dish when reared on end, for, say, twelve hours, till quite dry.

The mounting of these large prints is, of course, done upon cloth. Suitable cotton sheeting can be had from any large drapery establishment, and this is first soaked, and wrung out, in clean cold water, and nailed upon a stretcher until practically drum-tight. The dry enlargement is then placed face downwards, and, by means of a wet mop or sponge, a plentiful supply of water is applied to the back thereof, and, when the print is quite wetted equally throughout, a good supply of stiff and cold freshly made paste is evenly spread over its back, care being taken that the paste is quite free of any lumps by having pressed the same through a bag of coarse muslin. The print is then placed upon the stretcher and rubbed into contact, and set away to dry. When all has gone well it will dry up beautifully smooth and drum-tight.

The working up of these large-sized pictures in black and white requires a fair amount of patience, but it is really wonderful what an improvement can be effected with the exercise of a little determination and thought.

If metal has been used in the development, a little ivory black and Chinese white, mixed so as to yield the colour of the different densities it is desired to work up, will yield any depth, from the darkest shadow to the very verge of the high lights, and the picture should be placed under the light of the window in the same position as it is intended to occupy finally.

Three or four hours' steady work with the brush and the pigments named will work quite a transformation.

Any black spots or eyesores that may have to be removed are got rid of by touching them carefully with a finely pointed brush carrying a little solution of ferricyanide of potassium and hypo, and when they are white and dry they are easily coloured to the tint of their surroundings.

After a little practice, any one that at all cares for this class of work will begin to get quite fond of such, and will find himself imperceptibly leaning towards placing any amount of work on such pictures, and feeling quite sorry when he has no more difficulties to overcome.

Quite a volume might be written on the subject of working up in black and white, but the best advice I know of for a beginner is to begin in the simple manner I have stated, working up the dark portions first with the pigments I have mentioned, and he will find himself overcoming difficulties he may for years have deemed unsurmountable.

A. SCOTT.

#### BLACKIE'S METHOD OF GENERATING OXYGEN.

MR. W. BLACKIE employs a case fitted with a gas bag, the top of which forms a platform made hollow to hold water, the weight of which gives the necessary pressure to the oxygen in the bag. Guides are provided to keep the platform level as it rises and falls when the oxygen is admitted.

to or drawn from the bag. Upon this platform is mounted a hollow central pillar, fitted with a swivel head, to which are fixed a number of radial tubes or retorts, capable of revolving, gas-tight, around the central pillar, and at a sufficient height to allow of a heating lamp being placed under them. By this rotary movement the retorts are brought successively over the heating lamp.

The retorts are constructed of a thin cylindrical outer casing, enclosing a small tube arranged axially thereon. The ends of the casing are closed by discs, one of which is fixed on the central tube, and the other is loose, the whole being tightened up by means of a cap screwed on the end of the tube adjacent to the loose disc. Asbestos rings may be employed to make the joints. The usual oxygen mixture of chlorate of potash and manganese is used for generating the gas, but this mixture is pressed into annular cakes, which fit around the internal tubes of the retorts. By unscrewing the single screw cap at the end of the retort, the spent cake can be removed, and the retort charged afresh by the introduction of another cake, after which the retort is sealed by the screw

FIG 1

cap. The whole operation of discharging and recharging the retorts can be performed very quickly. The gas generated in the retorts escapes through perforations in the central tube, and passes into the hollow vertical pillar about which the retorts turn, and thence through the hollow platform, where the gas is cooled by contact with the water. Some of the gas passes direct to the jet, and the surplus finds its way into the gas bag. In case more oxygen is formed than the bag will hold, the platform rises until a relief valve therein is brought against an abutment, which opens the valve and allows the excess of gas to escape. When a further supply of gas is required, a fresh retort is brought into position over the heating lamp, and so on, until the contents of all the retorts are spent. A hood guards the flame of the heating lamp, and also fixes the retort under operation in position by dropping between flanges of the plate fixed on the heating lamp, the hood having to be taken off and replaced each time the retorts are moved. The central pillar unscrews at the base, for convenience of packing and to allow of filling the hollow platform with water.

"The construction of the retorts and their rotary movement about the central pillar form the chief features of my invention. In some instances I provide for moving the lamp along the retort to effectually heat the whole of the surface of the latter. The construction of the oxygen-yielding cakes in the form of annular rings is also very important, as it facilitates the decomposition of the cakes."

The inventor adds: "In a modification of my invention, I use one retort only constructed as above described, but of larger pattern, and I arrange it with a capability of sliding horizontally through a holder to bring the various parts of it successively over the heating lamp. I charge this retort with a number of short annular cakes of oxygen-yielding material separated by cupped or other suitable washers forming an

air space to prevent the transmission of heat from one to the other and the consequent firing of the cakes prematurely. As soon as each cake is spent the retort is moved by hand to bring another cake over the lamp.

FIG 2

"In order that my invention may be clearly understood, I have represented an apparatus constructed in accordance therewith in the accompanying drawings, of which

"Fig. 1 is a view from left-hand corner with part removed of the apparatus.

"Fig. 2 is a plan of the same.

"Fig. 3 is a longitudinal section of one of the retorts.

"Fig. 4 is a view of one of the annular cakes of oxygen-yielding substance.

"Fig. 5 is a longitudinal section of a larger-size retort showing one method of forming air spaces between the cakes of oxygen-yielding substance.

"Like letters of reference denote similar parts throughout the figures.

"c is a case for enclosing the apparatus and serving as a packing box therefor; part of the box is removed to show the expansible gas bag, b, for storing the generated gas. r, r, are retorts connected to the central hexagon socket, which revolves gas-tight, forming the swivel head, s, of the central pillar, p, supported on the hollow platform, p, which in its

FIG 3

FIG 4

FIG 5

turn is supported by the partly inflated gas bag, b. The weight of this apparatus on the gas bag gives a certain pressure to the contained gas, but for most purposes a higher pressure is required; this can be obtained by charging the hollow platform, p, with water. Attached to the case, c, are upright guides, g, g, for the purpose of guiding by the friction wheels, w, w, the upper part of the apparatus in its ascent and descent when the gas bag is being filled or emptied. l is the heating lamp capable of a movement along the slides, s, over which one of the retorts is placed.

"The gas generated in the retort directly over the heating lamp escapes through a perforation in the swivel head, *s*, into the hollow central pillar, *p*, on to the surface of the water contained in the hollow platform, *r*, thence up the valve pillar, *p*<sup>1</sup>, by the inlet, *i*, to the gas bag and the outlet, *o*, to the limelight jet. In case of there being more gas generated after the gas bag, *b*, is full, it is liberated by the relief valve, *v*, coming in contact with the abutment, *a*, by the rise of the hollow platform, *p*.

"The passage for the gas in the central pillar does not pass down into the water, but ends at its base, and the hollow platform, *r*, is only charged with water up to the dotted line (fig. 1), so allowing a passage for the gas over its surface, and the surface being large condenses any vapour and absorbs any impurities the gas may contain, without any fear of the water being forced into the retort by the back pressure of the gas in the bag, as it is likely to be in the ordinary way of washing gas. Suitable partitions may be fixed in the hollow platform, so making the gas take a sinuous direction and keeping it longer in contact with the water.

"Only the retort directly over the heating lamp is open to the passage in the central pillar, so allowing any of the other retorts to be opened if necessary for the insertion of a new cake, when the apparatus is at work, without the gas escaping. When the cake in the retort directly over the lamp is spent, the next retort to it is brought to its place over the lamp.

"Fig. 3 is a longitudinal section of one of the retorts showing the method of closing the ends; one end of the retort tube containing the cake is in contact with the asbestos ring in the fixed cap, *c*, the other end being in contact with the asbestos ring in the loose cap, *c*<sup>1</sup>, so that the act of tightening the screw cap, *c*<sup>11</sup>, on the stay tube, *t*, makes a gas-tight joint by pressing its cone into the seating, *s*<sup>1</sup>, at the same time tightening up the joint at each end of retort tube. The holes, *h*, *h*, are for the generated gas to pass into the stay tube, and so into the central pillar, *p*.

"Fig. 5 shows a larger size retort containing a number of cakes; under each cake a heating lamp could successively pass, so as to decompose one cake at a time, the cakes being kept apart by the cupped distance washers, *d*, so forming an air space; the confined air being a bad conductor of heat prevents more than the cake directly over the lamp from being decomposed. In some instances, in lieu of the distance washers, projections on the central tube might be used, or the cakes might be placed in a carrier with projections before being placed in the retort, so keeping them a distance apart."

#### STEREOSCOPIC EFFECTS: RALEIGH'S SYSTEM ON THE SCREEN.

The inventor, Mr. Charles Raleigh, says: "According to one mode of obtaining stereoscopic effects in the representation of moving objects, instead of employing a stereoscopic camera and producing two distinct series of pictures, the two series being respectively taken from points of

view at a greater or less distance apart, I employ a single-lens camera, arranged in any of the modes commonly adopted for taking in rapid succession a series of photographs of a moving object. Having printed or otherwise reproduced the series of pictures in duplicate, I pass the two series side by side rapidly through a stereoscope. Although the two series of pictures are identical, identical representations of the object are

not under observation at the same time; in other words, the one series is arranged slightly in advance of the other, according to the direction of movement of the object photographed. For example, the first picture in the one series may accompany the third picture in the other series; the second may accompany the fourth, and so on, the relation of the corresponding pictures in the respective series being, however, varied according to the degree of relief desired, the lapse of time between the exposures, the speed of the moving object, the direction of motion, and the distance of the object from the camera. Fig. 1 of the accompanying diagrams illustrates this method of arrangement, picture No. 1 in the right-hand series accompanying picture No. 3 in the right-hand series. In fig. 2, picture No. 1 in the right-hand series accompanies picture No. 2 in the left-hand series.

"According to another mode of accomplishing the same object, I employ a single series of pictures, but expose them in a stereoscope arranged in

Fig 3.

Fig 4.

such a manner that the eyes of the observer, looking through the two lenses of the instrument, see the first and the third pictures at the same time, then the second and the fourth, and so on; or the first and the fourth, the second and the fifth, and so on, according to the conditions before referred to as rendering variation in this respect desirable. The former of these two methods is illustrated in fig. 3 of the accompanying diagrams, pictures Nos. 1 and 3 being presented simultaneously. The next pair to be seen would be Nos. 2 and 4.

"The diagram (fig. 4) illustrates a similar method of working, in which pictures Nos. 1 and 2 are seen together, then Nos. 3 and 4, and so on.

"From the foregoing it will be readily understood that, in order to produce from a series of representations of a moving object any given stationary picture, the subject appearing in relief, it is only necessary to select two of the pictures more or less removed from one another as regards their proper positions in the series, and to expose the same to view in a stereoscope."

#### THE PRESENT AND THE FUTURE OF MEANS OF ILLUMINATION.

We are at present entirely dependent upon solid bodies rendered luminous by heat for giving us light, and until very recently the high temperatures necessary to make solid bodies enable us to see were procured solely by chemical action, viz., by the union of carbon and hydrogen with oxygen, the chemical action, in short, which we call combustion. It is only quite of late years that we have utilised the heat developed in a conductor by its resistance to the passage of a current of electricity through it to produce light. Now, however, says Mr. Herbert Robson in *Invention*, all our so-called electric lighting is obtained by that very process. Hence, if we designate the flame of the electric arc, or the glowing spiral of a Swan lamp, an electric light, we should, to be consistent, call the flame of a candle or of a gas jet a chemical light. In the first artificial light the necessary heat was, no doubt, procured by friction, *i.e.*, by the conversion of mechanical force, and, although the process nowadays is somewhat more complex, it is nearly always the case that we begin with mechanical force still. To get an ordinary light we strike a match, and get heat. The heat gives chemical action. That gives more heat, and enables the lighted match to start chemical action between the oxygen of the air and some combustible substance such as coal gas. Even if we do not light a match, we use some burning body which has been lit with one.

The proximate cause, then, of all our present illumination is heat, and the penultimate cause is either chemical action or electricity, in most cases the former, while the ante-penultimate cause in 999 cases out of 1000 is mechanical power. The electric light is very rarely, and never except in a laboratory, produced by the chemically generated electricity of a battery, but is the result of the mechanical power exerted by a steam, gas, or water-driven engine upon a dynamo. This, again, in the ultimate analysis depends upon the power of terrestrial magnetism. The driving power of the dynamo only supplies the mechanical force, and not the resistance which converts the force into electricity.

The great points to be borne in mind are, firstly, that the light is got by the conversion of some form of energy which is not light; and, secondly, that the process of conversion is an indirect one, the energy being first converted into some other form which is not light. The next advance will, no doubt, be to convert some form of energy other than light directly into light without making it into other forms of energy.

different from light as preliminary steps. When this is done it will be a feat far surpassing the discovery of the now completely vulgarised electric light. At present strenuous efforts are being made to obtain light from electricity without first making heat, but there is no known reason why it should not be got direct from energy generated by nature, instead of by artificial methods. There is plenty of heat, electricity, and chemical and mechanical forces round about us which were made without fire bars, bottles, or retorts, or brass balls, wires, or porous pots, and nature interchanges them one for another without any of our scientific paraphernalia of brass and glass. Enormous amounts of every kind of energy are radiated to us from the sun, for example. It may be we shall be able some day to imitate nature, and to get, for instance, "wireless" telegraphy really without wires, which we have not got yet. The next step, however, will probably be to save the intermediate conversion into heat when light is obtained from electricity, and there is at least a chance that the writer of these lines may live to see that done.

#### THE NOTTINGHAM INCANDESCENT LIME-CYLINDER SYNDICATE.

THE prospectus of this Syndicate is in circulation. The capital is 8000*l.*, and the Directors are Messrs. F. Brown, C. W. Locke, J. J. Smith, and J. H. Hutchinson. The following are extracts from the prospectus: The difficulty of obtaining a regular supply of reliable and truly turned lime cylinders of such a quality as will stand the severe test of the improved jets lately introduced is admitted by all opticians, operators, and lecturers. This requirement the Syndicate is now in a position to meet. The Syndicate has up to the present moment secured the businesses of the Incandescent Lime Company, of Nottingham, and Carter & Co., of London, and is negotiating for the purchase of other similar businesses. Orders have been already promised from some of the leading opticians, amounting to an average of 100 gross per week. Subscribers are invited to call and inspect the lime in the rough, and to see it chipped and drilled in their presence. The cylinders so prepared they are at liberty to test on any jet now before the public. The quality of the lime has been subjected to the most severe tests by some of the most well-known members of the trade.

#### THE LANTERN IN THE SCHOOL: HER MAJESTY'S BIRTHDAY CELEBRATION IN THE LONDON BOARD SCHOOLS.

THE Bath-street Board School, City-road, St. Luke's, being the first school in London opened by the London School Board, it was thought by the teachers that, considering the great advances which had been made in education during Her Majesty's reign, it was fitting that her eightieth birthday should be celebrated in such a manner as to impress upon the children the great happiness which had accrued to the nation owing to the long and peaceful reign of Her Majesty. Accordingly, following the instructions of the Board, the children of all three departments, numbering over 1500, were assembled in three relays in the large hall of the boys' department, where a beautiful set of over a hundred lantern slides, specially prepared by the head master, Mr. G. J. Clarke, formerly Honorary Secretary of the North London Photographic Society (now defunct), were exhibited to the children and descanted upon by the teachers. The slides included portraits of Her Majesty at various ages, of the other members of the Royal Family, of scenes in Her Majesty's private life, and many views of public functions, &c. At the end of the entertainment the children sang "God Save the Queen," and the head master addressed them upon the loyalty which was owing by all to so good a sovereign, and the whole school, teachers and children, then joined in three cheers for the Queen, finishing by the head master sending a telegram in the name of the teachers and children of the first Board School opened in London to Windsor Castle, offering their loyal congratulations to Her Majesty upon her having attained her eightieth birthday.

#### ACETYLENE LAMP EXPLOSION.

AN accident, illustrating the need for care in the use of calcium carbide for producing acetylene gas, occurred at Penicuik, near Edinburgh, recently. A young man, home for a holiday, had with him a bicycle acetylene gas lamp, which excited the interest of one of his brothers at home, who determined to make a similar one for household use. Procuring a perfume spray producer, he showed some ingenuity in adapting it for his purpose. When the lamp was lit there was a slight explosion, which was supposed to be due to a small leak near the top of the lamp. This having been securely closed, he determined to have a second trial. He had just retired to his bedroom for the night when the family were aroused by a violent explosion, and on the father going into his son's bedroom he found it in confusion, the lamp being blown to fragments, while his son was bleeding from severe wounds about the right eye. After being attended to by a local doctor, he was taken to the Royal Infirmary, Edinburgh, where the case was regarded as a serious one. An

operation was successfully performed, and he is now progressing favourably. It is probable that the leak which was supposed to cause the first explosion really acted as a safety valve, and made the explosion slight. Probably the young experimenter did not realise that the air in the perfume bottle would take some time to squeeze itself through the orifice of the spray-producer, and by prematurely applying a light the mixture of air and acetylene gas was exploded.

A GERMAN inventor has devised a curious display apparatus, which consists of a mirror having its rear face silvered to such a degree as to render it capable of reflecting objects. A picture is secured in the rear of the mirror, and under ordinary conditions it is indistinguishable through it. An electric light is mounted in the recess at the rear of the mirror, which can be lighted and extinguished at will. When the current is turned on, the picture on the back is brought into view, and, as the light may be flashed intermittently, a curious effect is produced.

THE energy of Röntgen rays has been investigated by the Rev. Alexander Moffat by measuring the luminous energy given out by a fluorescent screen when exposed to the rays. This energy is, of course, very small, but it must be remembered that it only represents four per cent. of the energy impinging upon the screen, and also that the interval between two successive X-ray discharges is about 1000 times the period of time covered by the discharge itself. Allowing for these facts, it appears that, if the Röntgen rays were continuous instead of intermittent, they would exert an effect 500 times greater than sunlight when falling perpendicularly upon a surface.

THE *Militär-Wochenblatt* publishes a description of a portable acetylene field searchlight, invented by Lieut. von Kries, of the German army. It is intended to be used at night in searching for the wounded on the battlefield. The acetylene developer, which a man can easily carry on his back, is constructed to contain rather more than 2 lbs. of calcium carbide. This is sufficient to produce a supply of gas capable of maintaining a light of from 50 to 60 candles for eight hours. A special arrangement of two concave parabolic mirrors increases the power of the light by reflection and concentration to about 100 candles. The light, with the reflector, is placed on the top of an upright rod, which forms a pivot upon which the light can be turned in any required direction. The effective radius is about 100 yards. A metal tube connects the light with the developer. The latter is automatic in its working, and all danger of explosion is fully guarded against. The light can, of course, be used for other purposes than that for which it is especially designed.

ONE has only to go through Dr. Gates' laboratory to see that he is a man of many and interesting ideas. The writer had the pleasure of going through this place recently and of beholding some of the mechanical apparatus there used in connexion with scientific experiments. These investigations take in, with other matters, electricity, music, and X-ray photography. In the electrical field Dr. Gates has, I am informed, made some important discoveries. He has also used solar heat in connexion with storage batteries, obtaining interesting results. At the laboratory location—Chevy Chase, near Washington, D. C.—a large building is being finished, in which will be placed musical instruments, such as pianos and organs, and experiments in sound will be carried on here. It is a well-known fact that some musical notes require more force than others to produce, and that, by properly gauging this force, not only is energy saved, but correct modulation and expression are gotten. This will form part of the investigations in the musical department. Of course, all such work is of interest, but that which Dr. Gates has already accomplished in connexion with micro-photography, with his invention, the mega, or double microscope, should take precedence in the scientific field of his research. With this apparatus, in which one microscope enlarges the image magnified by the other, the result being cast upon the sensitive plate in a camera, objects that are normally invisible are made to appear plainly to the observer, in many instances showing wonderful detail before unknown. The mega microscope has given magnified photographic results of 360,000 diameters, and its possibility, according to its inventor, far exceeds this, running up into millions of diameters. Dr. Gates says, in speaking of his work in this particular, that, with a  $\frac{1}{4}$ -inch objective in the first microscope and a  $\frac{1}{8}$  inch in the second, he has resolved markings and details in microscopic objects which could not be resolved with the best  $\frac{1}{16}$ -inch apochromatic instrument of high aperture, and that when higher objectives than a  $\frac{1}{8}$  and  $\frac{1}{16}$  are used, the eye no longer sees the image, but the sensitive plate comes to the aid and photographs the otherwise invisible image. In describing his photo-micrographic apparatus Dr. Gates says in part in a published article: "I have arranged to exclude from the interiors of the microscopes and camera all dust particles and aqueous vapour globules. The light can act cumulatively, hour after hour and day after day, if necessary, and the photogenic changes made on the sensitive plate will result wholly from the action of the image. From some tests already made I think I am safe in saying that, owing to this device, I shall be able to photograph with less than  $\frac{1}{100,000}$  part of the intensity of light formerly considered necessary."—"J. E. P." in *Anthony's Bulletin*.

### LANTERN MEMS.

STEREOSCOPIC radiographs were last year produced by Mr. Mackenzie Davidson, M.B., by means of two large photographs taken from two different points, and viewed through a large Wheatstone reflecting stereoscope. This year, at the Royal Society's *Soirée*, he exhibited in operation an apparatus to enable Röntgen-ray shadows to be seen in stereoscopic relief on a fluorescent screen. Persistence of vision is relied on, and two X-ray illuminated tubes are so placed that the hand or other object is seen on the screen, first with one eye and then with the other. A rapidly rotating disc, having two apertures so placed that they alternately cover and uncover each eye is used, and when these alternations are more than ten per second, the impressions are continuous, and the shadow of the object is seen in stereoscopic relief.

CAPITAL results were obtained, using first a skeleton hand and arm for the object, then a living hand, which was in perfect relief, and showed the observer at once whether the palm or back of the hand was towards him as the demonstrator reversed it. For surgical work this system will be invaluable, especially in field hospitals, as the surgeon can exactly locate any object, and mark the exterior surface of the limb from different points of view, and, if necessary, direct in technical language the exact depth necessary for the incision, while another surgeon operates. Many other objects were shown, and especially stereoscopic was a steel hammer, which stood out in the air, and showed the point or large end towards the eye as reversed.

A CLEVER feature of the apparatus was the method by which the two X-ray tubes were controlled. They were each illuminated by a coil having a mechanically driven contact-breaker, each of which acted alternately, as the right or left eye was uncovered by the rotating disc, and, both being driven by the same motor, the illumination of tube and rotation of disc could be exactly timed. As the frequency of these illuminations and obscurations was more than ten per second, persistence of vision resulted, and a continuous illumination of an apparently solid object seen in space was what the observer saw.

SOME fine specimens of the trichromate photographic transparencies were exhibited on the same evening by Mr. Saville-Kent

as lantern slides, stereoscopic, and in half-plate size, which showed that, in careful hands, this process, as suggested by Clerk-Maxwell and worked upon by Ives and others, could produce not only charming, but practical results as records. An interesting diffraction-colour photograph was shown for Mr. R. W. Wood, of the University of Wisconsin, by Professor Boys. For the apparatus a simple arrangement was provided. The edge of the flame of a bat's-wing burner served to illuminate a lens, to the opposite face of which a very faint photographic transparency was fixed. This was of a coloured window, and a little way in front—about one foot—was placed a slit, through which the transparency was to be viewed, and, on the eye being placed at this slit, the colours came out on the transparency. The photograph was taken through three-colour screens and the negatives superposed, before development, by ruled gratings of different pitches, so as to get the correct length wave for the red, green, and blue-violet. The transparency was taken from these negatives by contact printing, and just at the right position the correct colours were seen; but, if the head and slit were moved sideways, the colours changed, for one of the spectra was out of range, and the result given was from two of the screens only.

By the courtesy of Professor Vivian B. Lewes, I am able to answer your correspondent, "Veda," as to the colour of some residues of calcic carbide he sent to the office of THE BRITISH JOURNAL OF PHOTOGRAPHY, contravening, as he thought, the statement made in the Society of Arts lecture. Professor Vivian B. Lewes, who was called abroad after the matter was put before him, and has only just returned, says: "I have examined the sample of residue which you sent me, and it is as good an example as you could find of the results of overheating in a generator, the carbon in it having been nearly all deposited by the decomposition of acetylene through undue heating, and it is not in any way due to the carbide used."

G. R. BAKER.

### ON THE CONSTRUCTION OF CONDENSERS FOR ENLARGING AND PROJECTION APPARATUS.

THE condensers for enlarging and projection apparatus are used to concentrate as much of the light rays as possible on to the object to be projected, whether this be a negative or positive, to evenly illuminate the same, and to transmit the rays which illuminate the object to the objective which projects the enlarged image.

The requirements for the construction of a condenser are that the bundle of rays falling on it should be so refracted by it, that on the one hand the object placed against it should lie within the refracted bundle, and on the other hand that the refracted light cone should have as small a section as possible at that place, so that it passes completely through the objective, and that none should be stopped by the lens mount. Although not strictly so, this requirement is approximately fulfilled when the luminous point and the nodal point of the objective are conjugate foci of the condenser.

In any given case, therefore, the refractive power of the condenser is absolutely fixed.

The simplest and most usual case is that a condenser is constructed of two plano-convex lenses of equal size, with their convex surfaces towards one another. Between them, if their size is to be entirely used, the bundle of rays must be parallel to the axis, so that the luminous point must be at the focus behind the back lens of the condenser, and the focus of the front lens fall in the objective.

The question whether a condenser is better composed of (2) or (3) lenses has been often raised, and this I propose to treat of here.

It must be first noted that these two kinds of condenser can only be compared with one another when they are of equal focus; and it is most probable that the different views which have been so often advanced have arisen from this not being the case. It certainly cannot be denied that a weak two-lens condenser gives a considerably stronger illumination of the image circle when a third lens is added to it next the light than without this third lens, as by this the total focus is shortened, and consequently the source of light is brought nearer, and the angle of light from the luminous point is increased.

The important question now arises whether the same end could not be attained if, instead of adding the third lens, the two lenses, or perhaps only the back one, were made stronger.

The remark has been frequently made that two-lens condensers are quite as good as a triple, since the gain in the light angle, and the consequent increase of light by the addition of the third lens, is again lost by the reflection from the surfaces of this lens and by the absorption in its mass.

In order to test this question one must clearly determine what is this loss.

The loss of light by reflection can be accurately determined by Fresnel's law of reflection. It is dependent on the angle at which the rays strike the surface and on the refractive index of the glass. The incident angles are different the further one gets away from the middle of the condenser and depend upon the curvature of the surfaces. On the latter ground, where no special construction is being considered, one must confine one's attention to those rays which lie in the optical axis, and thus strike all surfaces at no angle. The middle of the image must thus alone be considered.

If the brightness of the incident light = 1, the brightness, with right angle incidence, of the rays which go through the glass surface is—

$$J_1 = 1 - \left( \frac{n-1}{n+1} \right)^2$$

in which  $n$  = the refractive index of the glass.

From this it is obvious that for various kinds of glass or for various amounts of  $n$ —

with $n=1.5$	1.6	1.7	1.8
$J_1=0.960$	0.947	0.933	0.918

This loss factor ensues with each surface, so that we have—

with $n=1.5$	1.6	1.7	1.8
for one lens $J_2=0.92$	0.90	0.87	0.84
„ two lenses $J_3=0.85$	0.80	0.76	0.71
„ three „ $J_4=0.78$	0.72	0.66	0.60

There has been entirely neglected that the light reflected from the second surface within the lens may be in part reflected back by the first surface and thus be used for illuminating, still this is treating of comparatively small quantities of light which have a focus beyond the source of light, and therefore are rather harmful than useful.

Since the refractive index of most of the lenses used for condensers varies between 1.5 and 1.6, the loss of light by reflection, taking the former index  $n=1.5$ , would be—

$$J_4 = 0.825 \\ J_6 = 0.75$$

and the brightness of the triple lenses compared with that of the two lenses would be as 0.75:0.825, that is to say, it would be about ten per cent. less with triple than two lenses.

As regards loss by absorption, it may be assumed to be equal for the two kinds of condensers if the total focus of the two condensers is assumed to be the same; for with this assumption, which is essential for comparison, the lenses of the triple condenser must be much thinner than with the double, so that the total thickness of the two will be about the same.

One advantage of the triple over the two-lens condenser, of equal total focus, must be mentioned, and that is that the optical work is divided over a greater number of surfaces, in consequence of which each surface

has a lesser curvature, whence less spherical aberration is caused; therefore the evenness of illumination, particularly at the margins of the field, will be improved, so that lenses of smaller diameter may be used.

From the foregoing considerations it is obvious that a triple condenser gives a better illumination than two lenses, if it is stronger, that is to say, has a shorter focus; but that, with equal foci of the two constructions, an important advantage of the one over the other can hardly exist.

Dr. HUGO KRÜSS.

## A LANTERN-SLIDE COMPETITION.

THE Association Belge de Photographie has announced an international competition, the slides for which must be sent in by October 15. There are three classes: Pictorial, Scientific, and Architectural. The sizes are restricted to 8×8 and 8½×10 cm. Further particulars may be obtained from the Secretary, 97, Avenue Brugmann, Brussels. The *Photographische Rundschau* complains of the stipulations as to size, and sees no reason why other nations should be precluded from improvement if the English stubbornly decline to adopt a better size. By this, of course, is meant the German size, 9×12 cm. From a discussion at the Vienna Camera Club, we gather that Dr. F. Hermann has advocated 9×12 cm. in the organ of the German and Austrian Alpine Club as a standard size for an exchange of Alpine lantern slides. The President of the Stereoscopic Section of the Vienna Camera Club (Herr Beck) makes a vigorous reply, and pronounces emphatically in favour of the English size. The *Rundschau* bases its chief argument against the English size upon the greater brightness of the image obtained with a larger plate. Against this we would place Herr Beck's remarks: "A not unimportant argument in favour of the size 8.2×8.2 cm. is, that slides of 9×12 cm. require larger lanterns and larger condensers, and it is well known that the latter gives less light with the same illuminant." Herr Beck also mentions the lower price of the plates, and we might add the difference in weight and the saving of carriage where slides are sent from place to place for exhibition.

## COLLODION LANTERN SLIDES FOR AMATEURS.

THE collodion slide is not so difficult to make as the amateur imagines, says Mr. F. Ivins in the *American Journal of Photography*, though not by any means as conveniently made as the ever-ready dry slide by contact printing. A camera is necessary, of course, and I presuppose the amateur knows how to manipulate the wet-collodion process, and I shall merely give formulae which I have found to work admirably.

The silver bath should be forty grains of nitrate of silver to the ounce of distilled water, made acid with pure nitric acid and thoroughly iodised. A bath which has taken up considerable alcohol from previous use is much to be preferred to a new silver bath.

The formula I have found best was recommended to me by Mr. William H. Rau; it is composed as follows:—

Alcohol .....	1 ounce.
Ether .....	1 "
Best gun-cotton .....	4½ grains.
Ammonium iodide .....	5 "
Potassium bromide .....	2½ "

In making the collodion I first measure the alcohol, then dissolve the iodide of ammonium in it. Grind the bromide of potassium in a mortar, adding a few drops of water. Add the alcohol containing the iodide gradually to the contents of the mortar, grinding constantly until all the bromide, or nearly all, is taken up.

Transfer the clear solution to a bottle.

Next measure out the ether and add it slowly, shaking the bottle by a circular motion until all is mixed, then add the cotton and set aside to ripen, which will require four or five days. It should have a deep sherry-wine colour. If this colour is not obtained, which happens sometimes by reason of the kind of iodide used, add tincture of iodine until the desired colour is secured.

In coating the plates use a thin flow of collodion, and, when the plate is well set and tacky, dip in the silver bath, where it must remain, moving it at times, until all greasiness disappears.

Give very full exposures; never undertime a wet slide.

Develop with the following:—

Water .....	16 ounces.
Protosulphate of iron (clear crystals) .....	1 ounce.
Acetic acid (No. 8) .....	4 ounces.
Honey .....	2 "

The image will come up gradually; let it develop until all the detail

comes up, but do not let the slide get any density by the development. Wash well under the tap and intensify as follows:—

a	Pyrogallic acid .....	24 grains.
	Citric acid .....	24 "
	Acetic acid (No. 8).....	$\frac{1}{2}$ ounce.
	Water .....	24 ounces.
b	Nitrate silver.....	40 grains.
	Citric acid .....	10 "
	Water .....	8 ounces.

Take of (a) in a glass sufficient to well flow the plate, and add to it a few drops of (b); pour over the negative, return to the glass, and watch the progress of intensification. If necessary, repour with the intensifier and continue the operation until the slide has reached the proper density, remembering that it loses scarcely anything in the fixing.

Wash well before fixing to prevent stain from the combination of the silver and pyro in the hypo.

The slides so made are the finest I have ever seen, even if I do say so myself, and I think those who try it successfully will agree with me in my decision. There is a beauty, clearness, and a wealth of shadows secured which have made Mr. Rau's lantern slides so celebrated, and the only ones on the commercial market that are equal to the renowned Levy or Laschenel slides of Paris, which are made upon albumen plates. Generally the tone of the slide after intensification is pleasing enough and needs no change, but sometimes from slight errors in exposure, or it may be from the character of the negative employed in making the slide, a modification of the tone is necessary.

I have found palladium or platinum the most pleasing toning agents, especially the latter if one desires a black tone; palladium gives a beautiful purplish-black. Both toners should be used very dilute, the toning being carried on in a shallow porcelain or glass dish, and the solution kept in constant motion like the development of a dry plate.

If used too strong, the toning goes on too rapidly and extra intensification is produced, and sometimes the shadows are clogged.

Platinum has more tendency to do this than palladium.

Platinum is best employed in the following manner, which gives a most beautiful warm, brilliant, black tone: One grain of bichloride of platinum in twenty ounces of water; neutralise it with pure carbonate of soda, and then slightly acidify it with chemically pure nitric acid. Proceed in the toning as above.

#### ACETYLENE GAS.

On account of its brilliant illuminating powers, and the pure white light which it gives, approaching more nearly to sunlight in its effects than any other artificial light invented up to the present time, acetylene has come largely to the front, especially among photographers, during the last few years, and of course, as in all cases where scientific or chemical reactions are concerned, the people who use it are generally in almost absolute ignorance of those reactions, and consequently some accidents have occurred, and acetylene has fallen somewhat into bad odour with the Government and fire insurance companies. As is usual in such cases, most if not all these accidents might be prevented with a little care. All, or nearly all, innovations meet with a certain amount of opposition, and when that innovation is attended with even a slight amount of danger, that opposition is intensified. Every kind of illuminant is attended with some danger, but with ordinary care this is reduced to a minimum, and then the prejudice gradually dies away. Coal gas is almost universally used now, but when first introduced many people would not have the pipes laid close to the wall, as they imagined that the flame travelled along inside the pipe, and that the latter was liable to get red-hot and thus cause a fire, while Sir Humphrey Davy proved that flame will not travel through an open pipe, much less a closed one. Gasometers, again, were viewed with alarm at first, as people were afraid they might catch fire and explode, this, again, being a physical impossibility, as coal gas cannot explode unless mixed with at least seven parts of air. It will be very unfortunate if the progress of such a good and useful illuminant as acetylene is retarded by carelessness and ignorance of its nature and properties.

Acetylene as an illuminant is not by any means a new discovery, having first been discovered accidentally by Edmund Davy during some chemical experiments rather more than sixty years ago, when he produced a compound of potassium and carbon which, on the addition of water, gave a highly inflammable gas, which he is believed to have called "Klumene." Nothing much seems to have been done with this until 1859, when Berthelot, the celebrated French chemist, produced a gas by passing a current of hydrogen through the electric arc, and, as on analysis he found this greatly resembled acetyl in its chemical properties, he called the gas acetylene, the name by which it is still generally known.

We are indebted to the great German chemist, Wöhler, for the next step onward in the production of acetylene gas. He found that, by fusing together a mixture of zinc, calcium, and carbon, he produced a compound which, on the addition of water, gave acetylene gas, and thus formed the first calcium carbide. All these experiments and discoveries, although useful from a chemical and scientific point of view, were no good for the

production of acetylene upon a commercial scale, on account of the difficulties attending the manufacture of carbide, and the consequent high price, and it was not until 1889, when Willson in America and Moissan in France, independently and accidentally, discovered that, by fusing calcium oxide and carbon in an electric furnace, calcium carbide was produced, and made acetylene gas a commercial possibility. Carbides of other metals may be produced in this manner which also give acetylene by decomposition with water; but, as calcium is the cheapest and most plentiful, besides being found in a fairly pure state in the various calcium salts, more particularly in lime and chalk (carbonate of lime), it has naturally been chosen for the commercial production of carbide. Acetylene, the chemical formula of which is  $C_2H_2$ , is a clear, colourless gas, which, when the carbide is pure, contains as much as 92½ per cent. of carbon.

The burners used for acetylene require to be constructed somewhat differently from those for coal gas, or when they get hot they cause a deposit of carbon in the apertures, thus stopping the flow of gas. On account of the high illuminating power of acetylene, the apertures of the burners are not usually made very large; the largest, as a rule, do not pass more than 1 cubic foot of gas per hour, giving at this rate a light of about 50 candle power, while coal gas burnt at the standard rate of 5 cubic feet per hour gives a light of about 16 candle power, acetylene thus possessing about fifteen times the illuminating value of coal gas. A great advantage with acetylene is the small amount of oxygen necessary for its combustion, it only requiring about one-eighth that of coal gas. The products of combustion also are not nearly so injurious. The acetylene flame is likewise much cooler than the flame of coal gas under ordinary conditions, though, if burnt with its own volume of oxygen, it almost rivals the heat of the electric arc, which produces the highest temperature known at present. At first sight it might seem an easy matter to produce a good and portable acetylene lamp, but this is not altogether the case, several of those in use, for bicycles in particular, having very grave faults. In one type the water is at the top, this being a disadvantage, as the heat quickly evaporates the water, and, where the lamp is required for a length of time, the water gives out, and, if as often happens in dry weather in the country, it is difficult to procure a fresh supply; also, should the water get hot enough to drive off the carbonic acid gas contained in hard water, the precipitate may clog the fine water tube and prevent the lamp acting. With this kind the flame is regulated by the amount of water allowed to fall upon the carbide, which is rather a good arrangement, but in another type the flame is regulated by a tap in the same manner as ordinary coal gas; and upon the face of it would seem a better way, but upon examination we find that a vent hole is left in the generator, so that an excessive pressure may not be attained, and any gas not used escapes into the atmosphere, a very bad thing when indoors. Undoubtedly the best method is to have a kind of gasometer where the gas can accumulate if it generates more quickly than it is used. The drawbacks to this are the greater space required for the apparatus, and the risk of explosion if a greater pressure than 30 pounds per square inch is attained unless the gas can be kept cool, though, if the apparatus is properly designed, too great a pressure should automatically shut off the water, and thus obviate any risk. Unless the gasometer style can be adopted, the flame should always be allowed to burn out of its own accord, or the gas will escape and explosions may follow if in a building or room where it cannot get away. Fortunately the very strong and disagreeable smell of acetylene (1 part of acetylene in 10,000 parts of air being noticeable) indicates its presence very quickly, so that the risk of explosion is not nearly so great as with coal gas, but in any case it is better not to allow it to escape. Acetylene gas has a longer range of explosibility than in coal gas, as it explodes when a mixture of 1 part gas to 20 of air is reached, while coal gas will only explode when the mixture contains 1 part of gas to 15, and, in rare cases, 16 of air.

Acetylene is known in chemistry as ethine, and is generally found to a small extent in coal gas, it is also produced in all cases of incomplete combustion, notably when a Bunsen burner lights back; this was originally thought to be very poisonous, but has been proved not to be so.

Acetylene,  $C_2H_2$ , is produced, for commercial purposes, by the action of water,  $H_2O$ , upon calcium carbide,  $CaC_2$ , by double decomposition, thus:—

Calcium carbide is manufactured by fusing lime or chalk with carbon, in the form of coke. This fusion requires a very great heat, which at present can only be attained in the electric furnace. The demand for calcium carbide is increasing, and is likely to increase, and this opens out a new source of revenue for electric-light installations during the daytime, when little current is being used, as no means other than the electric furnace have yet been found of producing calcium carbide, which, as usually manufactured upon a large scale, is formed by feeding a mixture of three parts coke and two parts lime into the furnace, where it quickly fuses; these proportions are found most suitable for working; but, as the carbide is a chemical compound, no matter in what proportions the two ingredients are mixed, the resulting carbide is always the same, as its formation is governed by the well-known chemical law of combining proportions.

If the temperature is kept at the freezing point of water, acetylene

may be compressed to a liquid by a pressure of about 325 lbs. per square inch, and then becomes a limpid fluid, which is being used for lighting trains and buoys.

Calcium carbide, being of a very hygroscopic nature, must be kept in air-tight tins or boxes, or otherwise it quickly deteriorates by evolving gas, and, on account of the carelessness displayed in handling and storing it, a Home Office order has classed it among the "dangerous" goods, although by itself it is not an explosive compound.

Much trouble has been caused by carelessness in filling the generators too full of carbide. This is a very serious matter, as carbide in decomposition increases almost 100 per cent. in bulk, therefore no generator should be more than half filled with carbide, to allow for this expansion, or the generator may burst. One pound of carbide requires about 8½ fluid ounces of water for its decomposition, and this should produce 5 cubic feet of gas, if the carbide is pure, which is the quantity generally guaranteed by British carbide-manufacturers to be obtained from 1 pound of carbide. To be used economically, no more carbide should be wetted than is sufficient to generate the amount of gas required, unless the gas can be set red, as the carbide will absorb water from the residue of lime, and continue to evolve gas, thus entailing loss.

Acetylene is nearly a pure gas, free from sulphuretted and phosphoretted hydrogen, and the spectrum of it greatly resembles the solar spectrum; consequently it is very suitable for, and has been largely used during the last few years in photography, and careless photographers with imperfect apparatus, if they investigated the matter, could, no doubt, trace the deterioration, and in some cases spoliation, of their chemicals, plates, &c., to the fact that they have paid no attention to their generating and lighting apparatus, and consequently they have allowed the gas to escape and spoil their stock, as, although acetylene is much heavier and denser than coal gas, and thus cannot escape so fast, besides which it is purer, chemicals, &c., left in a constant atmosphere of acetylene are bound to deteriorate.

Acetylene is very suitable for photographic lantern and dissolving-view work, being much more portable and convenient to use than the oxyhydrogen, or, as it is more commonly called, limelight, and it has the additional advantage of occupying less space, besides being more economical.

One very great advantage of acetylene is its portability and the small plant required to form the gas, for, as the latter is formed synthetically by the nascent union of its elements, it is produced in an almost pure state, consequently it does not require the elaborate and expensive purifying apparatus necessary for gases obtained by the destructive distillation of carbonaceous compounds, and in places where it would be difficult, if not almost impossible, to obtain coal gas or electricity, acetylene may be used with advantage, although at present it is somewhat dearer than these in towns; but, as the demand for calcium carbide increases and the methods of production improve, a great cheapening of the carbide may be expected, and acetylene may eventually prove the cheapest as well as almost the best illuminant, for by its aid delicate shades of colour may be noticed—an advantage possessed by hardly any other illuminant; this should prove especially useful to drapers and others for matching and detecting shades of colour, and to photographers for toning after dark, as, although by practising in a particular light a fairly even tone may be obtained, it is not possible to get the tones so exact except by daylight or by the light of acetylene, which may also prove a great boon to photographers in another way, as, owing to its rays having a similar actinic effect upon printing-out paper to that which sunlight has in the winter time, when the weather is foggy and dull and printable daylight is reduced to a minimum, prints may be made by its aid, and to a busy photographer, at his wife's end to produce photographs to time under present conditions, the advantage cannot be over-rated. Owing to the extra cost, it is very unlikely to be used when daylight is available, but, as very often in the winter time this is not to be obtained, the probable increase of business, coupled with greater freedom from worry, may be set against the extra cost. The writer's experiments in this direction have not been sufficiently extensive to give an idea of the probable cost, which may prove rather high, as a strong light is necessary, and, of course, the stronger the light, the greater the cost; but, on the other hand, the stronger the light, the more photographs may be printed by its aid. It will be gathered from this that printing-out-paper must not be left exposed to the rays of acetylene or discolouration will take place.

For working economically, the waste residue of lime should always be cleared from the generator before putting in a fresh lot of carbide.

During the decomposition of the carbide the generating chamber gets very hot. Chemists explain this by the fact that, as such an enormous amount of heat is absorbed in the manufacture of the carbide, a certain proportion is given off in its decomposition.

Calcium carbide may be stored in quantities not exceeding five pounds without a licence, providing it is kept in air-tight metal boxes, holding not more than one pound. If more than five pounds is required to be kept, a licence must be obtained, price 5s., which must be renewed annually. These restrictions, combined with those of the fire insurance companies, are all against the progress of acetylene as an illuminant, much less for motive power, for which it is also applicable; but, no doubt, as it is better understood some at least, of the restrictions will probably be relaxed.

C. T. SUTTON.

## WEAR AND TEAR IN LIMELIGHT APPARATUS.

DURING what may be termed the off season is the time when lanterns and limelight apparatus are generally stored away, and but little thought bestowed upon their condition, a state of matters that very probably is, with a large number of lanternists, allowed to continue till the autumn begins to set in, when they suddenly waken up with renewed interest at the approach of another lantern season, only to find their lantern and all its belongings in a sorry condition, from sheer neglect and carelessness for months past.

But few lanterns or parts of a limelight outfit will do a fairly heavy season's work without showing signs of wear and tear, and the renovation of them is, without doubt, best accomplished with as little delay as possible. Every one knows how insidiously rust will appear and make its presence felt even on the face of things. There is, however, a far more hidden source where rust, if allowed to remain, will certainly cause deterioration in one of the most vital parts of a lantern outfit, and it therefore is time well spent when any one who takes interest in lantern projection devotes a portion of an evening to a thorough overhaul of his apparatus before storing it away till another season.

Among the various parts of a lantern outfit most liable to suffer from wear and tear is the jet. Somewhat recently a jet was handed to me by a gentleman, who was loud in his praises of this particular pattern, with the request that I should give an opinion as to what had gone wrong with it, for towards the close of the season nothing like previous results could be derived with it, and, as he said, it was running away with nearly double the amount of gas it burned at first without yielding anything like the light. The jet in question was of the very best workmanship, being made by one of the leading English makers, and was in every sense a really good article, and when in proper condition was capable of yielding an honest 900 or 1000 candle-power light without any undue noise; but, in the condition into which it had been allowed to drift by reason of sheer negligence, it was impossible to get anything like such results, for the moment a fair amount of pressure was admitted to the mixing chamber on went the hiss at once.

On taking the jet to pieces and examining the mixing chamber, it was at once apparent what was wrong. By careless manipulation some rather violent snapping of the jet had been allowed to take place, and this had actually ruptured the packing of the jet to such an extent as to literally blow holes, that formed apertures of at least an eighth of an inch, right through the copper gauze, forming small cones through each disc from the bottom to the top of the chamber. The damage was so great as to completely destroy the packing, upon which so much depended for a silent light in the particular pattern of jet referred to. It was, therefore, no wonder that the jet could not be made to work with the usual pressure, or give its best results in the way of light.

For a time it was thought that all that was wanting to bring the jet into its original condition was a supply of new packing formed of alternate rings and discs and pieces of gauze that entirely filled the mixing chamber, and these were provided; but, even when they were placed into the chamber, and any one naturally would have deemed the jet as good as new, something was still wrong that for a time gave a fair amount of trouble to find out. The jet, after being packed and tried on the screen, seemed to run away with more gas than it should, when the aperture of the nipple was taken into consideration, and there was just a semblance of unsteadiness in the light that ought not to be present in a perfect jet. For a time this unsteadiness was attributed to jerking of the springs of the regulators, but, on trying others, the same fault was still present. Then the rubber tubes were tested for punctures; but no, for by this time I had formed an opinion that there was a leakage of gas somewhere; but, having so recently overhauled the jet, I never for a moment dreamt of looking for a leakage in the mixing chamber. After several tests, I was at last driven to the conclusion that the jet was still faulty, and then arrangements were made by utilising two of Clarkson's original rubber regulators, which were perfectly tight. To test the soundness of the jet, the rubber tubes were attached to the regulator, and by their means they were inflated to their full extent. The tubes were then attached to the jets, and the orifice of the nipple plugged, when the jet taps were turned full on. No sooner had this test been applied than the flaw was discovered, a very heavy leakage of gas was found to be coming from under the screw covering cap of the mixing chamber, a leakage permitting a quantity of gas quite as great as was passing out of the nipple when the full pressure was applied to the jet. A slight inspection showed that the washer that was fitted under the base plate of the nipple had been practically destroyed by the heat or the snapping of the jet, or the wear and tear, and was not causing a tight junction between the chamber and the nipple plate. A disc—or, rather, a washer—of thin asbestos card was cut and fitted to the top of the chamber, and this at once cured the jet, which gave magnificent results straightway.

But few people have any idea of the care necessary in working a really first-class jet, and I have known one of the best modern patterns of jets almost ruined by being hired out into the hands of a novice who really did not know how to work such. Much of the success of a jet and its working lies in a proper knowledge of the distance at which to place the nipple from the lime, and with novices it is just here where so many get astray. Some I have met with seem to have an idea that a mixing

jet should be brought as close to a lime without touching as possible, and very probably that belief has been engendered by reading some old treatise on the lime light that was written before the advent of compressed gas in cylinders. At any rate, the practice of bringing a powerful jet too close up to the lime is soon disastrous to the nipple, and, when this part of a jet gives out in the middle of an entertainment, it is a bad job indeed. Yet I am told by opticians that the burning of nipples by careless adjustment of the distance of the lime from the nipple is a very common occurrence. Therefore, at the close of a season, the nipples of all jets, even where they have been carefully manipulated, are almost certain to show symptoms of wear and tear, and, when this is seen to be of any importance, fresh nipples ought to be screwed on. Any maker of jets will supply new nipples, and, when purchasing a jet, it is well to lay in a few spare ones as a stand-by against such eventualities. Many an otherwise perfect jet is practically discarded and thrown aside as done by reason of hissing from a faulty nipple, and an entirely new jet provided at a considerable cost, when all that is really needed is the provision of a new nipple at the cost of a shilling or so.

With large-bore jets platinum-tipped nipples are liable to give way unless the platinum is carried a long way down the nipple. Smaller apertures, however, when the jet is well taken care of, may be made to last for a considerable time. Nipples made of hard brass are quite as serviceable, much cheaper, and a few of them can be kept on hand and made to replace one that has given out quite as easily as the screwing of a nipple into an ordinary gas pipe.

Regulators do not last for ever either, and at the close of a season these should be subjected to a thorough overhaul, and made to cut off the gas entirely when the pressure from the cylinders is partially applied. Some of the good old patterns are still found doing useful service where they have been carefully preserved, and not a few clever operators in the West of Scotland are still to be found who admire the rubber-bellows form, simply because they can see when they are having their supply of gas all right from the cylinders, and so know just when to turn on a little more pressure from the main supply. These old forms of rubber regulators, although they possess some very good points, do, on the other hand, give uneasiness by reason of their leaking from wear and tear, but they are easily overhauled and made perfectly tight by using a small portion of a broad indiarubber band, or piece of very thin rubber sheeting, and a little indiarubber solution. There is, however, a proper way of applying the latter to the rubber bag as a patch; the solution should first of all be applied to both, and allowed to set until it has become almost hardened, the two surfaces are then brought into close contact and pressure applied, after which there will be no leakage. There is also another very simple method of stopping a leak in an indiarubber gas-holder, and one which for years was used when gas bags were in general use, it is merely taking a piece of ordinary sticking plaster and applying the same as a patch to the faulty part, and this does most efficient service at a pinch. With nearly every pattern of regulator there is some weak spot in its construction; if it is not one thing, it is another; the main object, however, should be to make a point that, whichever pattern is used, every care be taken to see that it is in perfect condition. Some operators declare that at times they are prone to yield a jerky light by reason of their springs not working smoothly; this all shows the need for regularly overhauling them during the off season.

The optical parts of a lantern seldom give much trouble when they have been well taken care of. Carelessness, however, sometimes causes damage to the front lens of a condenser by forcing a carrier across its face when the lens is too far forward in its jacket; the result of this is sometimes seen in nasty scratches right in the centre of the front lens, and these scratches, of course, show up as dark patches on the screen, especially where long-focus objectives are employed. If these scratches are not very pronounced, they may be rubbed down by the exercise of a large amount of patience with the aid of elbow grease, a pad of silk, and a little rouge powder. Any damage to the front lens of a condenser is always badly seen on the screen, and, if these are merely superficial, they may be rubbed down as stated; but the operation is one entailing a lot of continuous hard rubbing for several hours from day to day. More serious flaws are only to be dealt with by the practical lens-grinder. A good condenser is well worthy of care, and I often think this is the most essential part of a lantern outfit.

Rubber tubing, after being in use, is liable to contract damage; in fact, it is seldom above suspicion of having deteriorated at any time. It is therefore advisable to test it by plugging one end, and inserting the tubes in a pail of water, and then inflating them; if there be any leakage, this treatment will soon display the weak part.

Dissolvers generally take some time to get into good working order, and frequently have to be doctored. These will require overhauling also, but, where they have not suffered damage in packing or by other rough usage, they can generally be kept in good condition by cleaning the passage ways and screwing the parts up tight.

Where a wooden box or cabinet is employed for packing a limelight outfit, it will hardly ever be found to do service for a season without showing wear and tear. In single lantern outfits it looks as if boxes or iron cases are soon to be discarded for the purposes of packing. I know of one very superior single-lantern outfit in which the entire apparatus, including a twelve-foot linen sheet, is all packed, with the exception of

the jet and lenses, in a stout rubber-cloth hold-all, and I can testify to the practicability of employing it. The lantern in question is practically capable of being taken to pieces, i.e., there are no telescopic fronts to take up room, the objectives are placed on uprights at the end of a travelling platform. This platform and its upright is easily taken to pieces also, and it is quite surprising into what a small bulk the whole apparatus can be packed; in fact, the whole baggage, when the lenses and jets are carried separately in the pocket, takes up no more room than a half-plate outfit, and no one would ever dream of such being a lantern with its accessories.

It would appear as if open stages will be more employed in first-class lanterns in the future. There certainly is no need for the elaborate telescopic fronts hitherto seen in all our lanterns. Any one who has experience of working an open-stage lantern will readily admit the advantages it possesses, not the least being the saving in bulk, for all the parts can be folded up flat, taking hardly any space in packing. A really well-made jet should have a case to itself, and after being used should be carefully placed in the same, and such small cases are capable of being carried in a top-coat pocket apart from the lantern outfit entirely.

We hear a great deal from time to time about elaborate attachments to lantern cabinets for the purpose of tilting the lamp to any desired elevation. I have always striven to do with the least possible amount of accessories, and never could see why some writers should devote whole pages of our photographic journals in which elaborate diagrams are displayed over such a trivial matter. My earliest connexion with the lantern, now very many years ago, effectually solved the problem of elevating the front of lanterns in so simple a manner that I often feel surprised writers should ever think of spending so much time and thought over such a trifle. The best tilting arrangement any one can possibly use consists of the back of a printing frame. This simple contrivance folds up into little or no space, and can be made to yield any elevation by the exercise of several different methods of using it, which any intelligent lanternist can find out for himself.

A. T. NEWTON.

#### NEWS AND NOTES.

THE flame of acetylene is exceedingly useful for hard soldering, says *Neueste Erfindungen und Erfahrungen*. Its temperature is as high as can otherwise be obtained only with a special blowing apparatus. The heating power of acetylene is likewise very great. The use of acetylene is particularly in place where no connexion with a gas house or electric central station can be had.

IN order to prevent the danger of an explosion in acetylene burners, it has been proposed to lead the gas on its way to the end of the burner through a few small chambers filled with glass wool (spun glass). Owing to the fact that spun glass acts like a filter, the acetylene is, before burning, freed from all impurities which might have been carried along. Besides, these spun-wool filters also serve the purpose of preventing a falling back of the flame and rendering it harmless even in case an explosion should occur through some cause or other.—*Neueste Erfindungen und Erfahrungen*.

A NEW method of illumination on the ocean consists of using a hollow cylinder of steel tubing charged with calcium carbide. This shell is to be shot from a gun to a distance of two miles. When it strikes the water it generates acetylene gas and gives 1000 candle power, which burns from the end which floats. This light cannot be extinguished by water.

TRIBOLUMINESCENCE is a name lately given to the emission of light without heat that occurs on crushing certain substances like sugar. The phenomenon has been found by Mr. William J. Pope to be particularly striking in saccharine under certain conditions, the bluish-white flash when the crystals are broken in any way being noticeable in a well-lighted room; but no light appears when the saccharine is pure, or when the crystals are prepared in any way except by evaporating a solution in acetone, or after the crystals have stood a few weeks. Other substances showing the strange phosphorescence are hippuric acid and certain derivatives of santonin. The cause is still a mystery, but recent study seems to indicate that the light is due to some peculiarity of crystalline structure.

A SINGULAR discovery reported by M. Mourel to the Paris Academy is that specially prepared sulphides of strontium, calcium, barium, and zinc are made much more brilliantly phosphorescent by exposure to diffused daylight than to direct sunlight, and that periodical exposure to diffused daylight remarkably increases the phosphorescent power. A portion of the material brought to the sensitive state may excite phosphorescence in another portion, even in a separate glass tube.

THE *Westminster Gazette* has received from a correspondent who has been looking into the matter at the Patent Office a communication with reference to the remarks it has made from time to time as to the approaching expiration of important Welsbach patents. He observes that no patents which may have been acquired before 1885 are of interest in the present circumstances, for the fourteen years' protection has expired. On the other hand, recent patents since, say, 1890, have another six years or more to run. But there are important patents dated about 1885 and 1886, leading patents, associated with the name of Welsbach, and protected incandescent mantles and burners. The first of these, and the one to which most importance may be attached, is 15,286 of December 12, 1885—a leading patent for several others. This protects the method of preparing the incandescent caps or hoods by saturating them with a solution of rare metallic salts. This patent will expire before the end of the present year. The next in time, and one also very important, is of date March 13, 1886. It also covers a method of preparing mantles, and terminates next year. A third patent in July of the same year (1886) protects atmospheric gas burners specially designed for use with the mantles described in the 1885 patent. This runs out about the middle of 1900.

THE Berlin correspondent of the *Daily Chronicle* says that some remarkable experiments with the cinematograph in the service of medicine have just been made in Kiel before a select company assembled in the University. There were present the Prince of Monaco, Professor Von Esmarch, the famous surgeon, and numerous doctors, professors, and medical students. The celebrated French surgeon, M. Doyen, who had charge of the experiments, explained that no work on surgical practice was able to describe operations so carefully and fully as to avoid the possibility of erroneous treatment by the operator. M. Doyen, by means of certain alterations in the cinematograph, has been enabled to take a perfect series of pictures of various kinds of operations, from the first cut of the knife to the laying on of bandages. Every phase of the operations was thrown on the screen with marvellous accuracy. M. Doyen insists that his invention will be of incalculable benefit to students of surgery. The French doctor received an ovation from the medical students assembled to witness the experiments.

#### KINEMATOGRAPH EFFECTS.

APART from its utility as a newagent there seems to be quite a number of less ambitious, but not less profitable, uses to which the cinematograph is likely in the coming season to be applied. Having successfully mirrored nature in motion, the machine is to be utilised to display certain manufactured effects which when duly projected exhibit beautiful and astonishing phenomena, in which colour and various ingenious surprises are included. Prominent amongst workers in this direction is Mr. J. Williamson, of Hove, who recently showed us a number of his forthcoming novelties which vastly interested us. It would at this date hardly be fair to publish particulars of the above, enough that they include several sensational developments which will not only be greatly appreciated at evening entertainments, but should become valuable media for advertising purposes.

#### SOME GERMAN ACETYLENE STATISTICS.

Two of the German acetylene journals have become interested in the statistical side of that industry, and have collected and published considerable data upon the subject. One of these journals, *Das Acetylen* some time ago, sent out fifty-two blanks and received thirty-seven answers, from which, with collateral information, the following figures were derived.

In 1898 in the German acetylene apparatus shops there were sold—

Generators .....	6,451
Burner capacity of each generator .....	1 to 300
Total burner capacity .....	112,355
Candle power of burners in Hefner candles .....	10 to 60
Candle power of burners in Hefner candles, total .....	3,182,100
Average burner capacity of generator .....	17
Average candle power of burner in Hefner candles .....	28

The demand was greatest for apparatus having a capacity of fifteen to thirty burners.

Upon the basis that the generation of one Hefner candle (0.888 English candle, requires 0.0265 cubic feet of acetylene, the above capacity of 3,182,100 candles would require the consumption of 84,325 cubic feet of acetylene. If one pound of carbide generates 4.8 cubic feet of gas, there was therefore required a supply of 17,567 pounds of carbide per hour, or, on a basis of a yield of 4.46 cubic feet per pound, an hourly consumption of 19,000 pounds of carbide. Counting 1900 burning hours per year, the yearly demand for carbide was respectively 16,688 and 18,050 short tons. Taking the price of carbide at 4 cents per lb. or \$80

per ton, we see that the sales must have aggregated, for 16,688 tons consumption, about \$1,335,040. This sum doubles itself when we consider that but about half the German and Swiss production of carbide is used in these countries, and therefore that at least \$2,770,000 worth of carbide was turned out during 1898.

Generators having a capacity of twenty-five burners are most in demand, and most of this size are sold. The average price being \$125, and 6451 of these being sold would bring the total up to \$806,375. Calculating that one burner costs 25 cents, the 112,355 burners going with these generators will cost \$28,089. The carbide works and acetylene apparatus manufacturers in Germany, therefore, did a business in 1898 amounting to \$8,604,464.

The nine largest acetylene firms in Germany have a capital of \$1,122,500, and the small firms, having a capital under \$25,000 each, will aggregate \$153,750, making a grand total of \$1,276,250. There are 1020 men employed in the shops.

The practice seems to be to make the distribution pipes not so strong as ordinary city gas pipes above 1.5 inches diameter, and to have them with but one-third the cross-sectional area for the same service. The valves and fixtures are made of brass, rod castings (75 to 80 per cent. copper), white metal, and iron. Practice has shown that the fear formerly existing as to the formation of explosive acetylides of copper has no foundation.

For generator construction, with few exceptions, leaded iron is used, the plates being from 0.63 to 0.016 inch in thickness (Nos. 10 to 12); in one case, a pressure generator, the walls were from 0.23 to 0.58 inch thick. One firm reported the following weight of plate used: 15-flame generators, 0.039 inch; 30-flame, 0.058 inch; 100-flame, 0.078 inch; 150-flame, 0.117 inch; above this, 0.156 to 0.175 inch. Another firm does not go below 0.058 inch plates even for three to six-flame generators. All firms offer the forked burner, some entirely of steatite, and others with steatite heads only, and either angular or of horseshoe shape. In answer to the query as to how many feet of pipe had been laid, seven firms answered that they had put in 533,000 feet of from  $\frac{1}{4}$  to 3-inch pipe.

#### STEREOSCOPIC PHOTOGRAPHS: A NEW METHOD OF TAKING AND EXHIBITING THEM.

THIS is due to Mr. W. K. L. Dickson, and it "consists in the provision of means for varying the angle of divergence between the axes of the pencils of light by which the twin stereoscopic pictures are produced, or transmitted to the eye, without varying the distance between the twin images on the photographic plate or on the stereoscopic picture card, and for bringing the centres of the images on the photographic plate much closer together than the distance between the axes of the pencils of light by which said images are produced, and for obviating the necessity of cutting apart, transposing, and reconnecting the twin pictures of photographic prints made from a stereoscopic negative, in order to prepare the same for exhibition; in the provision of means for varying the distance between the twin lenses; and, generally, in the novel combination, construction, and arrangement of the parts."

Mr. Dickson proceeds:—

"In the taking of stereoscopic photographs it is sometimes desirable to vary the angle of divergence between the axes of the pencils of light by which the twin images are produced, so as to exaggerate or diminish the effect of perspective produced. In the taking of consecutive series of stereoscopic pictures of moving objects, such as are to be employed in the reproduction to the eye of the movements of such objects in what are known as consecutive-view or moving-picture apparatus, it is very desirable to bring the twin images much closer together upon the photographic plate or film than the distance between the axes of the pencils of light by which these images are produced. The photographs usually employed in consecutive-view apparatus are comparatively small, and, if the distance between the centres of the twin images produced by a stereoscopic consecutive-view camera be the same as the distance between the centres of the lenses of an ordinary stereoscopic camera, there is a great waste of film; and the inertia of the excessively wide strip of film seriously interferes with the taking of pictures in such rapid succession as is desirable for the production of the desired effects. Furthermore, in the making of stereoscopic pictures from ordinary stereoscopic negatives, it is necessary to cut apart the twin pictures of the photographic print, transpose them, and reconnect them, or mount them side by side on a common support. It is impracticable to do this with the large number of prints required for a single set of pictures of a consecutive-view exhibiting apparatus.

"The objects of my invention are, first, to provide means for varying, in stereoscopic cameras, or exhibiting apparatus, the degree of perspective effect produced, and for bringing the images much closer together than is ordinarily the case in stereoscopic negatives or pictures, such images, however, being, in fact, substantially the same as though observed from points more widely separated than the actual distance between their centres; second, to provide means for obviating the necessity of transposing the twin pictures of stereoscopic photographic prints; and,

third, to make the apparatus simple, durable, efficient, and as inexpensive as possible.

"Fig. 1 is a plan view of the lens mountings, prisms, and connected parts of a stereoscopic photographic apparatus embodying my invention, detached from the camera, a portion of the front board only of which is shown in section; fig. 2 is a side view of the parts shown in fig. 1, taken from the right of fig. 1; fig. 3 is a front view of the parts shown in fig. 1, said parts having been inverted; and fig. 4 is a diagram illustrating the action of the apparatus.

"In the drawings, 1 and 1<sup>1</sup> are the lens tubes of two twin photographic lenses. They are telescopic, and racks, 2 and 2<sup>1</sup>, a pinion shaft, 3, having a thumb screw, 3<sup>1</sup>, and pinions, 4 and 4<sup>1</sup>, are provided, for the purpose of focussing the lenses. In front of the lens tubes are mounted reflecting prisms, 5 and 5<sup>1</sup>. The prism, 5<sup>1</sup>, may be secured directly to its

lens tube, while the prism, 5, may be mounted upon guide rods, 6, in such manner that it may be moved toward or from its lens tube upon said rods. The length of the guide rods is such that the distance between the reflected extensions of the optical axes of the lenses may be at least as great as the distance between the axes of the lenses of an ordinary stereoscopic camera.

"In fig. 1, and also in fig. 4, the lines, 7 and 7<sup>1</sup>, represent the axes of the lenses, the distance,  $x$ , being the distance between them. The lines, 8 and 8<sup>1</sup>, represent reflected extensions of these axes, and proceed from the central point of the reflecting surfaces of the prisms, 5 and 5<sup>1</sup>. The lines, 8 and 8<sup>1</sup>, may be termed reflected optical axes. The distance,  $y$ , is the distance between the lines, 8 and 8<sup>1</sup>. It is apparent that the distance,  $y$ , may be varied by moving the prism, 5, in or out on its guides, 6, without altering the distance,  $x$ . The images projected upon the sensitive plate within the camera are substantially the same as the images which would be observed from points on rearward extensions of the lines, 8 and 8<sup>1</sup>, and differ from each other to the same extent that the images which might be seen from rearward extensions of the lines, 8 and 8<sup>1</sup>, if the prisms were removed, would differ. By moving the prism, 5, in or out, therefore, the angle of divergence between the pencils of light by which the different images reflected on to the sensitive plate within the camera are produced may be varied; and, by varying this angle of divergence, the degree of the perspective effect produced is varied. The distance,  $y$ , when measured close to the prism, is the measure of this angle of divergence, and also serves, by comparison with the distance,  $x$ , to show the degree of concentration of the images upon the negative plate which results from the use of the prisms. From fig. 4 it is evident that the images on the negative are very much closer together than would be the case if an ordinary stereoscopic camera, the axes of the lenses of which are as far apart as the lines, 8 and 8<sup>1</sup>, were used, while the effect of perspective obtained is the same as would be obtained by the use of an ordinary stereoscopic camera with the axes of its lenses as far separated as are the lines, 8 and 8<sup>1</sup>. The reflection of the pencils of light by which the twin images are produced necessarily results in a crossing of the rays of each of said pencils, and therefore results in the reversal, in the negative, of the relations of right and left of the image from those relations which would exist in a negative made by an ordinary camera. This, however, is an advantage, for prints made from stereoscopic negatives produced in an ordinary stereoscopic camera must be cut apart, so that the twin pictures may be transposed and then reunited by mounting upon a common backing. This is well known. The negatives made in a stereoscopic camera constructed in accordance with my invention are printed from with the emulsion side of the negative turned away from the sensitive side of the positive. Were an ordinary stereoscopic negative printed from in this manner, the right

and left of each image would be transposed with respect to the right and left of the object photographed; but, by reason of the reversal which takes place in the reflecting prisms, prints made in the manner described from negatives produced in my camera have the correct relation of right and left in each image as well as the correct relation of the two images. Projection printing is, however, preferable.

"It is sometimes desirable to adjust the distance between the lenses, as the size of image produced sometimes varies, and for this reason the lens tubes are mounted in separate slides, 9 and 9<sup>1</sup>, mounted in grooves in a plate, 10, itself arranged to slide in a direction at right angles to the direction of motion of the slides, 9 and 9<sup>1</sup>, in grooves in a base plate, 11, adapted to be secured to the front board of the camera.

"While this invention has been shown as applied to a photographic camera, it may equally be applied to a stereoscopic exhibiting apparatus, if desired, though ordinarily this will not be necessary. Instead of employing reflecting prisms, as shown, mirrors may be used, the mirrors being equivalents of prisms."

### A NEW FORM OF STEREOPTICON.

A MULTIPLE dissolving-view lantern has been invented by Dr. Samuel E. Woody, 600, West Broadway, Louisville, Ky., which includes various improvements in construction, by which the light is so refracted that the picture from each of the two optical systems appears on the same spot of the screen. It is described in the *Scientific American*.

Referring to fig. 2 of the engraving, it will be observed that two condensers are mounted at the end of the light-casing, the upper being fitted to slide in a segmental guideway on the light-casing so that it can be adjusted relatively to the lower, by means of a wedge interposed between the frames of the condensers. By reason of this adjustment a proper registration of the two pictures projected by the two optical systems is obtained.

Each condenser is provided with two plano-convex lenses, having a prism interposed between them so that the rays of light passing to the first lens are refracted by the prism to the other lens adjacent to the

2.  
A New Form of Stereopticon.

slide-holder. The two lenses of each condenser are inclined to each other, and the interposed prism refracts the rays of light at a proper angle.

The apparatus is provided with a shutter held movably in the light-casing between the light and the condensers. By operating the shutter the rays can be made to pass through one or the other of the condensers.

In the modified form shown in fig. 1, the light-casing, in addition to the ordinary function, serves as a receptacle for the condensers, the slide-holders, and the adjustable tubes carrying the objectives, thus facilitating the transportation of the apparatus. In order to obtain this compact arrangement, the bottom of the light-casing is formed with a dovetail groove adapted to register with a similar groove in an extension hinged to the outer end of the bottom, and forming a cover for the open end of the casing when the several parts are stored. In the registering dovetail grooves a support slides which carries the stereopticon parts. In using the device the extension is swung down and the support carrying the stereopticon is slid out, reversed, and reinserted in its proper operative position.

### THE HYGIENE OF ACETYLENE.

It is strange that, while acetylene is already so largely used and while much has been written concerning its composition, its mode of production, and the burners best adapted for its combustion, little is known with respect to its influence upon health. The facts connected with this can conveniently be discussed under three heads: (1) The action of acetylene gas when mingled with the atmosphere; (2) the action of the products of combustion of acetylene; and (3) to impurities in acetylene. It may be pointed out that, in consequence of the fact that calcium carbide is hygroscopic, this substance is liable to cause the spontaneous evolution of gas by gradually attracting moisture from the atmosphere. An American physician, Dr. Birchmoore, has maintained that even a volume of 0.01 per cent. of this gas in the atmosphere produces headache and sickness. Trouvé has asserted that this gas relieves colds and coughs. According to Gréban, even 20 per cent. of this gas in the atmosphere produces no evil effects when breathed by animals, but with 40 per cent. the mixture was speedily fatal.

Under the second head, after a full consideration of the gases caused by burning pure acetylene, and after comparing them with those obtained by the combustion of common coal gas, it may be affirmed that acetylene under similar conditions, that is to say, with the production of an equal amount of light, vitiates less than one-half the volume of air that coal gas does, and gives rise to far fewer products of combustion. There are certain impurities likely to be present in acetylene, caused by certain substances found in the raw materials used in making the calcium carbide, and they consist mainly of phosphorus, sulphur, silicon, and nitrogen compounds. It is impossible for these substances, except perhaps phosphorus, with common care in the manufacture, to exist in sufficient quantities to cause any ill effects to health.

### FLASHLIGHT PHOTOGRAPHY—BOYER'S SYSTEM.

M. BOTER gives the following description in his Patent specification of the apparatus he has devised for the above purpose:—

"I provide two series of hinged covered frames or their equivalents formed at their sides to fit closely together so as to constitute a compound screen or the inner and outer walls and ceiling of a cabinet or studio, an intervening space being left between the two series. One series of frames forming the outer wall is covered with opaque material, and is preferably provided inwardly with material forming reflecting surfaces, the other series of frames forming the inner wall being covered with a translucent material with a matt or dull surface, so that rays of light passing there-through are diffused. The magnesium or the like flashlights are

arranged on carriers in the space between the two series of covered frames, and are preferably automatic in action, so that a number of such flashlights can be ignited in quick succession. An adjusting device for regulating the angle between the parts of the frame forming the wall and the parts forming the ceiling is preferably employed, together with a fan or other exhausting device which may be worked by an electric motor

for removing the fumes produced between the inner and outer walls by the burning of the magnesium or the like.

"Fig. 1 illustrates in perspective an arrangement of frames and accessories forming a compound screen or a wall and ceiling, it being readily understood that I may use any number of such frames which may be fitted together so as to constitute an entire cabinet, room or studio.

"Fig. 2 shows in perspective a single compound screen, which may be used complete in itself, for illuminating the subject to be photographed.

"In fig. 1,  $\Delta\Delta^1\Delta^2$  indicate the inner series of divided frames or screens, hinged at  $a$  so that the two parts of each frame or screen can be folded together to facilitate packing.  $\Delta\Delta^1\Delta^2$  indicate the outer series, which are hinged at  $b$ . Each frame or screen is formed with its sides alternately tongued and grooved so as to fit closely together when placed in position,  $c$  being a base with grooves,  $c$ , into which the said screens,  $\Delta$  and  $\Delta^1$ , are slid.  $d$  are telescopic arms for adjusting the angle of the upper part

of the frames relatively to the lower part. The outer and inner frames or screens are connected together at their upper parts by braces or tie rods,  $d$ . The magnesium or the like lights are inserted between the screens as indicated by the dotted lines at  $e$ , and  $f$  is a fan driven by an electric motor for exhausting the fumes arising from the burning of the magnesium or the like, and conducting them outside by the pipe,  $f$ , which may open into the chimney of the room in which the apparatus is erected on lead to an open window.  $x$  indicates the electric conductors for driving the motor. The inner surfaces of the screens,  $\Delta\Delta^1\Delta^2$ , are made of a translucent material with a matt or dull surface and the surfaces of the screens,  $\Delta\Delta^1\Delta^2$ , are made opaque outwardly, and preferably with shining or reflecting surfaces inwardly.

"In fig. 2 the compound screen,  $\Delta B$ , is arranged to be used separately, and in this case without a fan; the pipe,  $f$ , for exhausting the fumes, may be placed at the top of the apparatus, from which a pipe may be taken to the window or chimney.  $g$  are supports for holding the screen upright, the sides and top end,  $h$ , are shown closed in, to prevent the escape of the fumes into the studio, the other parts of the apparatus being similar to those already described with reference to fig. 1.

"When a portrait is to be taken, the studio or screen is set up and the light or lights arranged in any desired number and positions in the intervening space is or are ignited by any suitable means; the chamber or studio or screen will then be found to be flooded with a diffused light, shed through the inner translucent walls and reflected back from the inner surfaces of the outer walls without causing a glare to the person being photographed, however brilliant and numerous the lights in the intermediate space between the two walls of the studio or screen may be."

Electricity, which is published in New York, describes an electric double-ray head light for use on locomotives, which, if found to fulfil its early promise, should be of great service on our railway systems. A plane reflector is attached to the head-light case at an angle of  $45^\circ$  in such a manner that one-third of the total candle power of the head light is projected vertically in the air to a distance of 1000 or 2000 feet, making a beam of light which can be seen from any point from within a radius of from five to ten miles, according to the condition of the weather, and thus one can approximately locate the position of a locomotive approaching from any direction.

### LANTERN MEMS.

WITH one of the hottest Julys that have been experienced for many years past, and a near approach to, if not an actual record, of continuous sunshine, one may be excused for directing thoughts to other subjects than lantern matters, especially when one's professional duties cause one to "dwell in tents" for the whole of the month. To see the unbroken curves of the registered sunshine on the chart of Jordan's photographic sunshine recorder, representing a record of nearly fourteen hours continuous sunshine, is sufficient evidence of the energy of King Sol, and when one looks at the solar radiation thermometer, and finds it shows 146° F. in the sun, an excuse is easily found for not entering into other matters than business or private reasons necessitate.

My annual outing at Bisley Camp and in Ireland is now over, and I am once more back to the comforts of civilised life, but whether the dwellers in houses are better off than those who have only canvas to cover them at night is a problem I will not attempt to solve; all I know is that under canvas, at a temperature of 90° F. with the air, or what can be obtained of it, blowing through the tent, is trying enough, while most houses have a shady side, and, if one can pick and choose positions for working, the balance should be on the side of bricks and mortar. If the seasons were consistent, and we were sure of such summer weather as that experienced last month, then a "siesta" would have to be an established matter for business men as well as those who can control their movements in order that work may be performed in reasonable comfort.

Now to optical matters. Everything in turn seems being recorded by photography, and the list of scientific and other work accomplished by cinematograph and kindred cameras would be too long for insertion here. I have, however, recently been associated with the construction of a camera for recording flashes of light, as performed by the movements of a silver mirror attached to a key that can be worked as a tapper, and permits of the duration of the flash being short or long, so as to send signals by the Morse code, such as is done by the heliograph. The new apparatus, which has given successful results, and is appreciated by the gentleman who gave the order for same, and enumerated the conditions to be fulfilled, is fitted with a narrow sensitive film, which passes from

one light-tight box, through the camera, into another light-tight box, and during the passage receives the impressions of the heliograph flashed from a moderate distance.

The clockwork and other arrangements for controlling the film have been very ingeniously devised and carried out by the mechanic who was intrusted with the work, and the perfect manner in which the rate of movement of film can be varied leaves nothing to be desired, while the stopping of the film is certain, and any portion of the exposed film can be removed and developed as desired, and another light-tight receptacle put in place of the one removed to hold further exposures. The record of long or short flashes was shown by broad or narrow bands, made by the light passing through a narrow slit in a metal plate, immediately in front of the film, the breadth of the record depending on the rate of the movement of the clockwork and duration of flashes. The details as to finders, adjustments, and stand were matters that had to be considered for convenience of working, but were of the ordinary commercial patterns. What, however, was accomplished was a complete control of the movement of the film by a very sensitive regulator to the clockwork that enabled the film to be passed through at any speed desired, to suit the particular "sending" of the heliograph message which in turn was thus recorded.

I SAW it recently stated that the man who can first invent a practical electrical storage battery of moderate size and weight will, in a short time after its introduction and the demonstration of its utility, be in the possession of one of the largest fortunes ever possessed by an inventor in recent years, and this I believe, although already some colossal incomes and fortunes have been made from apparently simple ideas put into practical shape. Certainly for lanternists a storage battery of fifty-six pounds weight, or thereabout, that will give, say, eighty volts and ten amperes of current for two or three hours, would be a boon; and the inventor thereof, if such a thing is possible, will be a great benefactor to operators, and hold a higher place in their estimation than the introducers of the compressed oxygen-gas system, that enabled them to dispense with the cumbersome gas bags, pressure boards, and weights of fifteen years ago. The distribution of electrical current is proceeding apace, but there are many towns, suburbs, villages, &c., where even gas is not available, much less electricity; so please hurry up, inventors, and give us bottled-up electricity.

G. R. BAKER.

### RECENT EXPERIMENTS WITH THE LIPPMANN COLOUR PROCESS.

[Translated from Dr. J. M. Eder's *Jahrbuch für Photographie*, 1899.]

THE experiments with Lippmann's Colour Process which the writer commenced in 1894 were continued during the summer of last year, and the following is a short account of the results.

The experiments of the previous year were repeated and fully confirmed.

An abbreviated account of the same was published in the *Jahrbuch* for 1898, and a full description given in a special work upon the subject.\*

In the preparation of gelatine emulsion plates, it was again found that Lautenschlager's gelatine gave the best, or, more correctly speaking, the only usable results. In a series of comparative experiments it was found that the weather had the most important influence upon the quality of the emulsion. In hot, dry (east winds), sultry, tempestuous weather it was impossible to make a satisfactory emulsion. The writer finally prepared the emulsion on cool rainy days only, and was then certain of success.

Although in the past the writer was glad to secure one successful picture on an average from twenty-five mixed colour exposures, by following well-tried rules certainty was so far ensured that, for example, fifteen excellent pictures were obtained from nineteen exposures upon a plate of fruit.

In preparing the emulsion the writer further reduced the temperature to 31°C. in summer and 35°C. in autumn. As this was very little above the setting point of the gelatine, it was, of course, necessary to work as rapidly as possible to secure at least two dozen plates from a batch of emulsion. Re-heating the emulsion is very questionable.

It was found useful to warm all the plates which were to be coated by placing them in an empty metal box (washing tank), under which a small flame was kept burning. The box was closed with a wooden lid, through which a thermometer was thrust to register the temperature, and this was kept at 35° to 40° C. In taking the plates from the box they cool a little, and are then about as warm as the emulsion.

With reference to the mercury, it was found that the chemically pure article obtained from Kahlbaum, of Berlin, kept in purer condition than ordinary mercury.

Occasionally intensification with corrosive sublimate and redevelopment with amidol was of great service. The colours were truer and more brilliant; but the improvement was confined to a few plates only. The same was also found in using Farmer's ferricyanide reducer. It also occasionally happened that mixed-colour exposures were of no use until intensified with corrosive sublimate and amidol and reduced with Farmer's reducer. But it is undesirable to rely upon such a complicated process, which also involves great risks to the image. The constant aim should be to obtain the colours as bright and correct as possible by simple development. Reduction should always be done very slowly with very dilute solutions, otherwise the colours are lost beyond recovery. No satisfactory results were obtained with the new persulphate of ammonium reducer.

As a rule, mixed-colour pictures with gelatine emulsion are less brilliant when viewed through the glass, but the opposite was the case with some emulsions prepared in the ordinary way. The colours, through the glass, were more correct than when looked at through the film, especially with full exposure and the use of much bromide of potassium. It is difficult to account for the anomalous behaviour of isolated emulsions.

With albumen plates, the use of cleared albumen (see Neuhaus, *Farbenphotographie*, p. 5) was found of great value. The writer was therefore induced to abandon the preparation of plates with fresh albumen from hens' eggs. The clearing of egg albumen with ammonia varies considerably in point of time. Albumen five to six months old gives the best results. Cleared albumen will keep for years. From the writer's experience it was found that albumen which did not give good results when fresh, and even when the clearing process was not quite complete, gave excellent results six months later.

Whilst plates prepared with albumen from fresh hens' eggs always become cloudy in the silver bath, the cleared albumen remains perfectly transparent, and the colours are consequently more brilliant. In 1897 the writer found that the film of albumen was liable to blister under alkaline development. The fault was entirely avoided by using plates which had been coated several months. The action of time is very beneficial to the adhesiveness of the film. It is worth noting that albumen plates may be developed without alkali by using a hot solution of pyrogallol, a fact which was brought to our notice by a letter received from Professor G. Lippmann (Paris). This is important where there is a tendency to frilling, because the latter is favoured by the use of alkalies.

To simplify the albumen process, by omitting the colour-sensitising after the silver bath, we tried the addition of the dye to the albumen. Erythrosine is easily soluble in albumen, but cyanine behaves otherwise. If, however, the alcoholic solution of cyanine (1 to 500) is diluted with an equal quantity of water, it may be added drop by drop to cleared

albumen, until the latter is of a deep blue colour, without risk of coagulation. A plain alcoholic solution of cyanine, without the addition of water, would bring about coagulation. But albumen thus sensitised for colour before the silver bath acts differently. Although the action is good in the green, there is insufficient sensitiveness to red, because the cyanine is altered in the acid silver bath.

With reference to the keeping qualities of albumen plates, which have been sensitised in the silver bath and afterwards in the colour bath, a plate which had been so prepared and kept ten months gave an excellent colour picture with very slight tendency to fog. This is of importance from the commercial aspect, if the plates should become a manufactured article.

To dispense with the use of fresh hens' eggs, which are sometimes difficult to get, the writer made experiments with dried albumen. But of all the various sorts only one was found of any use, namely, an American product (albumen *ex ovis crystallis. puriss.*), which was obtained from Simon, chemist, Berlin. This dissolves in water with scarcely any residue. As fresh hens' eggs contain eighty-six per cent. of water, 14 grammes of the dried albumen should be dissolved in 86 grammes of water. But plates thus prepared gave very unsatisfactory colours. Moreover, it is impossible to clear this kind of albumen. The solution goes bad after some time, without having become clear.

Animal albumen cannot be used for emulsions, as it coagulates as soon as it is brought into contact with silver nitrate. It would be advantageous to colour photography if an emulsion process could be worked out with albumen, as this vehicle gives such favourable results, at least with the spectrum. The inconvenience of the silver and the colour-sensitising baths would then be avoided. As the Vienna firm, Lilienfeld & Co., has recently placed albumen papers on the market, which, according to the inventor, are prepared with an emulsion of vegetable albumen, the writer applied to them and inquired if they would place a sample of the emulsion at his disposal to enable him to make some colour experiments. The promise which they very kindly made to send him some, for some unknown reason, has not, however, been kept.

During the past year the writer has again found it impossible to obtain a useful rendering of mixed colours upon albumen plates, notwithstanding the most varied experiments. Their appearance is always such that the correct colours seem to be lower in the film and toned with surface colours. We diligently followed up our experiments of the previous year for the removal of the surface of the film by chemical means (reduction with ferricyanide, &c.), and thus lay bare the colours beneath. But this was attended with complete success in one instance only. This plate was intensified with corrosive sublimate and amidol, and then reduced with ferricyanide and hyposulphite. However, the exception points to the fact that we were on the right road.

Unfortunately, there are too few who have taken up the Lippmann process, although it is the only one which as yet deserves the name of photography in natural colours. Yet the difficulties are much less than they appear. Most of the failures which beginners meet with may be traced to the fact that from want of experience they are not quick enough in preparing the emulsion. This gives it the chance to ripen, and the colour-rendering becomes defective. If beginners would only give themselves the trouble to prepare two or three emulsions, and thus obtain sufficient dexterity of manipulation, they would be rewarded with excellent colours from their subsequent emulsions. Instead of this a few hasty experiments are made with two or three plates, and if these fail the process, of course, is blamed. As in other matters, a little patience and perseverance are necessary to success. Briefly stated, the writer last summer exposed 281 plates, 9 x 12 cm., in the mercury dark slide, although numerous other inquiries prevented him from working at the Lippmann process excepting as a secondary study. One hundred and seventy-five mixed colour and 321 spectrum exposures were made upon these plates; but for the latter one plate was, of course, sufficient for more than one exposure.

In conclusion, we desire to express our warmest thanks to Professor Gabriel Lippmann, of Paris, the genial inventor of the colour process bearing his name, for the great encouragement he has given us during the past summer.

Dr. R. NEUHAUS.

#### THE WAVE THEORY OF LIGHT: ITS INFLUENCE ON MODERN PHYSICS.

[Abstract of Rede Lecture: Reprinted from *Nature*.]

OPTICS are really a modern science. The ancient philosophers had no idea of the complexity of what is vulgarly called light; they confounded in the same name what is proper to man and what is exterior. They had, however, perceived one of the characteristic properties of the link which exists between the source of light and the eye, which receives the

\* Dr. R. Neuhaus, *Die Farbenphotographie nach Lippmann's Verfahren*. W. Knapp, Halle a/S. On p. 24 there is an unfortunate mistake. In the formula for the emulsion, Solution III. should read: bromide of potassium 1.25 grammes; instead of 1.5 grammes.

impression, "Light moves in a straight line." Common experience had revealed this axiom through the observation of the shining trains that the sun throws across the skies, piercing misty clouds, or penetrating into some dark space. Hence arises two empirical notions—the definition of the ray of light, and that of the straight line. The one became the basis of optics, the other that of geometry.

Very little remains to us of the ancient books upon optics. Yet we are aware that they knew the reflection of the luminous rays on polished surfaces, and the geometrical explanation of the images formed by mirrors.

We must wait many centuries until the scientific revival for a new progress in optics (but then a very considerable one) opens the new era; it is the invention of the telescope.

The new era begins with Galileo, Boyle, and Descartes, the founders of experimental philosophy. All devote their life to meditations on light, colours, and forces. Galileo lays the base of mechanics, and with the refracting telescope that of astro-physics. Boyle improves experimentation. As to Descartes, he embraces with his penetrating mind the whole of natural philosophy; he throws away the occult causes admitted by the scholastic, and proclaims as a principle that all phenomena are governed by the laws of mechanics. In his system of the universe, light plays a prominent part; \* it is produced by the waves excited in the subtle matter which, according to his view, pervades space. This subtle matter (which represents what we call to-day the ether) is considered by him as formed of particles in immediate contact; it constitutes thus at the same time the vehicle of the forces existing between the material bodies which are plunged in it. We recognise the famous "vortices of Descartes," sometimes admired, sometimes baffled during the last centuries, but to which skilful contemporaneous physicists have rendered the importance they deserve.

Whatever may be the opinions granted to the exactness of the deductions of this great philosopher, we must be struck by the boldness with which he proclaims the connexion of the great chemical problems, and foretells the solutions which actual generations did not yet entirely accept but drew insensibly to.

In Descartes' view the mechanism of light and that of gravitation are inseparable; the seat of corresponding phenomena is this subtle matter which pervades the universe, and their propagation is performed by waves around the acting centres.

This conception of the nature of light shocked the opinions in vogue; it raised strong opposition. Since the oldest times it was the habit to imagine the luminous ray as the trajectory of rapid projectiles thrown by the radiant source. Their shock on the nerves of the eye produces vision; their resistance or changes of speed, reflection or refraction. The Cartesian theory had, however, some seductive aspects which brought defenders. The waves excited on the surface of still water offer so clear an image of a propagated motion around a disturbing centre! On the other hand, do not the sonorous impressions reach our ear by waves? Our mind feels yet a real satisfaction in thinking that our most sharp and delicate organs are both impressed by a mechanism of the same nature.

Yet a serious difference arose. Sound does not necessarily travel in straight lines as light does. It travels round any object opposed to it, and will follow the most circuitous routes with scarcely any loss of strength. Physicists were thus divided into two camps. In one the partisans of emission, in the other those of the wave theory, each system boasting itself superior, and indeed each being so in certain respects. Other phenomena had to be examined in order to decide between them.

The chance of discovery brought to view several phenomena which ought to have decided in favour of wave theory, as was proved a century later; but the simplest truth does not prevail without long endeavour.

A strange compromise was effected between the two systems, helped on by a name great among the greatest, and for a century the theory of emission triumphed.

The tale is a strange one. In 1661 a young scholar, full of eagerness and penetration, enters Trinity College, Cambridge; his name is Isaac Newton. He has already in his village read Kepler's *Optics*. Almost immediately, and while following Barrow's lectures upon optics, he studies the geometry of Descartes with passionate care; with his savings he buys a prism, that he might examine the properties of colour and meditate deeply on the causes of gravitation. Eight years later his masters think him worthy to succeed Barrow in the Lucasian Professorship, and in his turn he also teaches optics. The pupil soon becomes greater than his teacher, and he gives out this great result: White light which seemed

the type of pure light is not homogeneous; it consists of rays of different refrangibility, and he demonstrates it by the celebrated experiment of the solar spectrum, in which a ray of white light is decomposed into a series of coloured rays like a rainbow; each shade of the colour is simple, for the prism does not decompose the shade. This is the origin of the spectral analysis. This analysis of white light brought Newton to explain the colours of the thin plates which are, for instance, observed in soap bubbles. The fundamental experiment, that of Newton's rings is one of the most instructive in optics, while the laws that govern it are of admirable simplicity.

The theory was expounded in a discourse addressed to the Royal Society with the title, "A New Hypothesis concerning Light and Colour."

This discourse called forth from Hooke a sharp complaint. Hooke also had already examined the colour of thin plates, and endeavoured to explain them in the wave system. He had the merit, which Newton himself readily granted, to substitute for the progressive wave of Descartes a vibrating one—a new and extremely important notion. He had even noticed the part of the two reflecting surfaces of the thin plate, and the mutual action of the reflected waves. Consequently Hooke should have been the very forerunner of the modern theory if he had had, as Newton, the clear intelligence of the simple rays. But his vague reasoning to explain the colours takes away all demonstrative value from his theory.

Newton is very affected by this complaint of priority, and combats the arguments of his adversary by remarking that the wave theory is inadmissible because it does not explain the existence of the luminous ray and of the shadows. He denies the opinion that he has raised a theory; he certifies that he does not admit either the wave hypothesis or the emission, but he says "he shall sometimes, to avoid circumlocution and to represent it conveniently, speak of it as if he assumed it and propounded it to be believed." And really, in the Proposition XL (second book of his *Optics*), which constitutes what was since called the theory of fits, Newton remains absolutely on the ground of facts. He says simply, the phenomena of thin plates prove that the luminous ray is put alternatively in a certain state of fit of easy reflection and of easy transmission. He adds, however, that, if an explanation of these alternative states is required, they can be attributed to the vibrations excited by the shock of the corpuscles, and propagated under the form of a wave in ether.

After all, notwithstanding his desire to remain on the firm ground of facts, Newton cannot help trying a rational explanation. He has too carefully read the writings of Descartes not to be heartily, as Huygens, a partisan of the universal mechanism and not to wish secretly to find in the pure undulations the explanation of the beautiful phenomena he has reduced to such simple laws. But his third book on *Optics* more especially proves his Cartesian aspirations, and, above all, his perplexity. His famous "Queries" expose so forcibly his argument in favour of the wave theory of light that Thos. Young will later cite them as proof of the final conversion of Newton to the wave theory. Newton would certainly have yielded to this secret inclination had the inflexible logic of his mind allowed him to do so; but, when after enumerating the arguments the wave theory of light offers in explanation of the intimate nature of light, when he arrived at the last "queries," he stops, as if seized by a sudden remorse and throws it away. And the sole argument is that he does not see the possibility of explaining the rectilinear transmission of light. Viewed from this standpoint the third book of *Optics* is no longer only an impartial discussion of opposite systems; it appears as the painting of the suffering of a mighty genius, worried by doubt, now led away by the seductive suggestions of his imagination, now recalled by the imperious requirements of logic. It is a drama: the everlasting struggle between love and duty; and duty won.

Such, I take it, is the inner genesis of the theory of fits—a strange mingling of two opposite systems. It was much admired, presented, as it was, by the great mathematician, who had the glory of submitting the motion of all celestial bodies to the one law of universal gravitation.

To-day this theory is abandoned; it is condemned by the *experimentum crucis* of Arago, realised by Fizeau and Foucault. One ought, however, to acknowledge that it has constituted a real progress by the precise and new notions which it contains. The ray of light, considered up till then, was simply the trajectory of a particle in rectilinear motion; the ray of light, such as Newton described it, possesses a regular periodic structure, and the period or interval of fits characterises the colour of the ray. This is an important result. It only requires a more suitable interpretation to transform the luminous ray into a vibratory wave; but we had to wait a century, and Dr. Thomas Young, in 1801, had the honour of discovering it.

\* Le Monde de M. Descartes, ou le Traité de la Lumière (Paris, 1664).

Resuming the study of thin plates, Thomas Young shows that everything is explained with extreme simplicity, if it be supposed that the homogeneous luminous ray is analogous to the sonorous wave produced by a musical sound; that the vibrations of ether ought to compose—that is to say, to interfere—according to the expression that he proposes as to their mutual actions.

Although Young had taken the clever precaution of supporting his views by the authority of Newton,\* the hypothesis found no favour; his principle of interference led to this singular result, that light added to light could, in certain cases produce darkness, a paradoxical result contradicted by daily experience. The only verification that Young brought forward was the existence of dark rings in Newton's experiment, darkness due, according to him, to the interference of waves reflected on the two faces of the plate. But, as the Newtonian theory interpreted the fact in a different manner, the proof remained doubtful; an *experimentum crucis* was wanting. Young did not have the good success to obtain it.

The theory of waves relapsed then once more into the obscurity of controversy, and the terrible argument of the rectilinear propagation was raised afresh against it. The most skilled geometers of the period—Laplace, Biot, Poisson—naturally leaned to the Newtonian opinion; Laplace, in particular, the celebrated author of the *Mécanique Céleste*, had even taken the offensive. He was going to attack the theory of waves in its most strongly fortified intrenchments, which had been raised by the illustrious Huygens.

Huygens, indeed, in his *Traité de la Lumière*, had resolved a problem before which the theory of emission had remained mute; that is to say, the explanation of the double refraction of Iceland spar: the wave theory (on the contrary) reduced to the simplest geometrical construction the path of the two rays, ordinary and extraordinary; experiment confirmed the results in every point. Laplace succeeded in his turn (with the help of hypotheses of the constitution of luminous particles) to explain the path of these strange rays. The victory of the theory of particles then appeared complete; a new phenomenon arrived also appropriately to render it striking.

Malus discovered that a common ray of light, reflected under a certain angle, acquired unsymmetrical properties similar to those rays from a crystal of Iceland spar. He explained this phenomenon by an orientation of the luminous molecule, and, consequently, named this light *polarised light*. This was a new success for emission.

The triumph was not of long duration. In 1816, a young engineer, scarcely out of the École Polytechnique, Augustin Fresnel, confided to Arago his doubts on the theory then in favour, and pointed out to him the experiments which tended to overthrow it.

Supporting himself on the ideas of Huygens, he attacked the formidable question of rays and shadows, and had resolved it; all the phenomena of diffraction were reduced to an analytical problem, and observations verified calculation marvellously. He had, without knowing it, rediscovered Young's reasonings, as well as the principle of interference; but, more fortunate than he, he brought the *experimentum crucis*—the two-mirror experiment; there, two rays, issuing from the same source, free from any disturbance, produced, when they met, sometimes light, sometimes darkness. The illustrious Young was the first to applaud the success of his young rival, and showed him a kindness which never changed.

Thus, thanks to the use of two-mirror experiment, the theory of Dr. Young (that is to say, the complete analogy of the luminous ray and the sound wave) is firmly established.

Moreover, Fresnel's theory of diffraction shows the cause of their dissimilarity; light is propagated in straight lines because the luminous waves are extremely small. On the contrary, sound is diffused because the lengths of the sonorous waves are relatively very great.

Thus vanished the terrible objection which had so much tormented the mind of great Newton.

But there remained still to explain another essential difference between the luminous wave and the sonorous wave; the latter undergoes no polarisation. Why is the luminous wave polarised?

The answer to this question appeared so difficult that Young declared he would renounce seeking it. Fresnel worked more than five years to discover it; the answer is as simple as unexpected. The sound wave cannot be polarised because the vibrations are longitudinal; light, on the other hand, can be polarised because the vibrations are transverse, that is to say, perpendicular to the luminous ray.

Henceforth the nature of light is completely established, all the

phenomena presented as objections to the undulatory theory are explained with marvellous facility, even down to the smallest details.

I would fain have traced by what an admirable suite of experiment and reasoning Fresnel arrived at this discovery, one of the most important of modern science; but time presses.

It has sufficed me to explain how very great the difficulties were which he had to overcome in order to establish it.

I hasten to point out its consequences.

You saw, at starting, the purely physiological reasons which make the study of light the necessary centre of information gathered by human intelligence. You judge now, by the march of this long development of optical theories, what preoccupations it has always caused to powerful minds interested in natural forces. Indeed, all the phenomena which pass before our eyes involve a transmission to a distance of force or movement; let the distance be infinitely great, as in celestial space, or infinitely small, as in molecular intervals, the mystery is the same. But light is the agent which brings us the movement of luminous bodies; to fathom the mechanism of this transmission is to fathom that of all others, and Descartes had the admirable intuition of this when he comprehended all these problems in a single mechanical conception: here is the secret bond which has always attracted the physicists and geometers towards the study of light. Looked at from this point of view, the history of optics acquires a considerable philosophical importance; it becomes the history of the successive progress of our knowledge on the means that nature employs to transmit movement and force to a distance.

The first idea which came to the mind of man (in the savage state) to exercise his force beyond his reach is the throwing of a stone, of an arrow, or of some projectile; this is the germ of the theory of emission. This theory corresponds to a philosophical system, which assumes an empty space in which the projectile moves freely. At a more advanced degree of culture, man, having become a physicist, has had the more delicate idea of the transmission of movement by waves, suggested at first by the study of waves, afterwards by that of sound.

This second way supposes, on the other hand, that space is a plenum; there is no longer here transport of matter; particles oscillate in the direction of propagation, and it is by compression or rarefaction of a continuous elastic medium that movement and force are transmitted. Such has been the origin of the theory of luminous waves; under this form it could only represent a part of the phenomena; it was, therefore, insufficient.

But geometers and physicists before Fresnel did not know of any other undulatory mechanism in a continuous medium.

The great discovery of Fresnel has been to reveal a third mode of transmission quite as natural as the preceding one, but which offers an incomparable richness of resources. These are the waves of transverse vibrations excited in an incompressible continuous medium, those which explain all the properties of light.

In this undulatory mode the displacement of particles brings into play an elasticity of a special kind; this is the relative slipping of strata concentric to the disturbance which transmits the movement and the effort. The character of these waves is to impose on the medium no variation of density as in the system of Descartes. The richness of resource mentioned above depends upon the fact that the form of the transverse vibration remains indeterminate, and thus confers on waves an infinite variety of different properties.

The rectilinear, circular, and elliptical forms characterise precisely the polarisations, so unexpected, which Fresnel discovered, and by the aid of which he has so admirably explained the beautiful phenomena of Arago produced by crystallised plates.

The possible existence of waves, which are propagated without change of density, has profoundly modified the mathematical theory of elasticity. Geometers found again, in their equations, waves having transverse vibrations which were unknown to them; they learnt, besides, from Fresnel, the most general constitution of elastic media, of which they had not dreamt.

It is in his admirable memoir on double refraction that this great physicist set forth the idea that in crystals the elasticity of the ether ought to vary with the direction, an unexpected condition and one of extreme importance, which has transformed the fundamental bases of molecular mechanics; the works of Cauchy and Green are the striking proofs of it. From this principle Fresnel concluded the most general form of the surface of the luminous wave in crystals, and found (as a particular case) the sphere and ellipsoid that Huygens had assigned to the Iceland spar crystal. This new discovery excited universal admira-

\* The Bakerian Lecture, "On the Theory of Light and Colours." By Thomas Young. Phil. Trans. of the R.S. for the year 1802.

tion amongst physicists and geometers; when Arago came to expound it before the Académie des Sciences, Laplace, who had been such a long time hostile, declared himself convinced. Two years later Fresnel, unanimously elected a member of the Academy, was elected with the same unanimity foreign member of the Royal Society of London; Young himself transmitted to him the announcement of this distinction, with personal testimony of his sincere admiration.

The definite foundation of the undulatory theory imposes the necessity of admitting the existence of an elastic medium to transmit the luminous movement. But does not all transmission to a distance of movement or of force imply the same condition? To Faraday is due the honour of having, like a true disciple of Descartes and Leibnitz, proclaimed this principle, and of having resolutely attributed to reactions of surrounding media the apparent action at a distance of electrical and magnetic systems. Faraday was recompensed for his boldness by the discovery of induction.

And, since induction acts even across a space void of ponderable matter, one is forced to admit that the active medium is precisely that which transmits the luminous waves, the ether.

The transmission of a movement by an elastic medium cannot be instantaneous; if it is truly luminous ether that is the transmitting medium, ought not the induction to be propagated with the velocity of luminous waves?

The verification was difficult. Von Helmholtz, who tried the direct measurement of this velocity, found, as Galileo formerly, for the velocity of light a value practically infinite.

But the attention of physicists was attracted by a singular numerical coincidence. The relation between the unity of electrostatic quantity to the electro-magnetic unit is represented by a number precisely equal to the velocity of light.

The illustrious Clerk-Maxwell, following the ideas of Faraday, did not hesitate to see in the relationship the indirect measure of the velocity of induction, and by a series of remarkable deductions he built up this celebrated electro-magnetic theory of light, which identifies in one mechanism three groups of phenomena completely distinct in appearance, light, electricity, and magnetism.

But the abstract theories of natural phenomena are nothing without the control of experiment.

The theory of Maxwell was submitted to proof, and the success surpassed all expectation. The results are too recent and too well known, especially here, for it to be necessary to insist upon them.

A young German physicist, Henry Herz, prematurely lost to science, starting from the beautiful analysis of oscillatory discharges of Von Helmholtz and Lord Kelvin, so perfectly produced electric and electro-magnetic waves, that these waves possess all the properties of luminous waves; the only distinguishing peculiarity is that their vibrations are less rapid than those of light.

It follows that one can reproduce with electric discharges the most delicate experiments of modern optics—reflection, refraction, diffraction, rectilinear, circular, elliptic polarisation, &c. But I must stop, gentlemen. I feel that I have assumed too weighty a task in endeavouring to enumerate the whole wealth which waves of transverse vibrations have to-day placed in our hands.

I said at the beginning that optics appeared to me to be the directing science in modern physics.

If any doubt can have arisen in your minds, I trust this impression has been effaced to give place to a sentiment of surprise and admiration in seeing all that the study of light has brought of new ideas on the mechanism of the forces of nature.

It has insensibly restored the Cartesian conception of a single medium refilling space, the seat of electrical, magnetic and luminous phenomena; it allows us to foresee that this medium is the depository of the energy spread throughout the material world, the necessary vehicle of every force, the origin even of universal gravitation.

Such is the work accomplished by optics; it is perhaps the greatest thing of the century!

The study of the properties of waves, viewed in every aspect, is therefore, at the present moment, the most fertile study.

It is that which has been followed in the double capacity of geometer and physicist by Sir George Stokes, to whom we are about to pay so touching and deserved a homage. All his beautiful researches, both in hydrodynamics, as well as in theoretical and practical optics, relate precisely to those transformations which various media impose on waves which traverse them.

In the many phenomena which he has discovered or analysed, movements of fluids, diffraction, interference, fluorescence, Röntgen rays, the

dominant idea, which I pointed out to you, is always visible; it is that which makes the harmonious unity of the scientific life of Sir George Stokes.

The University of Cambridge may be proud of the Lucasian Chair of Mathematical Physics, because, from Sir Isaac Newton up to Sir George Stokes, it has contributed a glorious part towards the progress of Natural Philosophy!

A. CORNU.

#### CALCIUM CARBIDE AND ACETYLENE.

The Meran Carbide Works have succeeded in manufacturing carbide on a commercial scale of higher quality than the usually accepted standard of 300 litres of gas per kilo of carbide. Guidé, of the Ecole de Physique et de Chimie de la Ville de Paris, reports that the carbide from this factory gives the following results upon analysis:—

##### PHYSICAL CONSTANTS.

Density .....	2.22
Good crystalline quality.	
Crystals, large, of chocolate or steel-blue colour, with metallic, red-brown lustre.	

##### CHEMICAL COMPOSITION.

Calcium carbide .....	94.2 per cent.
Calcium .....	0.9 "
Carbon .....	0.6 "
Carbonate of silicon .....	2.8 "
Undetermined .....	1.5 "

100 per cent.

Gas generated per kilo..... 332 litres.

##### ANALYSIS OF THE GAS GENERATED.

Acetylene .....	99.508
Methane .....	0.040
Hydrogen .....	0.064
Carbonic oxide .....	0.084
Nitrogen .....	0.230
Ammonia .....	0.032
Sulphuretted hydrogen.....	0.018
Hydrogen phosphide.....	0.006
Silicon hydride.....	no definite traces
Not analysed .....	0.018

100—

The monthly circular of the Carbide and Acetylene Association, Berlin, states that the prices of carbide have fallen all round. Carbide may be bought, in Berlin, at 43s. to 47s. per 100 kilos, including packing. The wholesale price, free in Hamburg or Bâle, is 32s. to 35s., or 37s. 6d. to 40s. for small parcels.

#### A NEW MICROSCOPE LAMP.

It may be of interest to those who practise photo-micrography to learn that a new lamp will shortly be placed upon the market by Ed. Weaster, of Berlin. The *Archiv für Wissenschaftliche Photographie* describes it as a ring-shaped incandescent electric lamp, which can be attached to the tube of the microscope concentrically. A screw attachment is provided for adjusting the distance, and an annular shade with parabolic mirror concentrates the light upon the object. The great advantage of this apparatus is uniform and intense illumination.

#### DISSOLVING EFFECTS WITH SINGLE LANTERNS.

The dissolving of views by means of the optical lantern dates back from the year 1811, when H. Langdon Childe created no small sensation by publicly exhibiting them for the first time; and it was not until about the year 1837 that Mr. Dancer, of Manchester, first practically introduced the projection of views by means of the limelight, as well as substituting photographic transparencies for the hand-painted pictures, which up to that time had been employed in all magic lanterns.

The dissolving of one view into another was then effected by means of two lanterns, although it would appear that for some time Childe kept the secret to himself, and, notwithstanding that thousands of attempts have been made during the last fifty years to produce an equally satisfactory effect by means of single lanterns, it cannot be said that, up to

the present day, any single lantern or carrier has been produced that yields the same delightful effects as were obtained in early years by means of cutting off the light from one lantern whilst at the same moment that from another lamp was made to fall upon the screen.

The means at first employed by Childe were practically the same as we see in use at the present day, when oil lamps are used as the radiant, viz., by passing a metal comb across the front of the objectives, whereby the light from one lamp is made to blend one picture into another without any seeming increase or decrease of illumination on the screen, and later on, after the limelight had been fairly established as the light of the future in projection work, the single-plug dissolver, invented by Mr. Noton, and of which the first description was made public by *THE BRITISH JOURNAL OF PHOTOGRAPHY*, in March 1864, may be said to have solved the problem, in so far as two or more lamps are concerned, for all time coming.

To attempt to enumerate a tithe of the methods that have been suggested during the last fifty years for the obtaining of dissolving effects by means of single lanterns and carriers would indeed be a task of no light order; for both in this country, as well as on the Continent and the United States of America, attempts after attempts have been made, and no doubt in some instances extremely clever pieces of mechanism have been devised; but they all come short of the beauty shown by cutting off the gas, or light, from one lantern whilst that from the other is being introduced, and hence, in any high-class lantern entertainment in which dissolving views form a part, it is necessary to employ a double or triple decker.

With the introduction of photographic transparencies however, in lieu of the old-fashioned hand painted slides, there came a gradual falling off in the popularity of the old double and triple deckers, and single lanterns, by reason of their suitability for illustrating lectures, as well as for educational purposes, have for a great part taken their place, and hence the amount of thought bestowed upon the improvements of the older forms of carriers used in single lanterns, the fruits of which we see in several of the admirable pieces of mechanism that now form part of a first-class single lantern outfit.

Among those who have done much to popularise the single lantern within recent years may be mentioned the names of W. J. Chadwick, Mr. Lancaster, Mr. Beard, Mr. Tyler, Mr. Hughes, and a host of others, among whom are many amateur mechanics, notably Mr. Alexander Robb, of Gourcock, who some years ago not only designed but personally made a form of carrier for his single lantern, which has, perhaps, come as near as possible yielding an effect similar to the cut-off method when mechanical dissolvers are employed, but which, from some reason or other, has never been seen in public use.

In lantern projection it is a well-recognised rule that the screen ought never to be shown without a picture on it, the reason for this, no doubt, being due partly to the fact that any view following an absolutely white disc of dazzling brightness is certain to lose in brilliancy, more or less, when at first it comes before an audience; and, acting on these lines, carriers have been designed which momentarily cut off the light entirely whilst a slide is being changed, and with some this form of carrier is much appreciated. On the other hand, there are those in which the light is not cut off to any extent, but in which the coming slide is made to pass rapidly in front of and over the face of the slide that has been shown upon the screen, the distance in front of which the entering slide is made to run yielding a slight out-of-focus effect that resembles to a certain extent the effects produced by cutting off the light from one lamp whilst that from another is being admitted. Among these forms of carriers may be mentioned that of Mr. Beard, which, although somewhat costly, works smoothly and is very effective.

In Mr. Robb's design, which only very few in this country have seen, the effect is produced in an entirely different manner. Mr. Robb, taking as his model that of the iris diaphragm, applies a small hood to the front of the objective, in which is contained a number of semi-transparent segments, that are caused to open and close just like an iris diaphragm movement. These segments are actuated by the same movement of the carrier which pushes home and withdraws the slides, the movement being communicated to the diaphragm by means of a nicely adjusted lever and little chains attached to the diaphragm in front of the lens. In the hands of Mr. Robb this carrier works beautifully, and it is a pity it is not better known and more in use.

In Mr. Beard's carrier, where one slide is introduced and made to pass in front of the one being shown, there are many extremely good points, and there is no doubt it marks a distinct advance in single-lantern working. Personally, the writer has used this form of carrier since its introduction, and it has given unbounded satisfaction, even among those who claim to know everything about lantern projection. In using this carrier, however, much improvement may be effected by a simple alteration in the slides, which any one can perform who is making up a special set of transparencies for lecture purposes.

The only drawback to this form of carrier (if, indeed, it can be deemed a drawback affecting the carrier) lies in the appearance of the dark bands which cross the slide when a new one is being introduced across the face of the one in the lamp. Of course, this dark streak or band is caused by the opacity of the mask and binding at the edge of the slide that is being inserted. For a time, when using this carrier, I tried to overcome this

appearance by attaching a semi-transparent screen, that was actuated by the same movement that inserted and withdrew the slides; but I never could get my arrangement to work as sweetly as the carrier would do without any attachments, and so one night I put on my thinking cap, determined to solve the problem, and, after a little thought, I managed it thus:—The opaque bar was caused by the binding and mask of the slide, and it struck me all of a heap to make up my lecture sets without any masks, and to bind the cover glasses to the slides at the top and bottom only, and, in some cases, at the corners. This at once got over the difficulty; but, in order to show all the slides in the set as if bound up in the same shape of mask, I got a series of thin brass diaphragms cut out in varying shapes, rounds and cushions, &c., and of different sizes, from 2½ to 2½-inch apertures, and by attaching one of these metal plates to the back of the carrier every slide was made to register exactly, and appear the same size and shape of mask, as well as yielding as nearly as possible a dissolving effect as any single lantern can be made to give.

In adopting a carrier of this description it has been urged that such can only be used from one side of the lantern. This is quite a mistake. Bard's carrier can be used either right or left, and in this lies one of its advantages. If the lantern has to be tilted upwards, as is often the case when working from the floor of a hall on to the screen erected on a platform, the best position is certainly to work from the right of lamp; simply because, owing to the construction of the guides of the carrier, the slide of its own accord falls backward in its proper position in the grooves, and the plunger never misses in driving it exactly into position. On the other hand, if the lantern be tilted downwards, as is often necessary when working from a gallery on a screen at a lower elevation, the slide is certainly liable to lean forward in its runner, and, unless an operator is very careful, the plunger may not carry the slide home perfectly; but, with care, any one knowing the working of this carrier, such need never occur. Whenever, however, a strange operator is at the lamp, and the tilting is downward, I have found it safer to reverse the carrier and work from the left of the lantern. By this means the slides are inserted in exactly the same runners, in the same way, only the forcing arms and lever will drive the slide forward instead of back, but the result is quite the same in the lantern, and the carrier will now work tilted up or down in just the same perfect manner.

It has often been claimed that a good carrier is the backbone of a single lantern outfit, and there is much truth in the statement. The old-fashioned go-and-return carrier is, no doubt, sure and simple, but, to my mind, the slides appearing first from one side, then another, never was an elegant way of showing pictures, and where such is shown alongside one of the modern forms of pleasing change carriers (for, truly, dissolving is too much to claim for any single form of lamp) the contrast is very great indeed, and the comfort all in favour of the mechanical carrier.

For lecturing purposes, pure and simple, the single lantern has quite taken the place of binoculars, and, now that the cinematograph has usurped the place of the triple decker, it looks as if the old-fashioned, but highly enjoyable, entertainment of dissolving views will, in a few years, be a thing of the past. Not so, however, in single lantern work when such is practised with first class apparatus in competent hands.

It is often urged that single lanterns fail occasionally, in that the limes give out during a lecture, but in recent years opticians are providing better limes, or, at least, a quality that withstands the high-pressure jets far better than the limes of former years, and a well-preserved lime in the hands of a clever operator will run a whole evening without giving any anxiety in lecture projection, where such extremely high pressure as is found necessary in cinematographic work is not required.

A. T. NEWTON.

#### LIGHTHOUSE ILLUMINANTS.

In a communication to the *Times*, Professor W. F. Barrett, of Kingstown, Dublin, refers to the question whether the old illuminants for lighthouses are not superior to the electric arc. He writes: "The statement made by the President of the Board of Trade, in reply to a question put to him in the House of Commons by Mr. Field, as to the inferiority of the electric light to oil or gas as a lighthouse illuminant in foggy weather, is a matter of no slight public importance. For Mr. Ritchie's answer affirming this inferiority under certain circumstances, just those circumstances when the value of a lighthouse is put to a crucial test, may be taken to indicate that the Elder Brethren of the Trinity House have been impressed by the weight of evidence which has reached them in favour of the older illuminants."

Those of us who have had the opportunity of examining this question from a scientific point of view have long since come to the conclusion that the employment of the electric arc for lighthouse purposes is a serious mistake, and should no longer be continued. In clear weather other lighthouse illuminants are amply sufficient in power, and the electric light is very apt to mislead the sailor as to his distance from the light, whilst in hazy or foggy weather repeated observations, both of mariners and scientific men, have shown the inefficiency of this light, even of the most powerful electric arc in a lighthouse of the first order. This may be due in part to the fact that rays of high refrangibility, such as are emitted by the arc light, are more largely absorbed by a fog than

rays of lower refrangibility, such as are emitted by oil or gas. Another and perhaps more potent cause appears to be in the very condition which gives the arc light its great value for ordinary optical purposes, namely, its concentration in a minute area compared with oil or gas; this would seem to be a positive disadvantage in a lighthouse illuminant in foggy weather. In support of this statement, I would refer to the Parliamentary paper on lighthouse illumination; see especially the "Return on the subject of Lighthouse Illuminants" February 1893.

I may perhaps quote a paragraph from a letter of mine, dated December 1892, which appears in the return I have just referred to. After a series of observations from my house across the Bay of Dublin (a distance of some six miles) upon the performance of the "giant lens" which Mr. Wigham had then introduced for his admirable system of lighthouse illumination, I remarked: "The experiments and observations in which I have taken part in preceding years have convinced me of the unquestionable superiority in fog-penetrating power of a large and brightly illuminated area over an intense point of light or sharply defined beam such as is furnished by the electric light." Subsequent observation and inquiry have confirmed the view I then expressed, and recently, when in the Isle of Wight, a similar opinion was expressed to me by competent observers as to the comparative uselessness in foggy weather of the splendid electric light at St. Catherine's Point. This view is amply supported by the evidence of numbers of practical seamen contained in the Parliamentary paper I have mentioned. Here, for instance, is the opinion of Captain Threlfall Bragg, R.N.R., the well-known nautical assessor of Liverpool, who, referring to the very Lizard lights with respect to which Mr. Field put his question in the House, says:—

"When I was in command of the steamship *Anterior*, bound round from London to Liverpool, at night, a short distance off Lizard Point, a fog came on; as we approached the point we heard the sound of the Lizard fog siren. The two lights on the Lizard are powerful electric lights, which we were anxiously on the look-out for, but we were unable to see them, as they were completely obscured by the fog siren, and only passing at a safe distance outside the dangers lying off the point."

Several new lighthouses are, I believe, in course of erection around our coasts, and it is earnestly to be hoped that the lighthouse authorities will take steps to place in these lighthouses the illuminant which experience has proved to be of the greatest service to the mariner. For my own part, and speaking as an unofficial and independent observer, I entirely agree with the opinion of the former distinguished scientific adviser to the Trinity House, Professor Tyndall, that, so far, the multi-form gaslight, with which the name of Mr. Wigham has so long been associated, has not been superseded as a lighthouse illuminant.

#### BALLOONING AND PHOTOGRAPHY.

MR. PERCIVAL SPENCER, aeronaut, and Mr. Pollock left the Crystal Palace by balloon on Saturday afternoon, July 29, with the intention of crossing the English Channel. A favourable N.W. wind was blowing at the time of the start, and the journey was accomplished with complete success. Mr. Spencer supplied the following narrative of the voyage to the *Daily Telegraph*:—

"At 2.30 we left the Crystal Palace, and were moving over Penge, Bromley, Beckenham, Bickley, and other picturesque suburbs. I carried a Frena camera, with forty photographic films, which I proceeded to expose. Now commenced a voyage over agricultural land, with distant views of heath, villages, and undulating ground, rendered flat and chess-board-like by the altitude we had reached. Distant gunshots were heard—sportsmen's shots at rabbits, perhaps, yet the stillness and tranquillity usual to a balloon voyage pervaded all. On looking ahead, we were glad to perceive that we were making almost direct for Knockholt Beeches, which form a landmark direct south-east from the Crystal Palace, and therefore on the direct route across Channel. For an hour we travelled thus, and at 3.30 p.m. we had reached Sevenoaks.

"The balloon rose to an altitude of 5000 feet, indicated by the aneroid barometer. Then Tonbridge and Tonbridge Wells were crossed. Our altitude we maintained for some time, the heat of the sun's rays causing the gas in the balloon to become rarefied, whilst the masses of cloud below kept the air in the lower strata cool, and prevented the balloon descending into them. As the sun shone on these clouds, the effects were various, beautiful, weird, and always wonderful. Perhaps the prettiest sight was when the balloon, rising from the rolling billowy mass, left a shadow sharply silhouetted on the clouds, and surrounded by a ring of rainbow-coloured tints.

"Until 4.30 the coast line was shut out from our view, and then through the clouds a distant white line marked the termination of the land, perhaps fifteen miles ahead. Between 4.30 and 5 o'clock we had to decide the important question of whether a descent should be made in England, or whether we should attempt to cross the sea. The balloon continued to maintain its altitude, and we noted, by fixing our gaze upon the earth and consulting a pocket compass, that the direction was due south-east. It could not be better from a theoretical point of view. We had used four out of the ten bags of sand, each weighing half a hundred-

weight, with which we had provided ourselves before starting. As the coast line came nearer, we observed that we were crossing the twin towns of Hastings and St. Leonards. We then decided not to open the valve and descend, but to continue our journey across.

"At 5.3 p.m. we were passing out to sea, and again I brought the camera into requisition. Looking backwards, to the right lay the coast line to Dungeness, a sandy prominence jutting out into the sea, and beyond the white cliffs to Dover. Immediately behind were the old and new towns of Hastings. Thence the coast line continued past Bexhill to Eastbourne and Beachy Head—the latter prominent, but the towns almost indistinguishable owing to distance and cloud. By 5.20 the clouds had completely shut out the English coast. Then, after rising to 7000 ft., the balloon dropped to 2000 ft., and it required two and a half of our remaining six bags of ballast to get a lift once more into the sunshine. By six o'clock we had risen to 8000 ft. After a consultation we decided not to again permit the balloon to descend into the cold lower air lest we exhausted our sand and found ourselves unable to get the balloon to rise again.

"Looking now over the clouds into clear blue sky, Mr. Pollock was the first to discover the white line of cliffs which marked the boundary wall of France. Far, far away it was, yet this was our destination. By dint of careful and constant discharge of ballast in small quantities, we maintained the equilibrium of the balloon, and increased its altitude to 9000 feet. At this height the vast solitude of the sea was wonderfully impressive. The hum of the waves could no longer be heard. From the direction of the smoke of a large steamer near Hastings we had seen that the wind on the surface of the water was coming from the west, whilst we above were in a north-westerly current. At 7 p.m. we were at a height of 7000 feet, and apparently very little nearer the other side. Our stock of ballast was fast diminishing; in fact, we had only one full bag left, and, in accordance with our decision to maintain the altitude of the balloon, this was being steadily parted with. We gathered together all the empty sand bags (the ten weighing some pounds), prepared to utilise them as ballast when all the sand should have run out. At 7.30 p.m. we were at 10,000 feet, being presumably borne onwards slowly, yet having no certain means of detecting whether we were moving or not.

"We could not observe any ships, but now there was no doubt about the coast line. It was perfectly clear ahead, and we could even distinguish the mouth of the river Somme, with the low-lying coast to the left and the long white range of cliffs to the east. Still, it was quite a debatable question whether we should be able to reach the coast without touching water. We knew that, if we were unable to maintain the altitude, if the balloon once sunk below the level of the clouds, it might commence a rapid downward course which our ballast being gone, we should be powerless to prevent. At 7.35 the last sand ran out. We maintained equilibrium by throwing over first all the empty sand bags, and then the linen wrapper carried to enclose the deflated balloon after the descent. At 7.40 all extraneous weight had been thrown over, and we were sinking.

"Down dropped the balloon—9000 ft., 8000 ft.—and we were at least ten miles from shore. Save for our two selves, the car was empty. I slung the camera up in the rigging, so that it should be kept dry if our car touched the water. Desperate situations require drastic measures. To prevent the balloon from continuing and increasing the force of its downward career, we decided to unship the anchor and drop it into the sea. The seventy pounds of steel, bar and prongs, were cast overboard, and fell with lightning-like rapidity, whirling as it whirled through the air until it reached the desert d sea, thousands of feet below. Thus lightened, the balloon speedily ascended, reaching its maximum height of 12,000 ft. Having attained this height, it resumed perfect equilibrium, but for a few moments only, for, as the sun disappeared behind the bank of evening clouds—a dark fringe on the distant horizon—and deprived us of the benefit of its heat rays, the balloon began to settle slowly yet surely. To say the least of it, it now became very interesting to watch the French coast, and to wonder whether or not the balloon would reach it. By carefully comparing our position with that of the ships below us, we were convinced that we were on our way to the shore; but now—7.50 o'clock—our balloon had dropped to 8000 ft., and was continuing its downward course. Fortunately for us, our fears were not realised. The loss of the sun's rays did not cause so rapid a drop as we had anticipated, and at 7.55, though descending at the rate of 500 ft. per minute, and with no means to prevent the continuance of our downward course, we still cherished every hope of reaching the shore.

"Towns, harbours, country sides, and land could now be distinguished. At 8 o'clock the white chalk cliffs became perpendicular. We could no longer see the surface of the sea. We were over land, and our height was still 5000 feet. In another five minutes we had descended so low that we looked ahead for a landing-place. We were fast approaching earth, with a large wood in front of us. We opened the valve to hasten our descent before reaching it, and at 8.8 our trail rope touched the ground. A moment or so later our car was bumping the ground a bare hundred feet before reaching the trees. The balloon rose slightly, and was carried on by the breeze, but only for a short distance. We held the valve open, and the course of the fast deflating balloon was at last summarily checked by the knot in the trail rope and the friction of the car upon the rough ground.

"The populace, in the form of capped and bloused agriculturists, arrived in due course. We learned we were at Worncourt, one and a half miles inland, about midway between Dieppe and Tréport. A vehicle was provided, in which the balloon, packed in its car, and ourselves were conveyed to the nearest railway station. We booked the balloon for London by *grande vitesse*, and ourselves took train to Tréport, where we passed the night."

### THE PURIFICATION OF ACETYLENE.

The average composition of acetylene obtained by means of carbides of Swiss and of American manufacture is as follows:—

	American. Per cent.	Swiss. Per cent.
Acetylene .....	99.87	99.87
Phosphoretted hydrogen .....	0.04	0.02
Sulphuretted hydrogen .....	0.02	—
Ammonia .....	0.06	0.04

Carbides of recent manufacture give a gas which contains less sulphuretted hydrogen and no trace of silicuretted hydrogen. The quantity of sulphuretted hydrogen is always less when the generator contains a large excess of water. A judicious choice of raw materials enables us to reduce the amount of ammonia and phosphoretted hydrogen to a few hundredths per cent.; but even such small quantities are still of serious inconvenience.

The method of purification proposed by Frank gives good results: it consists in using acid solutions of certain metallic salts, particularly chloride of copper. A part of the acetylene is transformed into aldehyde.

The author proposes the use of chloride of lime containing a small quantity of an alkaline chromate. The free chlorine is thus absorbed and the acetylene does not undergo any decomposition.

Frank states that the acid solution of the metallic salt which he uses can be placed in an enamelled vessel, and that the quantity of aldehyde formed is very small. He claims that one litre of his solution will purify fourteen cubic metres of acetylene, and that it can be regenerated by boiling, followed by aeration.—*Journ. für Gasbeleuchtung*, xli. [42], p. 683.  
P. WOLFF.

### FLASHLIGHT EXPERIENCES.

My dear first, as a widow who has buried several husbands would say, represents an "at home." Not one of the "fash-nable" "society" affairs called by that name, where every one feels the reverse of at home, but my own family and myself at home one Sunday afternoon.

The directions said, "Shield your eyes from the light," so I thought I must; but later experience taught me this was unnecessary. Tell your sitters not to look directly at the flash, and all will be well. There were no outside blinds on the windows, so we drew down the dark brown opaque curtains as close as possible; all took our positions; I drew the slide, uncapped the lens, lit the Scovill cartridge No. 2, and dropped into the chair which had been placed ready. The nearly white wall paper and the nearness of the walls in this room greatly assisted the light, which was ample for a normal development.

My second, you will see, was taken in a large hall, with the light far removed from the subject, and, although twice as much flash powder was used, it is only about half lit. But they ordered about six dollars' worth of them at thirty-five cents each for 8 x 10 prints, so I was well paid for my attempt.

My third is a Thanksgiving-day dinner, where everything happened as planned, except that the fuse on the cartridge was not long enough to admit of my getting into the chair in the right foreground, and you will hardly recognise me in the blur above it.

Don't try to be saving of your powder. Use plenty, heaping up one cartridge with part of the contents of another, till you are sure you have enough.

Don't hold the cartridge in your hand when you light it, it would be sure to burn you. Don't fire your powder close to light draperies, or without a large serving tray, or something equally fireproof, under it.

Don't forget to cap your lens and replace the slide before opening up the room to let out the smoke, or your plate will get "too very much exposed," as I once heard a hopeful amateur say.

E. F. PHILLIPS, in the *Photographic Times*.

### DIFFICULT CLOUDS MADE EASY.

A FREQUENT method of obtaining a general impression of a photographic exhibition is to stand in the centre of the room, or gallery, and to observe what is the predominating feature. Those who during the last year or two have applied this principle, when visiting our leading "Show," will, in all probability, have observed that the majority of the exhibits owe much of their merit and attractiveness to clouds; in fact, without their harmonious skies many of the best pictures would have been unworthy of being "skied" at a travelling peep-show. It is, however, unnecessary

to expatiate upon the advantages of clouds. For the purpose of this article it suffices to accept the hypothesis that they have come and are sure to stay. Also there is no need to more than briefly refer to the usual method of blocking out, or the duster way of inserting clouds, because they are well known and written about in every manual of the most moderate pretensions, so we will proceed quickly. Generally speaking, when our clouds require deeply printing, and we have a number of delicate details appearing above the sky line, even the oldest hand would find the successful carrying out of his desire a difficulty, as the extra degree of density added to the obstructive matter would be at once evident. The following practice will, however, enable anybody to insert any desired effect with easy and certainty.

The procedure is as follows: Take your negative, and make from it a positive, and then select a suitable cloud negative (which should be preferable on celluloid). In a printing frame place the cloud film on the top of the positive, and again, on that, a slow plate of any kind that you are in the habit of using. After fastening up the frame, print by gaslight, using your focussing cloth, or a piece of paper, as a rough mask, and keep it moving in the customary manner, so as to avoid any harshness in the horizon line, and develop in the ordinary way. You now have two positives, one of the subject, and another of the sky, which latter will have blank spaces even where the most delicate tracery of foliage, or anything else, juts out beyond the landscape proper.

Nothing now remains but that the photographer should carefully superimpose the cloud positive upon the picture positive in such a manner that the protruding bits fit exactly into the blanks in the sky positive. This is exceedingly easy to do even by the most inexperienced.

Prior to uniting the two glasses put a few spots of any ordinary mountant on the edges of one of them, so that, when you have got both plates in proper register and placed them on some flat surface, they will dry and adhere sufficiently well to stand any reasonable amount of rough usage.

From this combination it is only necessary to make a negative, which must perforce be done by copying in the camera, seeing the picture is inside the two glasses. This cannot be considered a disadvantage, as any size of negative may naturally be produced, and which will be complete in every sense, and from which any number of prints can be made with an exactness that would be manifestly impossible by any of the ordinary uncertain modes of double printing at present customary.

The idea may not be entirely novel, but, to the best knowledge of the writer, it is not as widely known as it deserves to be. For carbon printing it is an enormous advantage to have one's clouds on the negative, seeing the process is a blind one, and, when working the bromide or any other form of developing process, its utility will be at once admitted.

PERCY SHEARD.

### A VILLAGE LIGHTED BY ACETYLENE.

ST. MICHAEL'S, a village in Kent, within sight of the steeple which is in some roundabout way supposed to be the cause of the Goodwin Sands, has led the way. Tenterden itself is lighted by coal gas, but the company's mains do not reach St. Michael's, and the village has been paying one-sixth of the lighting rate of the borough without reaping any benefit in illumination. The village has had to grin and bear it, for the place is not large enough for ordinary gasworks.

The invention of acetylene gas, however, and the special applicability of Messrs. Thorn & Hoddle's system to large or small requirements, has given the village its opportunity. Half-a-dozen shareholders, with a capital of 150*l.*, have set up an installation capable of supplying continuously eighty burners of twenty-five candle-power each, and the only attention which is required is that of one person for about twenty minutes a day. Included in this 150*l.*, moreover, are the expenses of providing six public lamps and 651 yards of piping. It is calculated that the acetylene gas will come cheaper to the consumer than ordinary coal gas. A lady, by the bye, is the managing director of the little company.

"To many microscopists the terms 'one quarter inch,' or 'one half inch,' as applied to their objectives, convey the idea that, when in focus, the object is at a distance of a quarter inch, or a half inch, from the front lens. They confound the equivalent focal length of the objective with the working distance. As a matter of fact, the latter is always considerably less than the former. The determination of the working distance of an objective is a point of considerable importance, and therefore all microscopists should make themselves familiar with the method of calculating it. The following simple device will be found useful for estimating the working distance of objectives that are not higher than one-twelfth inch. Make a long thin wooden wedge, ten centimetres in length along the base, and twenty millimetres in perpendicular height. Focus a diatom on a glass slip without a glass cover, and then carefully push the wedge along the glass slip until it touches the objective. The thickness of the wedge at the point of contact will represent the working distance of the objective."—M. J. H. COOKE in *Knowledge*.

## LANTERN MEMS.

THE near approach of the lantern season is heralded by the issuing of the publishers' lists of new photographic slides. As Messrs. York & Son are always to the fore, I cannot do better than call attention to their new subjects first. Their sets are invariably comprehensive, and the Continental and other views not only form good pictures, but are useful from an instructional point of view, for many are suitable for the illustrations necessary in teaching physiology, while in the popular educational series is a set of *Shakespeare's Avon, In the Footsteps of Cromwell*, and some half-dozen supplemental maps; also one on *Human Vision*, which includes illustrations specially referring to refraction, chromatic aberration, astigmatism, binocular vision, persistence of vision, and other subjects interesting to photographers and lanternists.

THE general sets deserving of special mention are the following: *Cairo and the Nile, Past and Present; Life and Scenes in Palestine; Jerusalem, Ancient and Modern; The Cities of Berlin and Dresden; Sicily*, and a number of life-model sets, and some forty photographs of *New London*. The illustrated songs which are always popular at entertainments have been added to as follows: *The Lost Chord, The Angels' Promise, Ben Bolt, Coming through the Rye, and The Star of Bethlehem*.

MESSRS. VALENTINE, G. W. Wilson & Son, and West & Son, have each added largely to their lists, and produced sets and series of slides of the well-known character of distinctive work for which each is noted. When one looks at the large catalogues of slides now published, one cannot help contrasting the position of the lantern world with what it was a quarter of a century ago, and adding to this the thousands of slides made from private or amateurs' negatives makes the position of the lantern-slide dealer one that necessitates the possession of an expanding store-room. If the publication goes on at the rate it has done in recent years, premises constructed on the plan of the glass houses in Guernsey would have to be the order of the day, if land were available for the purpose; but, unfortunately, in London and the large cities and towns the only way in which premises can extend is upwards.

I ALWAYS like to hear of successful work in new fields being accomplished, and recently I have had an account given me of an

outdoor lantern exhibition to the fishermen, coastguard, and soldiers in the fishing town of Kinsale, in the south of Ireland. The apparatus was the gift of the Baroness Burdett Coutts, and was all specially arranged for convenience of work at some distance from the place of storage, the whole of it packed away in a covered hand cart that could be drawn down to the quay where the exhibitions were given, places being made in the cart for gas cylinders, screen-support, slides, &c. The exhibitions are given by the local commander of the coastguard, who has been most enthusiastic in the work, and taken great pains to entertain and instruct those who have little opportunity of recreation of an intellectual order. Mr. J. H. Steward, of the Strand, supplied the apparatus and slides, and had the hand cart specially built for the purpose. It bears a plate, stating that the apparatus is in charge of the commander of the coastguard for the time being, and held, under certain conditions, for the benefit of sailors, fishermen, and soldiers, as mentioned above.

It is quite refreshing to come into business contact with those that follow the sea as a profession, and especially officers in Her Majesty's Navy, for there is a certain charm in the "breeziness" of their manner that carries all before it. Besides having a practical grasp of most scientific subjects, a knowledge of mechanics and fearlessness of anything dangerous, it is quite amusing to hear "one of the Queen's naves" talk, but I was just a wee bit staggered with the remark, "I suppose I can learn all about the lime light in five minutes." "Well, hardly," I replied, "suppose we say a quarter of an hour," and it was done.

I MENTION this, that would-be users of the lime light may understand that, given simple and efficient apparatus, a limelight lantern, even of the high-pressure-mixed-gasjet order, is not such a fearful and wonderful thing but that the operation of it is such that any one of average intelligence can quickly master it, if—and this is a big if—it is followed up by a lot of practice. It is because lantern workers do not make the opportunity for practice, and so become efficient that the best results are not obtained in public. My advice to all purchasers and users of apparatus is, and always has been, never go into public until you have had at least six rehearsals and mastered the details of your gas supply, fitting up, obtaining a proper light, and have accustomed yourself to the routine of changing the slides, turning the lime, regulating the light, and cutting off or dissolving, so that you can accomplish it without fluster. Coolness is a great qualification in an operator, for under most advantageous circumstances, operating is a warm job, and, if fluster is imported into the work, then it reduces the amount of pleasure given to the audience, and certainly produces uncomfortable feelings in the operator.

THE designs for lanterns this season do not seem to be much altered from last, and the departures in design tried a few years since apparently fail to secure a large number of supporters. There

is nothing like having a reasonable size body to contain the illuminants, and permit of properly getting the hand inside to reach condensers, adjust lime light jet or arc lamp, and, above all, to obtain sufficient air space to keep reasonably cool, and permit of a fresh air current passing through; the stage to be sufficiently steady to prevent the carrier shaking when changing slides, and so obviate any apparent movement of the view or projection on the screen; the front lens to be of such a focus as to be at a reasonable distance from the screen for the size disc required, and, what is not as often considered as it might be, the focal length of the condenser should be proportionate to the objective, for the very short-focus condensers suitable for the oil light are not at all satisfactory when long-focus objectives are employed for long-range projections. G. R. BAKER.

### PHOTOGRAPHY OF SOUND WAVES BY THE "SCHLIEREN METHODE."

[Abstract of a paper contributed by the author to *The Philosophical Magazine*.]

I HAVE always felt that the very beautiful optical method devised in 1867 by Toepler,\* for the study of "Schlieren," or strisæ, is not as well known outside of Germany as it deserves to be, and trust that the photographs illustrating this paper are sufficient excuse for bringing it before the readers of the *Philosophical Magazine*. Sound waves in air were observed by Toepler, but they have never, to my knowledge, been photographed. When seen subjectively, the wave fronts, if at all complicated, cannot be very carefully studied, as they are only illuminated for an instant, and appear in rapid succession in different parts of the field of the viewing telescope.

It occurred to me that, if these waves could only be photographed, a most valuable set of lantern slides could be prepared for illustrating to students the changes in the form of the wave front after undergoing reflection, refraction, &c.

In teaching the subject of optics we are compelled to resort to diagrams when dealing with the wave front, and the student is apt to get the idea that it is merely a sort of a conception, and that the ray is the real thing. I have found these pictures of sound waves very valuable in checking this notion, showing as they do the bending of the wave front by refraction through a prism, the converging wave from a concave reflector, the secondary wavelets formed by transparent and opaque gratings, the diffraction produced by the edge of an obstacle, and other phenomena connected with wave motion. The apparatus used for photographing the waves is essentially the same as that which Toepler used for viewing them, except that the illuminator has been improved so as to give a much stronger light than the one originally used, which was far too feeble to affect the photographic plate.

Fig. 1.

The general arrangement of the "Schlieren" apparatus is shown in fig. 1. A good-sized achromatic lens of the finest quality obtainable, and of rather long focus, is the most important part of the device. I have been using the object-glass of a small telescope figured by the late Alvan Clarke. Its diameter is five inches, and the focal length about six feet. I have no doubt but that a smaller lens could be used for viewing the waves, but one of at least this size is desirable for photographing them.

This lens is mounted in front of a suitable source of light (in the present case an electric spark), which should be at such a distance that its image on the other side of the lens is at a distance of about fifteen feet.

The image of the spark, which we will suppose to be straight, horizontal, and very narrow, is about two-thirds covered with a horizontal diaphragm, *a*, and immediately behind this is placed the viewing telescope. On looking into the telescope we see the field of

the lens uniformly illuminated by the light that passes under the diaphragm, since every part of the image of the spark receives light from the whole lens. If the diaphragm be lowered, the field will darken; if it be raised, the illumination will be increased. In general it is best to have the diaphragm so adjusted that the lens is quite feebly illuminated, though this is not true for photographic work. Let us now suppose that there is a globular mass of air in front of the lens of slightly greater optical density than the surrounding air, *b*. The rays of light going through the upper portion of this denser mass will be bent down, and will form an image of the spark below the diaphragm, allowing more light to enter the telescope from this particular part of the field; consequently, on looking into the instrument, we shall see the upper portion of the globular mass of air brighter than the rest of the field. The rays which traverse the under part of *b*, however, will be bent up on the contrary, forming an image of the spark higher up and wholly covered by the diaphragm, consequently this part of the field will appear black. It will really be understood that with the long path between the lens and the image a very slight change in the optical density of any portion of the medium in front of the lens will be sufficient to raise or depress the image above or below the edge of the diaphragm, and will consequently make itself manifest in the telescope.

The importance of using a lens of first-class quality is quite apparent, since variations in the density of the glass of the lens will act in the same way as variations in the density of the medium before it, and produce unequal illumination of the field. It is impossible to find a lens which will give an absolute even feeble illumination, but a good achromatic telescope objective is perfect enough for every purpose. A more complete discussion of the operation of the apparatus will be found in Toepler's original paper in the *Annalen*. The sound waves, which are regions of condensation, and consequent greater optical density, make themselves apparent in the same way as the globular mass of air already referred to. They must be illuminated by a flash of exceedingly short duration, which must occur while the wave is in the field of view.

Toepler showed that this could be done by starting the sound wave with an electric spark, and illuminating it with the flash of a second spark occurring a moment later, while the wave was still in

Fig. 2.

the field. A diagram of the apparatus used is shown in fig. 2. In front of the lens are two brass balls, *a, a*, between which the spark of an induction coil passes, immediately charging the Leyden jar, *c*, which discharges across the gap at *e* an instant later. The capacity of the jar is so regulated that the interval between the two sparks is about one ten-thousandth of a second. The field of the lens is thus illuminated by the flash of the second spark before the sound wave started by the first spark has gone beyond the edge of the lens.

To secure the proper time interval between the two sparks it is necessary that the capacity of the jar be quite small. This limits the length and brilliancy of the illuminating spark, and with the device employed by Toepler I was unable to get enough light to secure photographs of the waves. After some experimenting I found that, if the spark of the jar was passed between two thin pieces of magnesium ribbon pressed between two pieces of thick plate glass, a very marked improvement resulted. With this form of illuminator I found that five or six times as much light could be obtained as by the old method of passing the spark between two brass balls.

The spark is flattened out into a band, and is kept always in the same plane, the light issuing in a thin sheet from between the plates.

\*Wied. Ann. cxxxi. p. 33.

By this arrangement we secure a light source of considerable length, great intensity, and bounded by straight edges, the three essentials for securing good results. The glass plates, with the ribbon terminals between them, must be clamped in some sort of a holder and directed so that the thin sheet of light strikes the lens. This can be accomplished by darkening the room, fastening a sheet of paper in front of the lens, and then adjusting the plates so that the paper is illuminated as much as possible. The image formed by the lens will be found to have very sharp, straight edges, on one of which the edge of the diaphragm can be set in such a manner as to allow but very little light to pass when the intervening medium is homogeneous. A very slight change, however, in any portion may be sufficient to cause the entire amount of light passing through that portion to pass below the diaphragm and enter the telescope.

This arrangement of the spark terminals between plates of glass is also convenient for spectroscopic work, as the spark is concentrated into a very narrow bright line, which is fixed in position instead of wandering about, as it is apt to do when passed between uncovered terminals.

For photographing the waves the telescope was removed, and a Zeiss photographic objective put in its place. A vertical board was firmly clamped behind this in such a position that the image of the balls, between which the sound spark passed, would be in focus on a plate held against it. This arrangement was used instead of a camera, because it was necessary to move the plate rapidly during the exposure, to prevent the image of more than one wave being formed on the same place. It was found that simply holding the plate in the hand against the vertical board and advancing it slowly from left to right, at the same time giving it a rapid up-and-down motion, answered every purpose. It must be borne in mind that the image of the 5-inch lens on the plate was only about 13 mm. in diameter, and that the field surrounding it was dark; consequently a large number of images could be secured on a single plate.

These images showed the waves in different stages of development, for the time interval between the two sparks varied between rather wide limits. This was really an advantage, for on a single plate it was possible to pick out a series showing the successive changes in the form of the wave front produced by reflection, refraction, &c.

PROFESSOR R. W. WOOD.

#### CLEANLINESS IN LANTERN SLIDES.

TWENTY-FIVE years ago the making of a lantern slide was a very different matter to that of the present-day procedure by means of a dry lantern plate, and but a small percentage of those who now pose as expert slide-makers know anything about the working of wet collodion and the precautions necessary to ensure the various chemicals working not merely satisfactorily, but especially with a view of turning out slides that were brilliant and absolutely clean from any surface deposit or other defects.

With the modern lantern plate the production of a lantern slide, either by contact or reduction through the camera, is one of the easiest tasks in photography, and the simplicity of the operation has, no doubt, tended to introduce an amount of carelessness which, with wet collodion, would be fatal to the production of work of this kind.

In all lantern-slide work one of the chief essentials to a brilliant picture is the practising of the most scrupulous cleanliness, not only in the manipulation of the sensitive plate, but also in the preparation of the various solutions used. With wet collodion, this was a *sine-quâ-non*, and the using of any unfiltered solution was a thing never dreamed of. How many workers are there at the present day who ever give a thought to the filtering of their solutions when using a lantern dry plate? But very few, I fear; and yet it is by no means an unnecessary procedure if slides are to be turned out that are absolutely clean and free from various defects.

Some, no doubt, may argue that there is no need for such precautions with the modern dry plate; but I venture to assert that between two workers, one of whom studiously attends to the filtering of not only his developing and fixing solutions, but also carefully washes his slides with filtered water, and another who just fires away without such precautions, there will be seen a vast difference in the quality of the results that they turn out.

The difficulty of turning out an absolutely clean lantern slide by means of a dry plate is far greater than many imagine, and in nine cases out of ten defects are attributable to want of cleanliness in the washing of the them after they have run the gauntlet of development and fixing.

But few water supplies are beyond suspicion of containing suspended matter and other impurities, and if any one imagines that in this respect they are better off than their neighbours, and on that account do not require to resort to the tedious operation of using only filtered water for their washing of lantern slides, just let them try the effect of placing a quantity of their "above-suspicion *aqua*" in an ordinary wash basin, before going to bed, into which a teaspoonful of powdered alum has been stirred, and let them note the results when they get up in the morning, and I venture to assert they will have their eyes opened in a manner they little dreamt of. The fact is, that when dealing with such delicate pictures as glass positives, where brightness is of the first moment, no water supply is beyond suspicion of being unsuitable for the washing of same that has not been carefully filtered.

And if so much depends upon the final stage, certainly equal precautions are necessary in the making up of the various solutions used in development and fixing. Over and over again we see the advice given to preserve an old hydroquinone developer for the purpose of yielding vigour or pluck in the development of lantern slides, for which purpose there is no doubt that it is admirably suited; but the use of such a spent developer means the application of such solutions for several minutes' duration of time, and as a general rule these old hydroquinone solutions are never free of sediment, and always throw down more or less surface deposit on the plate that no amount of washing will effectually remove. Cotton-wool has been recommended to swab the surface of a plate free from surface deposits, but surely prevention is much better than cure in a matter of this kind. With a hard horny film of collodion, cotton-wool was regularly employed by old wet-plate workers, and such, to use a common expression, never or very seldom made its presence felt otherwise than by accomplishing what it was intended to perform; but, with a soft gelatine plate, even cotton-wool unskillfully applied to such a surface is very liable to cause scratches and other defects, especially if the temperature of the various solutions be at all high.

Dirty fingers are another fruitful source of defects in lantern slides, and but few workers have any idea how an individual shut up in a dark room will contaminate his fingers, even by the act of merely lifting various bottles or trays and other articles indispensable to the fitting up of a dark room, as well as contracting other injurious matter from the various chemicals he has to finger.

In a well-appointed studio, where the utmost precautions are taken to avoid any contamination when even an ordinary toning operation is being performed, different individuals invariably manipulate the prints at various stages, so that the one toning never brings his or her fingers in contact with anything but the toning bath, and such precautions soon reflect upon the percentage of perfect prints that result from this cleanliness; and, if in ordinary toning of silver prints such cleanliness is found to be required, how much more so when dealing with delicate transparencies?

In working some qualities of lantern plates it is almost impossible for any operator to turn out a large number of slides with his own hands unless special provision be made for a method of working whereby he is able to avoid fingering his hypo during the time development is proceeding. Hence, when any number of lantern slides are being produced, the services of an assistant whose duty is to attend to the fixing alone is always a wise precaution, and the substitution of dipping baths for the old-fashioned flat dishes is a distinct improvement. By using dipping baths there is less liability for the delicate surface to contract deposits; and, if such cleanliness is required up to and including the final washing stage, how necessary also is the need for the exercise of the utmost care in protecting the surface of the slides during the operation of drying?

With wet collodion, dust was ever the bugbear in lantern-slide making, and more especially was this the case when the varnishing stage was reached, and but very few slides indeed ever ran through the ordeal without some noticeable speck or flaw; but with gelatine, of course, this is avoided. Yet it is surprising how many fine slides come to grief during the drying operation from dust alone.

The operation of drying is best performed by rearing the slides end up on a clean linen cloth in a room where but little movement is required. Much ingenuity has from time to time been spent upon the construction of drying boxes or chambers, but for the mere drying of an insensitive plate they are not required. The chief factor to avoid is dust, and the less the plates are fingered or manipulated during the operation of drying the better. I know quite well, with amateur workers especially, the temptation to inspect and gloat over the production of some choice slide is very great indeed, and I know also quite well that at this stage very many good results come to grief from nothing else but the handling of the wet slides, and the sooner any one arrives at a fixed determination to overcome any little weakness during this stage the better will his results turn out.

Cleanliness at every stage is the sheet anchor in lantern-slide production, and once a worker makes up his mind to follow only a rigidly arranged method of seeing that all his solutions are carefully filtered and that no dirt reaches his slides during the operations of washing and drying, so soon will he be gratified at the vast improvement that will be noticeable in his results.

T. N. ARMSTRONG.

### THE ELECTROLYTIC INTERRUPTOR IN X-RAY WORK.

SINCE the publication of my article upon the above subject in THE BRITISH JOURNAL OF PHOTOGRAPHY I have continued to make experiments, the result of which I feel will interest those of your readers engaged in X-ray work.

The passage of the electric supply current through the interruptor is regulated by the following conditions:—

1. The relative sizes of the electrodes.
2. Their distance apart.
3. The specific gravity of the fluid.
4. The length of platinum wire exposed.

In order to obtain any interruptions at all, it is absolutely certain that the lead plate must present a surface many times the area of the

Fig. 3.

platinum wire. That there is no necessity, however, for the large surface of lead used in most interruptors, I have proved by experiment. With a platinum wire (20 B.W.G.) half an inch in length, I tried lead plates offering a surface of from one to thirty-two square inches, and the ammeter (an exceedingly delicate instrument) failed to show any appreciable difference in the amount of current passed.

In order to test the effect of distance between the electrodes, I constructed an interruptor in a glass tank over two feet in length. With a solution of sulphuric acid and water of a specific gravity of over 1015 only a very slight difference in the amount of current passing was noticed, no matter how small or great the distance between the electrodes. With a solution of very low specific gravity (1005) much more current passed when only half an inch apart than when the distance was increased to four inches; between four inches and two feet, however, no appreciable difference could be measured.

So much depends upon the specific gravity of the electrolyte, that too much attention cannot be given to this point. The amount of resistance offered by the interruptor can, by varying the specific gravity of the fluid, be regulated to the greatest nicety, and to such an extent as to render the use of a rheostat unnecessary. The experiments upon which these conclusions are founded were carried through with the assistance of Mr. J. C. Vaudry, the managing director of the Birmingham Electric Supply Company, who kindly placed at my disposal a voltmeter and ammeter of exquisite sensitiveness.

The experiments were made with a nominal 110 volt circuit, which at the time was supplying a regular flow of 119 volts. The arrangement of the apparatus during the experiments will be understood by reference to the diagram (fig. 3). The voltage of the current passing through the primary of the coil was measured by the drop which was registered across the interruptor.

The vessel containing the interruptor was large, and contained 200 ounces of solution. The platinum wire was 20 B.W.G., and half an inch was exposed. The lead plate was 16 square inches and the distance between the electrodes was  $8\frac{1}{2}$  inches.

In the measurements here recorded the rheostat was entirely cut out of circuit, the full 119 volts being passed through the interruptor.

With plain water, specific gravity 1000, the ammeter failed to give any reading, so that less than a quarter of an ampere passed. The voltage across the interruptor showed a drop to 115, thus 4 volts passed through the coil,\* which gave a spark of only half an inch in length. The platinum wire in the interruptor gave off but a few bubbles and did not become red hot. Half an ounce of pure

sulphuric acid was now added (specific gravity 1002). 3 amperes at 5 volts now passed a good supply of sparks 3 or 4 inches in length, passing between the sparkers. Sulphuric acid was now added, half an ounce at a time, until the specific gravity reached 1023, when 8.5 amperes at 13 volts was used. The spark now assumed the violet-blue colour mentioned in my last article, and twisted about between the sparkers, which were placed about 8 inches apart.

A complete record of the experiments will be seen by a glance at fig. 4.

These experiments prove that, with a platinum electrode of fair size, the interruptor can be completely controlled by varying the specific gravity of the solution, and, moreover, that the quantity of acid generally recommended is far in excess of that really necessary. A five per cent. solution, which, with the acid I used, gave a specific gravity of 1048, required, with the same arrangement, an additional resistance of about 5 ohms before it could be used with safety. Under these circumstances, however, matters can be speedily rectified by cutting off a piece of the platinum wire.

From these experiments I concluded that a 220 volt current would be used, which conclusion was subsequently verified.

The length and size of the platinum wire used in the anode constitutes one of the most important points in the construction of the interruptor, as has to an extent been already shown. I have been called to task by a contemporary for recommending a wire so small as 20 B.W.G. This has, in my hands, proved so successful that I continue to use it, I have never had the apparatus stop working since I adopted it, and I rarely get a broken tube. In most of the bought interruptors a larger size is used, but experience alone can teach which is the better.

An interruptor in which the length of the platinum wire exposed can be regulated at will is a great advantage, as, by taking note of what has been said of the influence of the specific gravity of the electrolyte, any size coil can be worked from any current up to 220 volts without a rheostat. An adjustable interruptor is shown in fig. 5. In this instrument the platinum wire passes through a small hole in a piece of china, or baked clay, the length being varied by the screw, A.

Fig. 6 shows a form of interruptor in which the anode is surrounded by a cylinder of lead.

It must be kept in mind that a considerable amount of gas is generated when an interruptor is at work, and, moreover, that it is given off in the proportions necessary for forming water; hence under no circumstances should a light be brought near the vessel after it has been working for any length of time, or a serious explosion may occur. It is also very desirable that, in covered interruptors, large holes should be provided for the free escape of the gases, or an explosion may occur from internal pressure.

The behaviour of Crookes tubes when worked with the interruptor is a matter of much interest. Small tubes are next to useless, as they heat very rapidly, and in many cases the vacuum is so much reduced after a few seconds working that no X rays are produced. They are not necessarily spoiled, as with the platinum contact-breaker the vacuum can soon be raised to the desired point again. I have purposely thus reduced the vacuum of several tubes I had put away as useless with a marked measure of success.

Fig. 4.

The tubes I have worked most successfully with the interruptor are large ones with a bulb of at least six inches in diameter. A medium high vacuum gives the best results, and it is an advantage to somewhat raise the vacuum of a new tube by means of the contact-breaker before

\* The coil, with platinum contact-breaker and 12-volt accumulator, gives a full 12-inch spark.

using it with the interruptor. A tube in which there is a tendency for the vacuum to increase even when the anti-cathode is raised to a red heat is the ideal one for working with the interruptor, and is likely, with care, to last for a considerable time. In some tubes, owing, no doubt, to the presence of some metal in the solder which is easily volatilised, the vacuum is reduced to such an extent as to render them next to useless immediately the current is switched on; such tubes are perfectly useless for our purpose.

In several tubes in which the anti-cathode is composed of a fairly thick piece of metal, with a thin covering only of platinum, a hole has been melted through the latter metal before any indication of its reaching the melting point was observed. As long, however, as the thicker metal support was not melted, I have noticed no great falling off in their working power. No tube in my hands will run for longer than a minute when sufficient current is passed through to enable it to give a maximum amount of X rays. The anti-cathode must be carefully watched, and the current switched off directly it assumes a full red heat. Fifteen to thirty seconds rest must be given before the current is again passed through. The having to switch on and off the current is a nuisance, which can only be avoided by a considerable alteration in the methods of manufacturing tubes.

I have noticed some curious phenomena in the working of tubes with the interruptor for which I can give no explanation. With the contact-breaker, or mercury interruptor when a tube reached so high a vacuum

Fig. 5.

Fig. 6.

that sparks refused to pass through, they either jumped or brushed over the outside of the tube. When the same thing occurs with the electrolytic interruptor, the spark evidently passes through, as is seen by a small glow near the cathode end, or a bright spot somewhere on the surface of the glass, but no X rays are produced, although no sparks are to be noticed on the outside of the tube. If, however, the tube be left working, it will suddenly be lighted up, and will continue to work until it has again rested, when the same process will have to be repeated.

When passing a large amount of current through a tube of high vacuum, a fine brush of sparks sometimes covers the whole surface of the glass. Several times when doing this I have noticed that a patch of glass about three-quarters of an inch in diameter exactly opposite the anti-cathode pole, and immediately beneath the cathode, has ceased to fluoresce, and in the brightly lighted tube appears as a black patch. From the centre of this a bright, fairly thick spark passes to the cathode terminal. On first seeing this I naturally thought that the tube was ruined, so put in resistance and allowed it to go on working. Much to my surprise, the tube worked steadily on, so I again repeated the experiment. The spark in question appeared to come through the glass; at the same time the vacuum of the tube was not reduced. The experiment appears to be fraught with danger, but I mention it in the hope of getting some explanation of the phenomenon.

In using the fluorescent screen with the interruptor I have failed to notice any marked increase in the fluorescence, although its steadiness is a great advantage. In taking radiographs, however, not only does the necessary exposure appear to be lessened by the rapidity of the interruptions, but the power of the X rays appears to be increased. If this is so, I take it that the reason why the screen does not show more is due to the fact that under both conditions the maximum amount of fluorescence is produced, and, in order to obtain better results in this direction, we must have improved screens.

The introduction of the electrolytic interruptor opens up new fields for research, and, apart from its application to X-ray work, it is likely to prove of great service to mankind.

JOHN HALL-EDWARDS, L.R.C.P., F.R.P.S.

## SOME THOUGHTS ON LANTERN-SLIDE MAKING.

[Paper read before the Photographic Society of Philadelphia.]

BEFORE entering on this theme, it is well to state that it has been necessary to use slides for illustrating the various methods of work; as such, I trust they will answer the respective subjects for which they are intended, but wish to disclaim any intention of giving a slide exhibition. Also, as the reduction method used is fully set forth by Mr. Stieglitz, in his excellent paper on slides, of September 1897, I would call your attention to this paper for any further hints on the use of a reducer.

"How to make a good slide," could easily be answered by stating that no result is to be accepted that is not as good as the best *print* it is possible to make. This may rule out "the usual thing," but that doesn't out any figure.

How is the exposure for a lantern plate usually judged? Guessed at, and generally missed—sometimes don't even know it is missed.

How is the colour given by an exposure of this kind foretold? Simply accepted as "just what we wanted."

The method here given is used by the writer, but probably many of you have methods as good or better, and it does not do to say, "This is the way," or "That way will not work," as we find good results obtained by many means which we may consider not suited to our own way of working. What is claimed for this method is: positive results, quickness in arriving at the object worked for, and economy.

The negative is developed according to the subject and the result required, and not for any relation it may bear to the slide made therefrom. Of course, it should not be very dense, either for this or any other process in general use. Negative is proofed on glossy paper, giving full details. This proof is made with lighter or darker printing, or possibly local sunning, &c., until the tonality is correct; i.e., until the lights and shadows are properly combined. Thus far, the proof is the guide for either the finished carbon or platinum print, or the slide. The lack of this tone value has been the cause of so much adverse criticism in the past on lantern slides, and the criticism has been perfectly just. We have all seen slides with about as much atmosphere as a geometrical figure, and with as beautiful tonality as the noted poster of recent times. As this careful attention to the proper tone is the key to success, you will pardon the emphasis placed upon it.

In making lantern slides, every one must admit that there is considerable waste of plates, unless the best results are not looked for. There is a great latitude in a slow plate, but at the same time there is a certain exposure that is going to give the finest results, and that exposure has little or no variation.

In exposing a plate for a negative, we may give under or over-exposure, and by careful work can get a negative on which it is not possible to tell what exposure has been given. With the positive all this is changed. We work with an unchanged developer, and make our exposure do what formerly the developer did. In other words, the exposure, always under control, is the movable factor.

Before making the slide proper, a plate is taken and four exposures made thereon, as shown, each exposure starting with a corner in the centre, and covering one-fourth of the plate. This uses all the film,  $3\frac{1}{2} \times 4$  inches, giving four exposures, with almost all of the view on each. If this seems expensive, I would state that this method has been in use for a long time, and less than half the plates are now required in comparison with the usual method, and the results are absolutely sure, both in exposure and colour.

This quadruple exposure, as you see, varies in time. This slide is a reproduction of a test plate, on which the exposures were ten, fourteen, eighteen, and twenty-two seconds. The finished slide, made after this test plate, is now shown.

It is necessary to state that the slides are made by daylight projection into the dark room, no cover being used after the rays pass through the lens. This allows free access to the plate, and these four exposures are usually made in two minutes. A thirty-nine-inch pendulum swings near the plate. No focussing is required, as every one-sixteenth of an inch is marked with exact focus for any sized image. This saves much time, and is more accurate, as the original focussing was done with a ruled plate. Where a camera is used this same quadruple exposure can be made, possibly just as easy, depending on the arrangements.

It is developed in the developer referred to further on, and fixed. To avoid change of light, the process should not be delayed, but I have experienced no trouble from this, as the whole test takes about ten minutes. The image selected should be the one on which the detail is complete, and the densest parts of negative *not* represented by clear glass, unless it is a light, or sun breaking through clouds, &c.

This perfect exposure known, the plate, of which you have just made the cover glass, is exposed, and *correctly* exposed, which is a great satisfaction. It is put into the same developer, and developed denser than required, but I have not usually found it necessary to develop as dense as Mr. Stieglitz states: i.e., until nothing can be seen through the plate. After fixing, with proof in view, the proper graduation of tone is rendered by local reduction with Farmer's solution, applied with a soft brush. (When much work is to be done or the weather is hot, the slide is first soaked in dilute formalin for a short time.)

This allows one to produce as perfect an effect as the best-known ways of

control in printing. The ferricyanide and hypo must be dilute. I wish this could be emphasised, as the reason for so much failure with this reducer is the use of a solution that will work *quickly*, and this will not answer. As the reducer has stained no slides, no mention of caution is made, except to keep it dilute. After washing, you will have, not a chance production from a negative, but a *picture*. The graduation of light in a negative is seldom perfect, although a good printer can make perfects from it, and this reduction corresponds to control in printing. As a reducer, the ammonium persulphate is probably as useful as Farmer's solution. It has been found to work remarkably well, both entirely and locally, where less contrast was desired. After reduction, and a rinse in water, the plate is flowed, as though developing a wet plate, with a strong solution of sodium sulphite. After flowing it for a moment, it is washed well. The colour appears unchanged. Then this same plate, if necessary, can be reduced locally with Farmer's solution to get any required contrast. As the least carelessness in the use of this persulphate reducer will give a flat, worthless slide, it is necessary to use fully as much care as with the ferricyanide.

The developer used is hydroquinone, and it is not necessary to give the formula for this well-known oxidiser. Eikonogen has been used, also ferrous oxalate, and for certain effects, pyro. The slide, *A Wet Day on the Promenade*, is developed with pyro, as effective for this particular subject. Mr. John A. Hodges, of London, recommends this latter developer (pyro very much restrained), but for general work it does not seem to equal hydroquinone, which appears particularly adapted for slide making.

The fixing bath is plain hypo, one to two, or double the strength of a negative fixing bath. This is done to save time in the exposure test.

After a slide has been fixed and reduced, it is well washed and dried, usually before a fan. It is better to dry it as quick as possible. Then it is placed in the lantern for testing. If the reduction is not entirely satisfactory, it can be soaked and further work done on it. All authorities seem to agree that no slide should be judged except by its projection, as only in this way than the correct tone quality be decided.

**Colour.**—The colour of the slide is of great importance. Personally, I prefer a clear, warm black, not muddy, but brilliant where brilliancy is needed. A few slides will give an idea of this colour, which colour is decided when the test-plate is made.

Although the brown, over-exposed colour is used, it would seem very often produced because the right exposure is not known. In fact, if the value of the exposure is not known, one is liable to get any old tone, but you can always tell the exact colour of your slide by the test-plate. If any one wishes this brown tone, it is easily made by much over exposure and a greatly restrained developer; or an old developer is very good for this purpose. A slide is shown giving this colour.

**Toning.**—It sometimes enhances the beauty of a slide to change the colour, but I have never known a poor, weak slide to make a good one by so doing. The usual black colour, as shown, is the most useful, and can always be obtained by correct exposure. The uranium colour is frequently of use for entire or partial toning. It is produced by taking one and a half ounces of a solution of uranium nitrate, one to thirty, adding about ten drops saturated solution of potassium ferricyanide and about ten drops acetic acid. It is not necessary to give exact proportions, as different colours are required, and weaker solution and also the time of immersion are both controlling factors. The plate will change from a very faint tinge of red, through all the various shades, also running into the browns. The speed of this toning can also be regulated by the addition of the ferricyanide. When the required colour is reached, it is washed and held to the light. With a cotton wad, soaked in weak sodium carbonate, the uranium toning is removed from all parts which are to remain untomed. After washing and drying, the slide is tested for colour in the lantern. Some slides, so toned, are shown.

If a blue colour is desired, the red uranium tone will change to this colour by immersion in ferric chloride, a weak solution being used.

Should a green colour be wanted, immerse the fixed and well-washed slide in a weak solution of oxalate of iron and ferricyanide of potassium. It turns blue in this bath, and then is put into a weak solution of chromate of potassium. When the slide is dried from this bath, it will be green.

The above will give all shades of red, brown, green, and blue, and I do not think any further colours are needed. However, additional toning by gold gives many intermediate shades.

**Special effects.**—Sometimes we wish a very dense slide without having it suffer the slightest loss in detail. It is made by exposing the reversed image on the cover glass, reducing both this and the slide to half the required density, and binding in perfect register. A slide is shown made in this manner. This is also a useful way of making a good negative from a weak one.

**Clouds.**—In using clouds, pictorially, there is nothing so necessary as having the altitude correct. The lack of this makes it very easy for any one to recognise printed-in clouds. In fact, it catches the eye before the lighting of the clouds, which, of course, must be the same as the landscape.

In using a cloud negative, the cover glass takes the image reversed. With a landscape negative, we expose film to film. With a cloud negative, if lighting is correct, we expose glass to film, or, if the lighting of

clouds is to be reversed, then film to film. The whole of the cloud negative is put on the cover glass, and the lower portion removed with Farmer's solution.

In addition to clouds, anything from another negative can be printed, reversed, on the cover glass. In the slide before you the clouds are printed on cover glass, also the ripples in the water, three negatives being used.

This was to have been a short article on slides, and it has not been possible to go into details, indeed it is not necessary. If we have some object other than topographical interest, and those who see the projected slide can be made to, and really do, feel the effect we strive to convey, then, I say, we have a picture. Tonality plays a large part in this effect of conveying impressions, and it is well to give it careful consideration in our work, for, like charity, it covers a multitude of sins.

PRESCOTT ADAMSON.

## STEREOSCOPIC PHOTOGRAPHY.

BOTH IN THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for this year and in the JOURNAL for November 11 of last year you published a sketch and description of the arrangement devised by the late Mr. Latimer Clark for taking stereoscopic pictures with a single camera and lens. Having myself taken stereoscopic pictures by this method forty years ago, but on a somewhat improved plan to that in the sketch shown by you, and having the identical contrivance by me now, perhaps the accompanying sketch and description of it—the former drawn to about half size—may interest those of your readers who are engaged in stereoscopic work at the present day.

An ordinary tripod stand carries a flat table of wood, on which the mahogany frame (fig. 1), which carries the camera, rests. The camera I used was an ordinary quarter-plate sliding body camera, through the tail-board of which were drilled two holes to receive the screws, *A* (fig. 1), which are fixed to the parallel laths, the heads of the screws being let in flush underneath (see dotted lines). The laths, *B* (fig. 1), are parallel to each other, and when the camera is moved from side to side it moves in perfectly parallel lines, and in this position or when made to converge slightly, is best adapted for taking objects at a distance; but, when

Fig. 1.

objects close at hand are to be taken, greater convergence becomes necessary. It will be seen that at the opposite end of the parallel laths screws, *B* (fig. 1), pass through them, somewhat similar to those which fasten down the camera, but with this difference, that the heads of the screws are square, with holes drilled horizontally through each and a right and left-hand thread cut in them respectively. They travel in a groove in the frame underneath and are actuated by a screw running through them with a corresponding right and left-hand thread cut on it, and by turning the milled head of which, *C* (fig. 1), the laths and camera are made to converge, or diverge, to any necessary degree. The dark slide (fig. 2) has an opening in the centre, *A*, the size of one picture, and over this opening is a sliding frame, *B*, fitted in the dark slide, which carries the plate,  $6\frac{1}{2} \times 3\frac{1}{2}$ , each end of the plate being brought over the opening as the

frame is moved from left to right (see dotted lines). The ground glass, which is detached, is ruled over with lead pencil into small squares, three-eighths or half an inch in size. To focus the object, move the camera to the extreme left (see dotted lines, fig. 1), and note carefully where any one part of the object intersects the lines of a particular square; now move the camera to the extreme right, and see if the same part of the object intersects exactly the same lines. If it does not, the camera must be moved back to the left position and the laths made to converge by turning the screw, E (fig. 1), until it is found, by moving the camera from left to right and *vice versa*, that the same object appears in the same place, or exactly intersects the same lines on the ground glass, when the camera is in both positions. This accomplished, remove the ground glass and substitute the dark slide. To take the pictures, move the camera to the extreme left and also the frame in the dark slide which carries the plate, lift the shutter and expose. Now move the camera and frame which carries the plate to the extreme right, expose, close the shutter, and the operation is over.

It will, of course, be understood that moving objects, or instantaneous work of any kind, is not within the scope of this arrangement, but the time required to take both pictures is very short, and I have taken portraits in a few seconds after the focussing has been completed. One

Fig. 2.

advantage of this arrangement is that the prints do not require to be reversed in mounting, and when viewed in the stereoscope will be found to combine and stand out in perfect relief, without causing any strain to the eyes, whereas pictures taken with a pair of lenses must be reversed, and require very careful trimming and mounting, in order to make them combine readily in the stereoscope without fatigue to the eyes. Should any of your readers be inclined to take up stereoscopic work with a single camera and lens, they will find the method I have endeavoured to describe give the best results. I have taken hundreds of stereoscopic pictures with both a single and pair of lenses, and, for perfect relief and true stereoscopic effect, the former has always pleased me best.

COLONEL.

#### A NEW ACETYLENE GAS BURNER.

ACETYLENE gas possesses so many advantages for isolated lighting that it is little wonder the industry is constantly progressing and is now on a sure foundation. One source of trouble which consumers have had with the new illuminant, says the *Scientific American*, has been that, owing to the great richness of the gas, it was not possible to provide burners which would consume more than one cubic foot of acetylene gas per hour without smoking and subsequent loss of luminosity. This difficulty has been obviated in a new acetylene burner invented by D. M. Steward, of Chattanooga, Tenn., by the grouping of any number of flames on one burner and by a new air-mixing device. Our engraving shows the construction of the burner. The pillar does not differ from those in general use. At the upper end of this pillar is fitted the head of the burner proper, which is made of lava or other similar substance. The burner stems extend from this head and diverge from each other. They are arranged in pairs, and the jet openings in each stem are adapted to direct the jet

toward that of the adjacent stem. Each stem is of cylindrical form, and is made slightly tapering, with the smaller end fitting into the openings in the head, and its larger end surmounted by a burner tip formed by an annular cup-shaped flange, D, and extension, A, in which the discharge opening is drilled. An opening, B, is drilled through the flange opposite the opening from the tube proper, C, which conveys the gas to the tip

A NEW ACETYLENE GAS BURNER.

(see fig. 2). Opening, B, in the flange is of larger diameter than that in the centre wall of the burner. This flange provides an air space between the extension, A, which terminates the end of the gas tube, C, and the interior of the flange, so that, as the gas is discharged from the opening, it will suck the air into the air space, and so provide for uniform admixture of the air with the gas discharged through the aperture in the flange. The air-mixing device is a unique feature of the burner, and is an improvement on all previous burners, the old method being to surround the jet of gas with a number of small inlets or holes for air. In the new burner the cup-shaped cavity provides a sufficient amount of air, and keeps the burner cooler than with any other known construction.

The tips are so arranged that the two jets are directed toward the jet from the adjacent tip, and inwardly in an oblique position. The jets so discharged from each tip commingle with the jets discharged from the adjacent tip on each side so as to form flat flames. The head being located between the pillar and the burner stems, the pillar is kept from becoming heated. The burners are made by the State Line Talc Company, Chattanooga, Tenn.

#### NEWS AND NOTES.

WRITING on the subject of a reproduction of a photograph of ribbon lightning in a recent issue, the *Scientific American* says: "An experienced photographer of lightning flashes informs us that this photograph is an excellent example of its kind, and states that the theory is that the lightning, in its passage through the air, is driven by the wind so as to flatten it out, giving it the ribbon effect. This may occur oftener than we are aware of, because, if the wind was driving the lightning toward or from the camera, the effect could not be observed. If, however, the wind blows across the field of view, then an opportunity is afforded for getting a picture of this curious kind of a flash. It is probable the study of photographs of lightning flashes may become as interesting as those on the subject of astronomy. Certainly some remarkable effects can be obtained if the proper advance arrangements are made."

ALL kinds of schemes are adopted on the Continent to outwit the surgeons who examine conscripts as to their availability for military service, and the Röntgen rays have unmasked such frauds. Some time ago a soldier in a military hospital claimed to have been bitten by a horse. A photograph of the finger was obtained, and five needles were discovered in it. The next day another photograph was taken, and it was found that the soldier had removed one of the needles. The

surgeon took out the remaining needles. The soldier had injured himself in order to obtain relief from irksome military service.

On the subject of apparent dark lightning flashes Dr. W. J. S. Lockyer writes to *Nature*: "On the evening of the 5th of the present month we were visited by a severe thunderstorm, which passed practically over this place. The lightning was very vivid, and at times occurred at intervals of only a few seconds. In order to photograph some of the flashes, I placed a camera on my window sill and exposed four films for consecutive periods of fifteen minutes each. During the exposures I was observing the sky, and repeatedly found that after nearly each bright flash I could see distinctly a *reversed image* of each flash in *any part of the sky* to which I turned my head. These apparent dark flashes, or, rather, the images on my retina, lasted for sometimes five to ten seconds. At the time I wondered whether dark flashes had ever been noticed before, and thought that this phenomenon was not uncommonly observed; but, seeing Lord Kelvin's letter in your issue of August 10, I send this note in case it may prove of interest."

A Lyons chemist has invented an acetylene lamp in which the gas is produced without water coming into actual contact with the carbide. The carbide is contained in a porous vessel, and the water in an outer vessel, and the humid atmosphere inside the carbide container, due to moisture passing through the porous walls, acts upon the carbide to generate the gas. The method is particularly applicable for bicycle and carriage lamps.

### SOME DRAWBACKS TO THE USE OF ACETYLENE.

[From the *Chemical News*.]

WHILE coal gas has had to struggle for a whole century before becoming the almost universal lighting agent, its rival, acetylene, has already—after only a short time—achieved a certain success. Of course, acetylene is not a newly discovered body, but it is only since the economic production of carbide of calcium that it has become practicable as a lighting agent.

Theoretically the production of acetylene is a very simple matter, but such is not the case practically.

Carbide of calcium, as is well known, is a black, crystalline, very hard material, not decomposed by heat, but easily decomposed by water into acetylene and lime. It has a density of 2.2, and it is not soluble either in petroleum or in benzene.

Concentrated acids have no action on it.

Acetylene consists of a colourless gas, with a penetrating odour of garlic. Its density is 0.1; 1 litre of acetylene weighs 1.16 grammes. It is easily soluble in water, and can be liquefied at 0° under a pressure of 48 atmospheres. In this state it is very explosive. It burns with a white flame, without a dark cone; the temperature of this flame is lower than that of coal gas.

Unfortunately, lighting by acetylene still presents numerous difficulties, to which I am desirous of calling the attention of specialists and others, now that I have had the opportunity of examining the installation which supplies the town of Veszprim in Hungary.

Let us first consider the carbide, the source of all the trouble. This body is never pure, but always contains at least twenty per cent. of impurities. Theoretically, 64 parts by weight of carbide should give 26 parts by weight of acetylene—that is to say, that 1000 grammes of carbide ought to produce 406.25 grammes of acetylene; and, as 1 litre of this gas weighs 1.16 grammes, we ought to get 350 litres. But the Continental factories will not guarantee a return of more than 300 litres, and practical experience shows that we can hardly depend on more than 280 to 290 litres. It is true that the estimation of the return is not free from causes of error, inasmuch as during the weighing the carbide absorbs a certain amount of moisture from the atmosphere; this causes a loss of acetylene. But the small errors which result, when calculated on 1000 grammes of material, are multiplied in proportion. We are obliged to work with small quantities, seeing that only 100 grammes of material give off 30 litres of gas, and it is difficult to arrange graduated gas-holders to store such large quantities. Further, the carbide is so little homogeneous that several samples must be tested and examined in order to obtain a mean value. If, on the other hand, we only take 10 grammes, the error resulting from the disengagement of acetylene in the air will be multiplied 100 times if the results are calculated, as they should be, on 1000 grammes. I have examined the manner in which the carbide behaves in the presence of acids, and I found that concentrated sulphuric acid has no action on this body; but, no matter how little water the acid may contain, bubbles of gas are formed until the whole of the water is consumed. This property of the carbide of not being attacked by concentrated sulphuric acid enables us to estimate its producing power of acetylene. I have made several experiments in this direction, and the results obtained were fairly correct and concordant.

I must here again mention that the carbide contains sulphur, phosphorus, and nitrogen, from which it results that the acetylene will be

contaminated with sulphuretted hydrogen, phosphoretted hydrogen, and ammonia. The acetylene must therefore be purified to the same extent as is coal gas, for fear that its use in closed places might cause serious accidents.

But the greatest drawback of all is that acetylene burns with a smoky flame. Certainly the flame does not smoke at first, but after 200 or 300 hours smoke begins to be formed. This is caused by the burners attaining a temperature higher than that of the decomposition of acetylene, and thus the gas is decomposed into carbon and hydrogen.

I have also noticed a very curious phenomenon in the gas pipes; I there found a deposit of finely divided carbon like soot. I also found a very remarkable liquid condensation, consisting of carbides of hydrogen. These bodies are also formed in the generators, whence the necessity of using siphons. We thus see that it is quite erroneous to imagine that acetylene does not require purifying.

There is still another inconvenience resulting from impurities contained in acetylene. It is by no means uncommon to see, in a closed place, a sort of fog fill the room after a longer or shorter interval. What is the cause of this phenomenon? The acetylene is decomposed in the burner, the carbon is deposited while the hydrogen burns, giving rise to the formation of watery vapour; and it is this, in conjunction with the ammonia, the sulphuretted hydrogen, and the phosphoretted hydrogen, which produces the fog, causing headache and nausea.

PROF. J. VÉRTÈS.

### PHOTO-MECHANICAL LANTERN SLIDES.

PROFESSOR ERREERA, of the Brussels University, has published some improvements in the production of slides for optical lanterns. In carrying out his invention, he prints the image with transparent ink by any suitable process of photographic reproduction on a transparent support.

Such support may be celluloid, gelatine, collodion, mica, specially prepared glass, or any other transparent and suitable substance.

In this way the lantern slides are mechanically produced either in black or single colours, or in a series of colours, such as the natural colours of the object, which are obtained by successive printings in colours on one and the same support by means of separate blocks or plates, each obtained from a different negative of the same object, the negatives being respectively made after interposing a coloured or intercepting screen.

The preparation of lantern slides in the case where it is desired to reproduce the natural colours of objects has heretofore usually been a long and costly process, though various methods are employed for producing them, among which are those suggested by Lippman, Maxwell, Cros, Ducos du Hauron, Richard, and Ives.

The method employed of printing the required number of transparent positives on the same transparent support is rendered possible by the employment of a support which is at the same time transparent and sufficiently flexible to enable the mechanical printing to be effected.

As an illustration of one manner of producing a slide in natural colours, he gives the following:—

A first negative is obtained on a plate or support sensitive to yellow and green rays, after interposing a colourless solution absorbing the ultra-violet rays (for example, a solution of alkaline nitrate) and a yellow intercepting screen (for example, a solution of ammonium picrate, or a gelatine film stained with ammonium picrate). A second negative is obtained on an ordinary plate or support (which is sufficiently sensitive to blue and violet rays) after interposing the aforesaid colourless solution and a violet intercepting screen (the latter, however, not being absolutely necessary). A third negative is obtained on a plate sensitive to orange and red rays, after interposing the above colourless solution and an orange-red intercepting screen (for example, a solution of erythrosine and aurantia, or two gelatine films, respectively stained with eosine and aurantia).

These three negatives are used for obtaining in some well-known way three blocks or plates either by photo-collography (bichromate-gelatine process), or in phototype-engraving, with the help of a net or mesh ("phototypographe").

From the plate of negative No. 1 may be obtained a crimson print, from the plate of negative No. 2 a yellow print, and from the plate of negative No. 3 a greenish-blue print, all three being made with transparent inks on a single transparent, smooth, and flexible support.

The best support appears to be celluloid or gelatine, though it is possible also to succeed with collodion, mica, or specially prepared glass.

In *Astronomische Nachrichten*, 3565, Sir William Huggins, in a short note, preliminary to a fuller account to appear in his book of photographs of star spectra promised for early publication, announces that he is able to confirm Mr. McClean's statement as to the presence of oxygen in stars characterised by the presence of strong helium lines. In the ultra-violet about ten lines, considered to belong to oxygen, appear to coincide with lines in various helium stars, though the relative intensities of the oxygen lines, as observed in the laboratory, do not exactly agree with their relative intensities in the stars.

## LANTERN NOTES AND NEWS.

MM. BERTHELOT and DELÉPINE have experimented on the compounds of acetylene with silver, silver nitrate, sulphate, chloride, and iodide. When heated in a vacuum, dry silver acetylide,  $\text{Ag}_2\text{C}_2$ , detonates, with formation of a reddish flame. This flame is scarcely to be expected, since the products of the explosion are solids, silver and carbon. However, investigation of this matter leads to the conclusion that the temperature of the reaction is high enough to volatilise the carbon, and that the flame is gaseous carbon at a very high temperature, probably approaching  $4000^\circ\text{C}$ .

THE big exposition at Niagara Falls, says *Electricity*, will be the occasion of what will, doubtless, be a most brilliant and startling illumination. The idea is to erect a series of tall towers on both the American and Canadian sides of the river. On the top of these lofty spires huge electric searchlights will be placed, in such manner that they may be played on any part of the Falls. The imagination may picture the dazzling effect that will be produced when a score of those powerful instruments of illumination are brought to bear upon the rushing waters as they tumble irresistibly over the rocky ledge into the depths beneath. A constant change of colours will be used in the manipulation of the searchlights, so that now the Falls will be like molten silver, again a flood of crimson, again as green as old ocean itself, and so on through the whole gamut of colours of the painter's palette. The astonishing effect will be still further heightened by the use of electric arc lights in the Cave of the Winds, which will give to the water as it falls in front of it a weird, phosphorescent glow. The power of this record-making illumination will be all within easy reach, as Niagara will itself be made to do all the necessary work.

"OMEGA" writes to the *Daily Chronicle* to say that the evil of the objectionable mutoscope is not confined to the metropolis and seaside. He travels about the country and finds the same scandal everywhere. "In a Midland city which is renowned for the large number of young people that compose its population and are employed within its borders, I made a personal investigation of one of these exhibitions. A shop in a prominent street had been hired for the purpose. The admission was free, but a penny was charged for

each view. I frankly admit that some of the pictures were refined and beautiful, but these were interspersed with others of a low nature. Those which were not flagrantly obscene were suggestive of evil and calculated to engender foul imaginations and impure thoughts. Around one of the most impure of these exhibits I watched a group of girls, ranging in age from ten to fifteen years. An outer circle was formed by youths and men, who, with leering eyes and base language, supplemented any vicious suggestions these pictures had already made."

ACCORDING to *Comptes Rendus*, MM. Berthelot and Le Chatelier have studied the velocity of propagation of the detonation of acetylene under different pressures and with other varying conditions. The gas was contained in horizontal glass tubes about one metre long and of diameter between two and six millimetres. It was introduced under pressures varying between five and thirty-six atmospheres, and was found to contain ninety-eight per cent. of acetylene. The gas was fired electrically, a small piece of fulminate being used, and the registration of the phenomena was made by the photographic method, which method gives an exact record of all the phases—at least, in so far as the gas remains luminous.

THE following are next week's Lantern fixtures at the Royal Photographic Society's Exhibition: Saturday, October 7, "A Trip to Paris, *via* Newhaven, Dieppe, and Rouen," by Algernon Brooker. Monday, October 9, "Zoological and Other Animal Studies," by Henry Sandiland, J.P. Wednesday, October 11, "Beauties Old and New in the French Riviera," by S. J. Beckett. Saturday, October 14, "Mountaineering within the Arctic Circle," by Mrs. Main.

AN additional attraction was given to the Royal Photographic Exhibition on Wednesday evening, September 27, by a lecture on the Royal Palaces of England and Scotland. The lecturer was Mr. Horatio Nelson King. The series included several new photographs taken at Osborne by the Queen's command last August. The private and State apartments in the several palaces were shown on some 200 slides. From the educational, no less than the artistic, point of view the lecture was charmingly interesting.

MR. BIRT ACRES announces the imminent introduction of a new light for lantern purposes; it is described as safe, non-explosive, and portable. Affording an illuminating power of from 600 to 1000 candles, it requires neither cylinders nor generators, and gives off practically no heat.

THE following is Messrs. Newton's list of new slides for the season 1899-1900: Wireless Telegraphy. Birds and Animals, by R. B. Lodge. Spiders and Insects and Butterflies. Canterbury—

the City and Cathedral. China. Burma. Malay Archipelago. National and Tate Gallery. Belgium. Elements of Agriculture—Cattle and Wheat. St. Paul's Cathedral. The Thames. Flower Studies. Australia—Up Country. Meteorology. Astronomical Work in the Solar Physics Observatory. Lang's Fairy Tales. Alice through the Looking-glass. Stations of the Cross from Wood Carvings. Chinese Illustrations of Bible Stories, &c.

### LANTERN MEMS.

"WHERE are the lantern slides?" This question was asked more than once by visitors to the Exhibition of the Royal Photographic Society at 5A, Pall Mall, and certainly this particular class of photography, which, as an exhibit, has been getting smaller by degrees and beautifully less of late years, has this year reached a minimum that can almost be counted on the fingers of both hands. Why is this? One explanation offered was that no medal for this class of subject had been awarded for several years, and therefore it was probably answerable for the want of interest or the lack of exhibitors. Cannot the Council of the Royal Photographic Society reconsider this matter, and try for next year's annual to get a really representative show of transparencies at the new rooms?

It might also be worth while to invite trade exhibits of new subjects, and provide suitable screens or frames where the photographs can be properly shown without having to pass through curtains into a curious little "cubby house," and dodge steps that lead up to the operating sanctum. Only a few of the visitors who are strangers to the Gallery understand that lantern transparencies can be seen on passing into this place. If table room was provided, and hanging or other electric lamps arranged so as to give a brilliant reflected light, we should have our large (and small) slide producers sending the pick of their new subjects, but the fee for space must not be prohibitory. These slides would be attractive and allow of a closer examination of those subjects which specially appealed to one at the time of their exhibition on the screen, for each frame should in turn be emptied during the season, and passed through the lantern and replaced in the frame the next day at latest.

If these transparencies were mounted, say, six in a carrier, they could be quickly taken out of the show frame before the Exhibition, and very quickly replaced after the lantern projections were finished, and members and visitors from the country who could not perhaps make a second visit could judge so much better what to aim at in their own work in future, for it is a truism that many slides that look well in the hand are disappointing on the screen, and *vice versa*. While on the subject of transparencies I should like to mention the stereoscope, and that this deserves more encouragement and better treatment. I suggest that a really first-class instrument or several should be available, and so placed that they have a separate illuminator, in order that the beautiful stereoscopic effects can be appreciated. With these remarks and hints for a little more "stage management," I pass on to a subject for which I have nothing but praise.

The lantern display on Saturday evening was in every way satisfactory, a clear and well-defined picture of a series of photographs of a "Visit to Ireland," that were not only beautiful but interesting to a degree. They were lantern transparencies made from negatives taken by the members of the South London Photographic Society, and arranged by Mr. C. H. Oakden. I was personally more interested from the fact of having this year and last visited some of the places depicted, and could not help being charmed by the lovely light and shade shown in the pictures of lake scenery, waterfalls, bracken, vegetation, and landscapes, while the short description and humorous references prevented anything like monotony supervening. Until I knew it was collective work of members, I said, if a "one man" show, the photographer must have been indefatigable, for so many,

different points of view were shown of interesting places, relics, &c., each having more or less a charm of its own.

I WAS in hopes of seeing some good examples of chromo-photography for the lantern, but had only the satisfaction of viewing two or three specimens of trichromate printing by Mr. E. Sanger Shepherd. An apparatus for showing photographs in colour could not be tested, because no suitable light was available in the evening for the purpose. A very useful daylight dark slide was exhibited at the table on behalf of Messrs. Mackenzie & Co., of Glasgow, and, if it and the envelope containing the sensitised plate are really light-tight, it will be an enormous advantage to travellers who prefer to use plates, and do not care to develop *en route*, or who cannot have resort to the dark room, or prefer not to carry a number of ordinary double dark slides. With this arrangement, if proved to be reliable, a saving in bulk will be effected, and one special dark slide sufficient for any number of plates to be exposed as required. It often happens that, after the last plate that one has in the double dark slide has been exposed, a particularly "pretty bit" or interesting subject is seen, and with the plates in envelopes a few extra for emergency use can be taken without inconvenience.

I HAD hoped to see some novelties in optical lanterns, but beside the Biokam, for miniature animated photographic projections, there was little else. Next year, perhaps, a larger space can be devoted to apparatus for projection, and the inventors or manufacturers induced to send up-to-date instruments, so as to make the section worthy of the Society's Exhibition. When one knows that Messrs. Swift, Newton, Steward, Butcher, Hughes, and others have been working on photo-micrographic apparatus, projection microscopes, optical lanterns, and special illuminants, the question arises, "Why are they not exhibiting?"

G. R. BAKER.

### AN ANALYSIS OF LANTERN PLATES.

PROFESSOR VALENTA gives an analysis of several kinds of lantern or transparency plates in the *Photographische Correspondenz*. The names are suppressed, and Roman figures substituted for obvious reasons, but certain English makes, which enjoy considerable reputation in Germany, and some American are included. For the analysis the plates were weighed before and after boiling in dilute nitric acid, to ascertain by the difference in weight the quantity of emulsion on each plate. The solution obtained was then boiled until the silver salts precipitated, after being allowed to stand for a short time. The salts were collected by filtration, washed with hot water, dried, and weighed. The total of chloride plus bromide was thus ascertained. A portion was weighed off, treated with zinc filings and dilute sulphuric acid, and the quantity of reduced silver ascertained. This multiplied by 1.3287 gave the equivalent of chloride. By deducting the quantity of chloride from the mixture of chloride and bromide, and multiplying the difference by 1.798, the quantity of bromine present in the mixture of chloride and bromide was determined. The corresponding quantity of silver bromide was then calculated. The following results were obtained:—

Plate Number.	Colour after long exposure to light.	Thickness of film in mm.	Grammes of emulsion per 100 sq. cm.	Grammes of gelatine per 100 sq. cm.	Grammes of silver haloid per 100 sq. cm.	Proportions of haloids.	
						Bromide.	Chloride.
I.	Grey violet (slowly)...	0.04	0.396	0.324	0.062	85	15
II.	Grey (slowly) .....	0.04	0.418	0.365	0.053	100	—
III.	Violet .....	0.028	0.244	0.194	0.050	50	50
IV.	Grey (slowly).....	0.030	0.285	0.176	0.109	100	—
V.	Violet .....	0.028	0.286	0.190	0.090	36	64
VI.	Grey green (slowly) ...	0.036	0.229	0.158	0.071	90	10
VII.	Violet (rapidly) .....	—	—	—	—	10	90
VIII.	Intense violet (rapidly)	0.044	0.328	0.230	0.098	10	90
IX.	Reddish violet (rapidly)	0.036	0.174	0.115	0.059	20	80
X.	Violet .....	0.024	0.211	0.150	0.061	58	42
XI.	Violet (slowly) .....	—	—	—	—	70	30

## LANTERN-PLATE EMULSIONS.

In the article previously quoted, Professor Valenta gives the following formula, which he recommends. For plates suitable for normal negatives:—

A.	
Water .....	400 grammes.
Ammonium bromide .....	15.2 "
" chloride .....	1.5 "
Nitric acid.....	6 drops.
Gelatine .....	50 grammes.

B.	
Water .....	400 grammes.
Silver nitrate .....	30 "

For flat negatives, or for obtaining normal prints from flat negatives by reproducing the negative one or more times:—

A.	
Water .....	400 grammes.
Ammonium bromide .....	1.7 gramme.
" chloride .....	9.0 grammes.
Nitric acid .....	6 drops.
Gelatine .....	50 grammes.

B.	
Water .....	400 grammes.
Silver nitrate .....	30 "

Swallow the gelatine in the water, melt at 50° to 60° C. in a water bath, add the bromide, chloride, and nitric acid. Raise solution B to the same temperature, and add it in small quantities to solution A, well shaking the bottle in the intervals. Keep the emulsion warm for an hour, pour it into a dish, and, when set, break it up and wash it. After remelting, it is ready for coating the plates.

For the emulsion containing most bromide, use the following metal developer:—

A.	
Metal .....	10 grammes.
Water .....	1000 "
Sulphite of soda .....	100 "

B.	
Carbonate of soda (crystal) .....	100 grammes.
Water .....	1000 "

Use equal parts A and B.

For the plate containing most chloride use hydroquinone developer:—

Hydroquinone .....	3 grammes.
Sulphite of soda .....	100 "
Water .....	1000 "
Soda .....	200 "
Carbonate of potash.....	100 "
Bromide of potassium .....	3 "

This yields warm brownish-black tones.

The following bath for toning chloride plates will be found a good one:—

Chloride of gold.....	0.5 gramme.
Sulphocyanide of ammonium.....	8 to 10 grammes.
Water .....	1000 c. c.

## SPIRIT PHOTOGRAPHY.

DESCRIPTION in spirit photography has become a fine art. Many so-called "spirit pictures" have been taken upon plates that have already been exposed. When these plates are developed, the several faces, of course, are brought out. These prepared plates are held in stock by dealers in photographers' supplies, says *The Banner of Light*, and sold to all who send special orders for them. It is now well known that a certain symbol in the order for plates indicates that "doctored" plates are desired. In some cases, men and women who are perfectly honest with themselves are obtaining what they claim to be spirit pictures. They order their plates themselves, and take pictures of themselves by means of a mechanical device, develop the plate alone, and find faces side by side with their own on the plates. This would seem to justify them in believing the pictures to be likenesses of disembodied spirits. If they would reflect a little, they would not be so certain.

Pretended mediums for spirit photography know of the experiments of these parties to whom we refer. They notify the dealers in photographic

stock of the fact, and these dealers send them the prepared plates. The pictures are taken, and the amateur photographer becomes convinced of the truth of spirit photography because they alone were implicated in the experiment. The fact is they have been deceived in their plates through the efforts of some faker who wished to add to his own income, and to maintain his influence over the parties whom he is instrumental in deceiving. It is often done, and many reputable people are thereby victimised.

Occasionally a few of the prepared plates are slipped into the boxes ordered by regular photographers. They are not spiritualists, nor are the majority of their patrons. Every one is greatly surprised, therefore, to find half-dozen faces upon the proof of a certain plate. When the fact of these specially prepared plates is made known, the source of the phenomenon is easily determined. The unsuspecting person, however, does not stop to think of possible collusion in the case, and accepts the result as evidence of supernormal power.

## OPEN-AIR LANTERN DISPLAYS.

THE ardent lanternist, with the shortening days, will be furnishing up his apparatus, and, no doubt, feeling eager for an opportunity to have a lantern display. With many of them, no doubt, the idea prevails that, until the winter evenings set in, they need not look for any great hopes of opportunities to try their lanterns. There is, however, a most delightful field for lantern work during the early autumn evenings, for during the month of August and September open-air displays can be given that yield far and away beyond the pleasure experienced in working in some stuffy or badly ventilated room or hall during winter nights.

What better position for a lantern exhibition could be desired than that of a nice quiet garden, the atmosphere of which is laden with a wealth of perfume from choice flowers? And yet how seldom do we hear of the optical lantern being brought into requisition at such functions as garden parties, &c.

The idea, no doubt, prevails that the wind is almost certain to give trouble, but how many evenings are there when the air is perfectly still, and it is quite a luxury to sit in the open air for several hours after sunset, enjoying a pipe of peace or a fragrant weed.

During the present autumn it has been the writer's privilege to witness several lantern garden displays, all of which were more than appreciated by both old and young. Of course there are nights when any such displays would be out of the question, but there is at some season of the year always a spell of settled weather when an ardent lanternist can, with perfect confidence, rely upon suitable atmospheric conditions, and carry out a well-arranged programme of this description, feeling certain that any invitations he may favour his friends with will not be damped by adverse weather conditions.

The screen need not be other than that ordinarily used indoors, and, when stretched upon its frame, can always be utilised in some suitable part of a garden, one plan being to suspend the frame from the branches of trees, or, if the spot selected be against a house, a line let down from a window, and made fast to each of the top corners of the frame, will enable the same to be placed in almost any position.

As to the best light to employ, I have no hesitation in saying such is found in a good mixing jet, the power of which will depend upon the size of disc desired. In open-air working sizes of everything appear smaller than indoors, but any disc from twelve feet upwards will be found quite satisfactory, and a good single lantern, furnished with a modern dissolving carrier, will suit admirably.

If a twelve or fourteen-foot disc is selected, there will be no need to press the jets unduly, and, even with the slight amount of natural light which always remains during a summer or autumn evening, a very brightly lighted picture can be obtained.

The best hour to give entertainments of this description will be found to be about an hour after the sun has set, so that towards the end of August, when the sun sets about half-past seven, the lamp may quite well be brought into requisition shortly after eight o'clock, and this does not make the function unduly late, although it will rarely, if ever, be found that one's friends weary by too long a display.

An abundance of slides should be provided, for where there is no lecturing, or but a scanty description of the views thrown upon the screen, it will be found that even one hundred slides don't take a long time to slip through the lantern, and three times this number will often be required to satisfy an appreciative audience as they sip their coffee and smoke their pipes.

One of the most effective class of slides for open-air displays will be found in statuary subjects, and, when these have the background blocked out so as to show against a black ground, the effect is very striking. A large stock of good comic slides should also be provided; it is quite surprising how such good old stuff as the "Elephant and Nigger," or the "Mad Umbrella," yields so much delight to all and sundry. Of course there are comic slides that, unfortunately, must be deemed vulgar;

these are best left out; but still we have thousands to select from that are quite beyond suspicion, and a few mechanical slides, such as the "Red Man," always convulse the younger portion of the audience.

Coloured slides always look well when displayed in the open air, and perhaps there is nothing finer in this respect than flower studies, of which, during recent years, some excellent examples have been placed upon the market.

Animal studies also come out bold and striking on the screen, much more so than landscapes, so that it is well to spend a little time in selecting the best class of subjects to show.

If a blunial or triple is employed, then, of course, an additional charm is lent to such displays by including many effects, slides that, with proper care in registering, yield, perhaps, one of the most delightful entertainments imaginable. The introduction of the cinematograph has, no doubt, done much to throw dissolving effects by means of double or triple projection completely in the background, but there are those whose opinion is worth considering who prophesy that there will be a reaction before long in favour of the good old dissolving effects so popular a few years ago.

The belief is gaining ground that the cinematograph fosters vulgarity; this, of course, need not be. Yet, unfortunately, the music-hall displays of prize fights, and other similar views, have not tended to raise it in the estimation of the better classes.

In open-air lantern displays there is a field for much enjoyment during the summer and early autumn nights, which those who once experience are sure to wish repeated.

A. T. NEWTON.

### ASTRONOMICAL PHOTOGRAPHY.

At the Annual Meeting of the Oxford Camera Club, on Monday, September 25, the President (Sir William Herschel) said that he proposed to say a few words about the wonderful astronomical researches of Mr. Maclean, first begun in this country, and afterwards continued at the Cape of Good Hope. His work, undoubtedly, represented the greatest advance in astronomy during the last twenty-five years. To enable them to understand in some small degree the magnitude of his efforts, he would tell them that he had taken by means of photography the spectra of 276 stars in both hemispheres. In fact, all the stars of the first, second, third, and third and a half magnitude and, of course, those above the first. He had afterwards classified these stars by means of their spectra, and it was out of that work that his great discovery came, which made in future the Milky Way the basis of our study of the stellar universe. He did not propose to suggest what the Milky Way really was, but the large stars in it had now been shown to be, very near akin to various gaseous nebulae in other parts of the sky. He would throw on the screen a photograph of the nebula in Orion. As seen through a good telescope this was one of the most enchanting sights to be observed in the whole sky, but the photograph, through that peculiar and wonderful property of light known as actinic, showed a great deal that was not seen by the human eye. It was these nebulae that Maclean took for his first type, as he would explain later on. The photograph of the nebulae in Andromeda had peculiar interest, in that it disclosed the fact that it appeared to be a solar system in the first stage of formation, while all the human eye was able to discover through a telescope was that it was a mass of nebulous matter, of oblong form. The nebula in Orion had apparently reached a further stage of development, having a more perfect shape. Before the time of photography astronomers knew it as a ring of nebulous matter, but a photograph at once disclosed the fact that there was a mass of light-giving matter in the centre of the ring, indicating a solar system in course of formation, the gaseous matter gradually approaching toward the centre and consolidating to form a planet. Again, until the Pleiades were photographed, no one suspected that these stars were surrounded with nebulous matter, yet such proved to be the case, giving rise to the supposition that the Pleiades were planets in the last stage of formation. If this theory of the formation of stars were true, then it was possible to speak of the age of a star. Now, Maclean approached this subject from quite a different point of view, and proceeded to examine the spectra of the stars, to see if by that means he could classify them. Again photography had to be brought into requisition, for it was quite impossible to examine and measure the spectrum of a star with the human eye with sufficient accuracy. The spectrum of a pin point of light, such as would be given by a star in a properly adjusted moving telescope, produced such a fine spectrum line as to be almost useless for measuring purposes, but, if the spectrum were taken in a stationary telescope, a number of the fine spectrum lines would be obtained close together, which would form a band of spectra, which could be easily read and examined. There were, of course, other ways of obtaining the spectra of the stars, but there were none so simple or so free from error as this, and it was now generally adopted.

On looking at the spectra of the 276 stars, the most remarkable thing was that many were so alike, for, considering the number of elements, the natural supposition would be that there would be great variety. He would first call their attention to those stars which showed the lines denoting hydrogen in a high state of incandescence covered by an outer film of the gas in a cooler condition. In these spectra were also to be

observed the distinctive line of gaseous helium, which gained its name from the fact that its presence was discovered in our sun before it was found on our own planet. Now, the spectrum of the Orion nebula also showed these special lines of hydrogen and helium, so that set of stars were called the Orion or Helium stars, and they numbered no less than 88. On looking out the position of these stars in the sky, it was found that 70 of them were actually in the Milky Way, while the other 18 approximated to it. This peculiar fact could not be due to chance, so an explanation had to be sought. Now, it was estimated that the breadth of the Milky Way was such that for the light of a star on one edge to reach a star on the other edge would take 245 years. If, then, we were in the centre of the Milky Way, it would be quite possible that some of the stars comprising it would appear to us to be in a different part of the heavens, though they were really in the same big plane. In this way the apparent different position of the odd 18 stars could be accounted for. It was this theory, suggested by the peculiar position of the helium stars, which had altered our old ideas of the sky, and compelled us to believe that we were part of the Milky Way. Going back to the classification of the stars by means of their spectra, the next group were those in which calcium appeared and helium vanished. These were looked upon as older in age, because of the absence of the helium lines, and they were called the Sirius stars, because of their resemblance to the spectrum of Sirius. They were not so numerous as the first group. The next class approximated more nearly to the spectrum of our sun, and both of these last groups were distributed pretty evenly over the whole sky. It was for the wonderful discoveries he had described that the gold medal of the Royal Astronomical Society had lately been awarded to Mr. Maclean with acclamation. He hoped that his brief survey of the subject would in the future give the members of the Oxford Camera Club more interest in that great adornment of the sky, the Milky Way. He could not conclude without adding one word about that wonderful phenomenon, light, which contained two such incomprehensible attributes. The first was its faithfulness, the accuracy with which it carries its message from the far off stars to our own planet. The second was its actinic, which, in connexion with photography, enabled it to reveal its message to human reading. He would earnestly ask photographers not to look on light as their slave, but to remember that they were rather the servants of light, and as such should receive its message, and do their best to make it a source of usefulness and pleasure to mankind.

### LANTERN SLIDES BY CONTACT.

[Paper read before the North Middlesex Photographic Society.]

THE method of making lantern slides by contact from the negative, which I am down to demonstrate this evening, is very simple, and, if the directions which accompany each box of plates are carefully followed, you cannot go far wrong. Still, very often actually seeing the operation performed is of more use than instructions on paper.

Cleanliness is a *sine-quâ-non*. The negative must be well dusted, and so must the lantern plate. Pinholes and dust marks will spoil any slide, and are more noticeable in the slide than in the negative. Slides are not often made by contact from other than quarter-plate negatives, but occasionally a piece out of a larger negative may be obtained that will make a satisfactory slide.

Choose a negative that will give a good print, either in P.O.P. or platinum. A too thin one will not give a satisfactory slide unless by dodging, neither will a harsh one. With regard to exposing, if you are using any of the commercial plates for black tones, you can either expose to a gas jet or use magnesium ribbon. Ilford special will require about twenty seconds twelve inches away from a gas jet, or one inch of magnesium burnt at six feet distance. Thomas's will require about three times as much, Cadett about twice, Barnet about half, Paget slow the same. The speed of the various plates varies considerably, as you see, and it is advisable to stick to one kind (they are all good), and you will spoil much fewer than if you change from one brand to another. As to the developer, if you make up from the formula given, you will get good results, but a pyro developer, preserved with sulphite or metabisulphite, will give as good with most, if not all, the plates. It tends to give a warm black tone, as opposed to metol-amidol or hydroquinone, which give a grey-black tone with short exposures.

Warm tones may be obtained by simply increasing the bromide in the developer, and giving a correspondingly longer exposure. Some plates are more amenable to the action of KBr than others.

Fix in clean hypo, four ounces to pint, and, if veiled at all, immerse in a weak Howard Farmer's reducer until cleared.

I will just touch on the method of putting in clouds. Personally I always have them on another plate, and use that as a cover glass. Care must be taken, if this method is used, that the clouds are the same tone as the view. One method is to expose a plate behind a cloud negative, shielding the lower portion, develop and fix. Place the view and the cloud slide glass to glass, and eat away the portion of the sky where it overlaps the landscape with a strong reducer (Belitzki's or Howard Farmer's), using a tuft of cotton-wool as a mop. The action of the reducer vignettes off the cloud portion, and it must be allowed to slightly overlap the landscape. (Example shown.)

When the slides are washed and dried, place them film to film; no junction will be visible. Another method, if you use film negatives, is to place in the printing frame a clean sheet of glass, then the slide to which it is desired to add a sky, gelatine side up; the film sky negative is placed above this, and lastly the lantern plate. Great care must be taken that the lantern plate is exactly above the slide containing the view, otherwise they will not coincide when it comes to binding them up. (Example shown.) After development, dissolve away the lower portion below the horizon, which may have printed through the landscape, with Howard Farmer's reducer.

(This method has not much to recommend it, owing to the difficulty of registration, and is only suitable when there is a strong horizon.)

Appended is a table of exposures and developers used for getting warm tones by increasing the exposure and potassium bromide in developer, the slides being shown to the meeting:—

#### ILFORD LANTERN PLATES.

##### Negative Brilliant.

###### No. I.

Exposure, one inch magnesium; distance, six feet.

##### Developer.

Pyro (to ounce) .....	2 grains.
KBr (to ounce) .....	1 grain.
Carbonate of soda (to ounce) ..	22 grains.
Sulphite of soda (to ounce) ..	22 "

Time, about three and a half minutes; temperature, 70° F.; result, black.

###### No. 2.

Exposure, one inch magnesium; distance, three feet.

##### Developer.

Pyro (to ounce) .....	2 grains.
KBr (to ounce) .....	4 "
Carbonate of soda (to ounce) ..	22 "
Sulphite of soda (to ounce) ..	22 "

Time, about five minutes; temperature, 70° F.; result, brown-black.

###### No. 3.

Exposure, three inches magnesium; distance, three feet.

##### Developer.

Pyro (to ounce) .....	2 grains.
KBr (to ounce) .....	8 "
Sulphite of soda (to ounce) ..	22 "
Carbonate of soda (to ounce) ..	22 "

Time, about seven minutes; temperature, 70° F.; result, warm brown (Pages), brown (Ilford). J. TAYLOR.

#### THE STREET CINEMATOGRAPH.

##### PRISONERS COMMITTED.

ALFRED JONES, 23, and Samuel Gold, 18, showmen, of Graham-road, Dalston, were charged on remand at Southwark Police-court, on September 29, before Mr. Taylor, with being concerned together in causing a crowd to assemble in Southwark Park-road on the 22nd ult., and with using indecent and obscene language to the annoyance of inhabitants and passengers.

Evidence was given at the previous hearing by Detective-officers Lee and Brown, that the prisoner Jones was exhibiting a cinematograph on a barrow in the roadway, surrounded by a crowd of lads, and that Gold was describing in vile language the scenes exhibited, and which could be viewed at a charge of a penny. One of the films was produced in court, together with some pictures of nude figures, which were openly displayed. The magistrate ruled that these were classical subjects, but expressed an opinion that the exhibition of the film, in conjunction with the language quoted, was grossly and abominably indecent. He therefore decided that the prosecution ought not to be restricted to the language used, but should be extended to the exhibition itself. Mr. Sims now appeared to prosecute on behalf of the Treasury; Mr. T. W. Moore defended the prisoner Jones; and Mr. Mathews (for Mr. Sydney) watched the case on behalf of Haydon & Urry, Limited, of Islington. The police authorities were represented by Detective-inspector Freeman, M. Division.

Mr. Sims stated that the Director of Public Prosecutions had carefully considered the facts of the case, and had instructed him to ask for the committal of the prisoners on a common-law misdemeanour for exhibiting an indecent exhibition. He thought there could be no doubt that such an exhibition in a public place was a common-law offence.

The Magistrate: It seemed to me to be perfectly clear.

Mr. Sims said he had had to see the film, and he thought there could be no question of the real nature of the exhibition, especially when coupled with the language used by the prisoners. He suggested that, before proceeding with the evidence, women should be ordered out of court. There was only one woman present in court—a tall, elderly female, fashionably dressed in grey, and she reluctantly left the court.

Evidence similar to that given previously having been called, Mr. Moore, on behalf of his client, submitted that the film was not indecent, and stated that the photographer was awarded a medal for it at the Reading Exhibition.

The Magistrate expressed his surprise, and asked who were the Judges.

Mr. Moore did not know, but proposed to put Mr. Haydon in the box.

Mr. Sims: Before you do that, I think Mr. Haydon should be cautioned as to his own position.

Mr. Mathews: As representing Mr. Haydon, I should advise him not to go into the box.

The Magistrate: I think you are exercising a very wise discretion.

The prisoners were then committed for trial, and an application to reduce the amount of bail from 100*l.* each was refused, and the prisoners removed.

#### USING THE EYES AS A STEREOSCOPE.

MR. L. PAXTON, in the *English Mechanic*, gives the following method of obviating the use of a stereoscope in the examination of binocular photographs:—

Supposing *n* and *l* to be the position of the eyes, *r*, *d*, *l*, two pins stuck upright and a third pin stuck in at *p*, it is evident that, looking with the right eye, the pin, *r*, will appear to cover the pin, *p*, and, looking with the left eye, the pin, *l*, will do the same.

On looking with both eyes, slightly squinting, the heads of the pins will appear to unite at that point, and, if small stereoscopic pictures, the centres of which are  $1\frac{1}{2}$  inches apart, be substituted for the pins, they, in like manner, appear to unite at 10 inches behind the stereos. As the size of the stereo prints increases, the distance at which they unite also increases, and the necessary amount of squint becomes less, till with the full-sized pictures  $2\frac{1}{2}$  inches between the centres, a very slight inclination of the eyes is required, the natural accommodating power of the eyes

being sufficient to cause them to unite. They seem, in fact, to coalesce without effort.

Pictures taken with the lenses of the camera the same distance apart as the eyes give the least trouble to unite, as one sees the pictures under the same aspect as the objects they depict.

I have shown at *q* in the diagram the effect of uniting the pictures in the way mentioned by "R. S. D." It will be seen that the amount of squint requisite is greatly in excess of the way I described, and more trying to the eyes.

I know that some people find a difficulty in uniting the pictures; but, on the other hand, many do so quite easily. I have photographed and mounted a very great number of stereos during the last forty years by the method described, and have never found any trouble in doing so. I recently looked at the stereoscopic pictures in the *Royal Magazine* without a stereoscope, and, with one exception, had no difficulty. Some of them were excellent—much better than I should have thought possible from mechanical printing.

#### ACETYLENE GAS-GENERATORS.

At the Congress in connexion with the Acetylene Exhibition held at Budapest last May, Dr. Ludwig read a paper on gas-generators, which is thus reported in the *Engineer*: He gave an account of the progress that had been made in the construction of gas generators during the past year. After a brief but courteous acknowledgment of the huge debt which generator-manufacturers, in Germany, as in this country, owe to Professor Lewis, for his careful experiments on the theory and practice of acetylene production, he began by dealing with carbide-to-water apparatus. Ludwig remarked that the mechanism employed to feed the carbide as required into the water had been greatly simplified, and in most recent forms was fairly trustworthy; but, as it was usually driven by the rise and fall of the holder-bell, this method of procedure had the defect of throwing considerable and undesirable work on the gas-holder, which work, moreover, was apt to vary as the general store of carbide decreased in weight. Carbide-to-water generators were therefore more suited for hand charging, and as such were indicated primarily for installations where a man would be in constant attendance. It will be within the recollection of most readers that Professor Lewes has stated that the output of gas per unit weight of carbide in apparatus of this type rarely exceeds eighty-four per

cent. of the proper amount—a loss which he ascribed partly to imperfect decomposition of the carbide and partly to dissolution of the acetylene in the large excess of water. Unfortunately he has not given any estimate of the relative magnitude of these defects; but, it seems clear that, by proper construction of the generator, imperfect decomposition should be capable of almost complete elimination, for the usual source of this trouble depends on the fact that some of the smaller fragments of carbide fall through the false bottom—when one is fitted—and become coated with a resistant layer of lime sludge. Ludwig did not mention this latter objection, possibly because he considered it had already been overcome in the goods of the best makers; but, referring to the loss of acetylene due to dissolution, he stated that a carbide-to-water generator would work with one gallon of water per 2 lbs. of carbide—a volume which could only absorb two per cent. of the acetylene, assuming the theoretical yield to be 5 ft. per pound. On the large scale the lime sludge might be drawn off, the solid matter allowed to settle, and the liquid returned to the generator, thus decreasing the waste of gas; in smaller apparatus it would be more convenient and cheaper to bear with the loss. Another trouble met with in these generators was the foaming that occurred with certain brands of carbide; and he suggests that this was caused by the use of a material containing aluminium. Aluminium carbide evolves methane on treatment with water; and methane in lime water, he said, always foamed. Experiments with oils, salts, &c., instituted to discover a means of avoiding the difficulty, gave negative results.

Among water-to-carbide generators improvements had been even more pronounced. When the total charge of carbide contained in the apparatus was distributed among a large number of small compartments, and the water was admitted in such fashion that it could only reach one portion at a time, and when the quantity of water admitted each time, some entering the decomposing chamber, was more than sufficient wholly to decompose each portion of the carbide, then water-to carbide machines worked quite as well as those of the opposite construction. The system of permitting water to fall either in drops or as a stream on a mass of carbide was being abandoned; for apparatus of this design were specially liable to excessive heating, accompanied by the inevitable decomposition of part of the acetylene, while they also had the defect of leaving some of the carbide unattacked. This incomplete reaction was not merely wasteful, but was actually likely to prove dangerous if the residues were dealt with carelessly. However, generators of this type, in which the carbide was subdivided into small portions like those previously described, were still being manufactured, and it remained to be seen how they would compete with their rivals. In short, Ludwig's remarks only bear out those made by other observers, viz., that to obtain satisfactory generation, to avoid excessive heating and consequent polymerisation, water must always be in excess at the time and place of actual chemical reaction between the two substances.

Ludwig considered that portable lamps had been improved, but were still far from perfect; that methods of purification were satisfactory, and that, if they were employed, burner troubles would no longer exist. Purification with liquids ensured greater regularity of action than when the same reagents were used as solids, but the former method involved more loss of pressure. When the gas was to be dried again after purification, lime was better than carbide, but precautions must be taken to prevent dust passing into the pipes. In connexion with this latter opinion, it may be remarked that a highly purified acetylene has practically little odour, whereas an evil-smelling gas is, remarkable though it sounds, advantageous, in view of the fact that leaks are more safely detected by the nose than by a disastrous explosion. If the pure but damp acetylene be dried by carbide, the gas is scented again, and it would seem the proportion of impurities thus introduced might be sufficient to make it smell without causing it to be objectionable in other respects. This is a matter, perhaps, on which further experience is desirable before a final judgment can be delivered.

### IMPROVED MUTOSCOPES, &c.

ANSBORO AND FAIRIE'S.

In this invention, which is due to Messrs. Ansboro and Fairie, the series of pictures, *a*, to be presented to the eye are arranged in the form of an endless band, *a'*, each picture being jointed to its neighbour in the band by means of a flexible joint, *b*. The flexible joints are coated alternately, on opposite sides, that is to say, the one joint is coated on the one side of the band, and the next joint on the other side, with an elastic substance, such as indiarubber, so as to give the band a tendency to fold automatically in a V fashion, as shown at fig. 3. By means of a revolving plate, *c*, which receives intermittent motion from an eccentrically arranged wheel, *d*, provided with means, such as a pin, *e*, for actuating the plate, each picture is presented before an eyehole, *w*, in the case, *g*, of the instrument for a brief interval of time, and is then suddenly turned over, and its place taken by the next succeeding picture in the band. As the pictures in the band fall down from the plate, *c*, aforesaid, they fold up automatically (see dotted lines, *i*, fig. 3) within a guide casing or chamber, *h*, which is preferably of a U shape, with a central division or partition, *h'*.

The revolving plate, *c*, has its axle, *c'*, to which it is rigidly secured,

carried by the brackets, *m*, and, as will be clearly seen from fig. 1, the said axle, *c'*, is out of the centre of the wheel, *d*; the result of this is that, as the wheel revolves, its projecting pin, *e*, alternately engages itself with, and releases itself from, the projections, *j*, *j'*, provided for the purpose, on the plate, and which are equidistant from the centre of its axle so as to impart to the plate the intermittent motion. The wheel, *d*, can be kept continuously in motion by means of suitable mechanism such as the gear wheel, *k*, operated by the turning of a handle, *l*, or by clockwork.

The pictures can be viewed through a single opening, *n*, provided with a magnifying lens, *o*, or, when the series of pictures in the band are in

duplicate, they can be viewed stereoscopically through two openings, one for each eye.

*p* is a strengthening cross board, to which the casing, *h*, can be secured at its upper end. *p'* is a cover with an opening, *p''*, at the centre, through which the pictures can be seen as they are presented by the plate, *c*. *q* is an opening at the upper end of the instrument, and which is provided with a hinged lid, *q'*, capable of being raised to the proper angle (see dotted lines, fig. 3) in order to serve as a reflector for throwing light upon the pictures.

For the purpose of keeping the pictures in place as they are revolved, the plate is provided at each end with metallic discs, *c''*.

In the arrangement figs. 4 and 5, the plate, *c*, mounted rigidly on its axle, *c'*, has its projections, *j*, *j'*, provided with escapement pieces, *r*, *r'*, each of which is slotted and is capable of being adjusted in position upon the projections by means of the screws. The mechanism for revolving the plate consists of a driving pulley, *s*, on the axle, *c'*, and from which passes a cord, *s'*, to the small pulley, *s''*, on the spindle, *s'''*. Made in one with the pulley, *s''*, is a toothed wheel, *s'''*, which gears with a toothed wheel, *s''''*, on spindle, *s'''''*, made one with an elliptical wheel, *s''''''*, which

latter gears with the elliptical wheel,  $s^8$ , turning upon the spindle,  $s^9$ . The pin,  $e$ , inserted in the elliptical wheel,  $s^8$ , is capable of engaging once in each revolution with one of the escapement pieces,  $r, r^1$ . As will be seen, the axle,  $c^1$ , of the plate,  $c$ , is journaled at the one side in the head,  $s^{11}$ , of the fixed spindle,  $s^8$ , and eccentrically of the wheel,  $s^8$ . As is clearly shown at figs. 6 and 7, owing to this eccentric arrangement, the pin,  $e$ , will be caused, once in each revolution of the wheel,  $s^8$ , to engage one of the escapements (see fig. 7), with the result that the plate will be turned over, that is, moved through half a revolution, and then release itself from the escapement and pass round free of the other escapement (see figs. 4 and 6).

As the movement of the pin,  $e$ , in its path, is faster or slower, according as the longer or shorter radius of the wheel,  $s^8$ , is in line (through the gearing of the wheels) with the shorter or longer radius of the wheel,  $s^7$ , the pin and these variable movements are so arranged that the former will be engaged with the plate,  $c$ , during its maximum movement, and released therefrom when its movement is at a minimum, thereby ensuring that each picture, as it is moved forward in succession by the

Fig 5

plate, shall remain at rest for a much longer time than is taken to effect the change from one picture to another.

In order that the friction on the flexible joints, due to the movement of the band, may be reduced to a minimum, the band, in its path of movement, rubs merely against two wire rails,  $t, t$ , arranged around the interior of the chamber,  $h$  (as shown at fig. 3), at a distance apart corresponding to that between the two deep indents,  $u, u^1$  (fig. 4), on each edge of the picture plate,  $c$ . The middle partition,  $h^1$ , of the chamber,  $h$ , is similarly furnished, and both its wires,  $t^1, t^1$ , are prolonged at the top into the indents on the edge of the plate, so that the plate, in revolving, passes by them like a comb, without actually touching, and so prevents any possibility of the band being caught during its movement between the upper part of the partition and the edge of the plate.

To facilitate the movement of the band from front to rear, at the bottom of the chamber, the latter is there formed with a curve that may be either circular or cycloidal.

$w, w$ , are bent springs attached to the disc,  $c^2$ , of the picture plate, and which bear against the fixed disc,  $v$ , so as to act as brakes.

CHARLES RALEIGH'S.

The inventor, Mr. Charles Raleigh, points out that, in mutoscopes as hitherto constructed, it has been usual to arrange the pictures on flexible arms, which project radially from a common centre. In the circular path traversed by the pictures, or by the arms carrying the latter, a stop is presented which has the effect of temporarily arresting the movement of each successive picture whilst in the line of vision.

The continuation of the rotative movement has the effect of liberating each picture and allowing it to resume its normal and radial position. According to this method of working, the bending of the pictures, or of the arms on which they are carried, provides but an extremely limited surface for the arresting stop to engage with, the consequence being that, unless the pictures are mounted with great accuracy, there is a liability for more than one picture to disengage itself at a time, the regularity in the apparent movement of the object being thereby marred.

According to his improved method of construction, instead of arranging the pictures radially or upon arms, so that, on arriving in position for observation, they travel in a direction at right angles to their surfaces, he mounts them in such a manner that, in travelling towards or away from that position, they move edgewise, or substantially in the plane of their surfaces. On reaching a certain point in their journey, they arrive

against a curved guide, so arranged as to gradually deflect them laterally to an angle of from sixty to seventy degrees or thereabouts. On passing beyond the curved guide, they are successively released, and, straightening out, resume their normal attitude.

In mounting the pictures, they are arranged each with its edge slightly

in advance of that of the following picture, the extent to which each picture is in advance being permissible considerably more than is practicable with mutoscopes as ordinarily constructed and worked.

In the accompanying drawings, fig. 1 is a view of a mutoscope having the pictures arranged according to my improved method. Fig. 2 is a face view, the front portion of the casing, which is furnished with the lens for viewing the pictures, being removed. Fig. 3 is a diagrammatic view of a number of picture cards mounted in the manner illustrated in figs. 1 and 2, but arranged spirally upon the spindle. Fig. 4 shows in side elevation and perspective another method of mounting the pictures, whereby they are arranged parallel with, and so as to overlap, each other. Fig. 5 illustrates a method of working where the cards are

mounted as in fig. 4, and arranged in sections upon an endless carrier. Fig. 6 is a perspective view, showing a number of pictures mounted parallel with and so as to overlap each other and arranged upon a circular foundation.

$A, A$  are the overlapping picture cards or arms, which are mounted upon the spindle,  $B$ , the latter being carried in the bearing,  $C$ . Motion may be imparted to the spindle,  $B$ , by means of the handle,  $b$ , through the medium of the worm,  $b^1$ , and worm wheel,  $b^2$ .  $D$  is the curved guide by which the

picture cards are deflected laterally, and allowed to descend upon a stop,  $x$ , in position for being viewed through the lens,  $r$ . The picture cards or arms may be rectangular or wedge shaped in plan.

According to an alternative mode of mounting, shown in the diagram (fig. 3), the picture cards,  $A$ , are arranged in the same manner as in figs. 1 and 2, that is to say, each with its edge slightly in advance of that of

the following picture, but the series of pictures are placed on the spindle, *n*, in the form of a spire. When mounted in the machine, each picture is deflected by the curved guide, *v*, and received on the stop, *x*, as explained with reference to figs. 1 and 2.

The series of picture cards may be arranged to work rectilinearly, as shown in figs. 4 and 5. In fig. 4 is illustrated a series of picture cards, *a*, mounted on an endless band or carrier, *n*<sup>0</sup>, each card being arranged with its edge slightly in advance of the one immediately following. In fig. 5 the same method of mounting and working pertains, but the picture cards, *a*, are arranged in sections, the section with their carriers, *n*<sup>0</sup>, being mounted upon an endless chain, *c*, which may be operated by the chain wheels, *c*<sup>1</sup> *c*<sup>2</sup>. The picture cards may be mounted on an endless band, arranged to pass round one or more guide rollers.

Or the series of picture cards, arranged as above described, may be mounted so as to follow a circular path, as shown in fig. 6, in which the series of overlapping picture cards, *a*, are mounted upon a circular plate or boss, *n*<sup>1</sup>, the latter being keyed on a spindle, *n*<sup>2</sup>, carried on suitable bearings, *c*<sup>1</sup>, operated by means of a crank handle and worm gearing as described with reference to figs. 1 and 2. A guide or projection, *n*<sup>3</sup>, is mounted in the casing of the machine for deflecting each picture card in succession, so as to bring the same to the position for observation.

### THE "LABORATORY" LATHE-BED LANTERN.

This new lantern has been designed by Messrs. Newton, 3, Fleet-street, specially for scientific work in laboratories and lecture theatres. It consists of a ribbed aluminium body carrying a 4½ inch condenser, mounted on a solid, accurately planed lathe-bed, base 3 feet long, on levelling screws.

The focussing lens and slide-carrier are carried on separate standards, and both they and the lantern will slide and clamp in any position on the "V and flat" iron bed. There is a clear space of about 14 inches between the optical centre and the table on which the lathe-bed stands, thus allowing ample room for physiological recording apparatus, &c., for which this form of base gives ample facilities. The whole instrument, being constructed of metal, is very rigid and free from vibration, and is not affected by the heat of the arc light. It is, of course, not very portable, though it can easily be carried from one room to another. As the fittings are all readily removable, the base can also be used as an optical bench for laboratory work, where accurate centering and motions and easy interchange of apparatus are requisite.

### SPEARLING'S CHILDREN'S OPAQUE LANTERN.

This lantern has been designed by Mr. Spearling solely with the object of showing opaque objects and pictures on the screen.

The whole of a drawing or painting, five inches square, can be shown five feet in diameter on the screen with sufficient illumination for a small audience.

Flowers, shells, the face and works of a watch, coins and curios of various sorts, can also be well exhibited.

It is fitted with two incandescent gas burners, which only require ordinary house gas brought to them, by an indiarubber pipe from the nearest gas bracket. It is therefore absolutely safe, and requires nothing but turning on the tap and lighting, and is at once ready for use. At the back of the lantern can be attached a double roller, carrying a roll of paper on which children can make drawings and paintings, which can then be projected as a moving panorama on the screen. Christmas cards, butterflies, and similar objects show excellently. The instrument has been put on the market by Messrs. Newton & Co., 3, Fleet-street, London.

### THE "GASLYT" LANTERN PLATES.

J. J. Griffin & Sons, 20-26, Sardinia-street, Lincoln's Inn-fields, W.C.

Messrs. GRIFFIN are introducing the Gaslyt lantern plates, the name of which indicates the fact that, like Velox, all manipulations, from the removal of the plate to the final development and fixing, may be conducted in gas or lamp light, no dark room being required. Messrs. Griffin say: "Amateur photographers of the old school seem to view with some misgiving this growing independence of such an ancient institution as the dark room, but we venture to believe that the majority will gladly sacrifice the darkness, the discomfort and unhealthiness of the ruby lamp or the comfort resulting from the new methods. The property of being able to develop Gaslyt lantern plates in a brighter light is of particular advantage to the tyro, as he can judge the density with every certainty, a difficulty which all experienced lantern-workers will affirm."

The following are the instructions for working the Gaslyt lantern plates:—

**Exposure.**—With a negative of average density, employing an ordinary gas flame as the source of light, from one and a half to two minutes, at a distance of four inches, will be found to be sufficient. If warm tones are preferred, the exposure must be more prolonged. To

secure the best results the use of magnesium ribbon as an illuminant is recommended. By burning one inch of ribbon at a distance of eighteen inches from the negative splendid black tones may be obtained. When using a thin negative, the distance should be increased. For sepia tones, use three inches of magnesium ribbon, and, for warm brown tones, four inches at the same distances from the negative.

**Development.**—After exposure, develop with the following. For this purpose, you need not have a dark room, but can conduct your operations at a distance of six feet from an ordinary gas flame or lamp light.

#### FOR BLACK TONES.

Water .....	8 ounces.
Metol .....	4 grains.
Sodium sulphite crystal .....	75 "
Hydroquinone .....	16 "
Sodium carbonate crystal .....	280 "
Potassium bromide .....	16 "

#### FOR WARM OR SEPIA TONES.

Solution (as for black tones) .....	1 ounce.
Water .....	2 ounces.
Potassium bromide solution (ten per cent.), 10 drops, or 1 grain of the solid substance.	

With the above developer, assuming exposure to have been correct, development should be complete in about two minutes for black tones; development for warm tones is complete in about four minutes.

**Fixing.**—On completion of development, the plate should be immersed, without previous washing, in an acid fixing bath, where it should remain for about four minutes. Griffin's Rapid Fixer, or the acid hypo fixer in cartridges, form, when dissolved in water, according to instructions, are excellent baths for the Gaslyt plates. The following formula may also be used:—

#### STOCK SOLUTION.

Sulphite of soda .....	4 ounces.
Citric acid .....	½ ounce.
Water to make .....	20 ounces.

To prepare the fixing bath dissolve—

Stock solution (as above) .....	6 drachms.
Soda hyposulphite ... ..	4 ounces.
Water .....	20 "

**Washing.**—Half an hour's washing in running water is sufficient.

#### CAUSES OF FAILURE AND THEIR REMEDY.

**White Deposit** all over the film is due to milky hypo bath or imperfectly filtered tap water. Use a small piece of wet cotton-wool, with which wipe the film.

**Black Specks** on surface of film may be also removed by the above method. It is, in fact, a good plan to make a practice of wiping each plate during the final washing, thus avoiding the risk of permanently disfiguring the slide.

**White Spots** on finished work may be caused by dust specks on negative during exposure. Wipe carefully both lantern plate and negative before printing. Pour developer evenly over the film.

**Greenish or Brownish Blacks.**—Too much bromide in developer; weak or spoiled developer; over-exposure.

**Fogged or Veiled Results.**—Exposure to too strong a light previous to development. Avoid direct gaslight.

**Lack of Contrast.**—Over-exposure or too thin a negative. Cover negative with a sheet of tissue paper, and give short exposure, nearer to source of light.

## Correspondence.

### HOW A LENS IS MADE.

To the Editors.

GENTLEMEN,—I shall esteem it a favour if you will kindly announce to your readers that I have an interesting set of forty slides, entitled "How a lens is made," which I shall be happy to place at the disposal of secretaries of photographic societies.

The slides illustrate the various processes of manufacture as carried out in the optical factory of Mr. C. P. Goerz at Berlin-Friedenau. A complete description, for the use of the lecturer, accompanies the slides, and I think the subject would form an interesting item upon the syllabus during the winter season.—I am, yours, &c.,

4 and 5, Holborn-circus, London, E.C.  
September 29, 1899.

PAUL PONGE.  
(Pro C. P. GOERZ.)

FROM Messrs. Morley & Cooper, of 70, Upper-street, Islington, we have received their list of high-class English-made hand cameras, also their lantern catalogue, with list of accessories, sets for hire, &c.

### LANTERN MEMS.

At the Camera Club recently, some beautiful examples of three-colour printing in transparencies were projected on the screen as illustrations of a most interesting lecture and demonstration by Mr. Sanger Shepherd. For brilliancy of colour, accurate register of films and fidelity to nature it can fairly be said they were *par excellence*, and, if as stated, no great skill is required to produce them or an expenditure of unreasonable time, there should be a great future before this process. The lecturer stated he was indebted to Mr. Saville Kent for the negatives from which he obtained some of his most brilliant results, notably the butterflies, Australian flowers and foliage, but the reproduction of a picture with a bay-coloured horse pleased the audience immensely.

Those who had seen demonstrations by the Ives process, examples of the Joly method, and the specimens shown at the Society of Arts and Crystal Palace of Bennetto's work, could not but admit that these slides, which Mr. Sanger Shepherd said he produced himself on the day of the lecture, were the closest approximation to the colours of nature of any of them, and as lantern slides the most practical, for only an ordinary lantern is required, and there are no lines, overlapping of colour, or anything that, as far as could be then seen, could be taken exception to, notwithstanding they were critically viewed through an opera glass.

The new American film was credited with giving assistance to this end, and the aniline dyes used to colour the three transparent films were produced after considerable trouble, for ordinarily the scum or impurities contained in commercial dyes prevented satisfactory results. The inevitable syndicate is formed to exploit the method for which the two gentlemen named are responsible, and, if an average worker can produce results at all approximating to those shown, there should be money in the scheme.

I NOTE that the biograph has gone to the war, and, if anything in the way of a battle piece is possible, Mr. Dickson, the gentleman in charge, is just the man to secure it. As money is no object with a Company such as this, and the technician mentioned is a man full of resources, the British public will, no doubt, through the medium of

the instrument at the Palace Theatre, be treated to some most interesting episodes. I can understand a satisfactory portrayal of a battery getting into action, galloping to a position, unlimbering, taking the range, firing, and perhaps limbering up and retiring, also the preliminaries of a gallop and charge by cavalry; but, when it comes to the actual fight, then the distance dictated by prudence, if not insisted on by the general in command, will preclude anything like a near enough approach to the scene to get a presentable picture except by long-focus lenses, say, twenty to thirty inches. Equivalent foci are used, for with ordinary lenses the photograph will only be a microscopical reproduction of the scene. I have often witnessed military manoeuvres and sham fights, and should have liked to portray what the eye sees, but the camera of ordinary make, with lenses of moderate length of focus, is quite unequal to the task. Mr. Dickson may be equipped differently to what I suppose for his biograph camera and so upset my conclusions. Any way, I know he has with him cameras other than the biograph, so perhaps he may obtain some set scenes as well as animated.

I MUST congratulate Messrs. Wilson & Son on the very comprehensive way they have gone to work over a subject that is always of interest to lovers of art, and have prepared for portrayal in the optical lantern a set of no less than one thousand slides of Italy, embracing the chief cities and places of historical or artistic interest, paintings by the old masters, statuary and sculpture, &c. Art and science teachers have here at their command a splendid choice of illustrations for their lectures, while travellers and tourists can supplement their own photographs with pictures and examples of art that they themselves would not be able to obtain during a holiday limited for time. Their idea of an album of miniature photographic prints of these subjects is a very good one, and enables intending customers to see, and therefore understand what the subject is like, which, of course, cannot be done from a title only. The principal opticians, lantern-makers, and slide dealers keep this album for their customers' inspection, or to send them on application for a limited period, so that the customer may choose for himself, and, unless he is very exacting in his requirements, he will be able to make a selection that should add materially to the value of his collection of slides, besides giving him the power to illustrate the particular points in his lecture he wishes to emphasise. Mr. Wilson's short *resumé* of English history hardly justified the adjective, for already it is so long and means so large a collection of slides that it is only the very large dealers that would stock them all. This does not, however, detract from their merit or neutralise their usefulness for educational work.

THE martial spirit of the nation just now is exemplified at every public meeting and place of entertainment, and those who have negatives of the "Soldiers of the Queen" are reaping a rich harvest both for lantern slides and illustrations for journalism.

G. R. BAKER.

## MY EXPERIENCES OF "SPIRIT PHOTOGRAPHY."

The experiences of Mr. Mark Blow, of Sydney, N.S.W., given in a recent issue of this JOURNAL, recall very vividly to my memory the many hours, cash, and material I have wasted in my fruitless endeavours to get even the ghost of an image of a "ghost" on a sensitive plate. For many years I have been deeply interested in so-called spirit photography, and my first experiments in that particular direction were made a few months before the late Mr. J. Traill Taylor gave to the world his famous paper on the subject, in the month of March, 1893 (see THE BRITISH JOURNAL OF PHOTOGRAPHY, March 17, 1893). At the time when the *Fortnightly* (January, 1893) was published containing an article on "Ghosts and their Photographs," by the Rev. H. R. Haweis, M.A., I was living within a stone's throw of a then, and perhaps now, well-known "circle," in the Camberwell New-road, S.E. The man with whom I lodged, though not a professional medium, was a member of the circle, and one of those individuals whose good (or bad?) luck it was to see spirits at all times (he, by the way, was a builder by trade, and not a publican). Here, then, was my opportunity for experiment. Somehow or other I had not the nerve in those days to attend dark sciences and spiritualistic manifestations, such things were all new to me, for I was one "from the country," and scarcely of age. By degrees, however, I mustered up courage, and as a beginning we had little sittings in the parlour.

The name of my friend was Harris, and he was quite as anxious as myself to obtain pictures of what he, and he alone, saw. Moreover, he shut himself up in the darkened parlour one evening with my camera focussed ready, six double backs, and a plentiful supply of magnesium ribbon and a flash lamp. For three hours he sat there and did not speak, but exposed my twelve plates by aid of magnesium whenever he saw a psychic form in the room. I developed most carefully six of those plates in six different ways, and sent the remaining six to as many professionals. All produced the same result—nothing, except, of course, the wall paper, curtains, &c., that were in the room. Not a trace of a spirit form could we find. My friend was disappointed, so was I, for he assured me most emphatically that figures were seen, and, what is more, they stood still while the ribbon burned or the powder flashed.

After hearing Mr. Taylor's lecture, we decided to try again with faster and isochromatic plates. We did so, and on this occasion I remained in the room the whole of the time and manipulated the camera and lights whenever my friend said that spirit forms were about. Needless to say, I saw them not, but relied on the truthfulness of my friend. Again, and on two subsequent occasions, the same result—nothing.

I then made arrangements for the attendance of a professional medium; but, before I could proceed with further experiments, I was called away on business to Bradford, where I remained for some years, and never returned again to London to live. It was a fortunate matter that I went to Yorkshire, for, as almost every one knows, this shire and its neighbour, Lancashire, are the very hotbeds of spiritualism. I had not been in that district long before the thought of photographing "table-turning" parties occurred to me, and, under a *nom-de-plume* (K. N. Pepper), I wrote an article on the subject to *Photography* (November 8, 1894). In reply thereto three or four letters, wise and otherwise, appeared, but whether any one else took up this seemingly idiotic branch of photography I know not. I did, with a determination to get something. I attended many table-turnings, both by day and by artificial light, made some scores of exposures upon the unseen influences that were apparently at work, but my results were always the same—nil.

About this time the Bradford Photographic Society was formed, and it was at one of the meetings that I met a gentleman, well known in the photographic world, who I will now call Mr. Smith. I soon found out that what interested me also fascinated Smith, and we read and discussed together *The Veil Lifted*, *Twenty Photographs of the Risen Dead*, and a few other books. Finally we resolved to go into partnership in the matter and engage the best medium it was possible to get. From the preface of *The Veil Lifted* we got the following information: "The term 'spirit photographs' is generally used to describe photographs of psychic entities which cannot be seen by ordinary persons, but can be photographed by a medium, or with the help of a medium, and with the co-operation of these unseen entities. Such portraits are obtained both indoors and in the open air, with and without a background, by natural light and by artificial light, and in the case of 'materialised' forms at sittings, which are visible to every person present, the portraits have sometimes been taken by light produced by spirits, the exact nature of which is unknown."

Anent the latter statement, it is interesting to note that there appeared in these pages, and in the *Daily Telegraph*, a few months ago, an account of how a materialised form nearly lost his life by suffocation, and how the audience went to his help. They found the materialised form to be a living human being, who had accidentally swallowed the small electric lamp that had been placed in his mouth for the purpose of illuminating his face when he, the materialised form (*sic*), appeared before the audience. But let us for the nonce let such things slip.

I will name the medium that we obtained—Jones—Mr. Jones, of Leeds-road, Bradford. He was considered by all who knew him to be an excellent medium. I say excellent, because he told me that for twenty years he had never been "clear" of a spirit form; he met them in the street,

they were beside him while at meals, they walked round his bed, took tram rides with him, and did many other wonderful things. Such a man we prized, for he was indeed a treasure, and one we intended making the most of.

"Aren't you nervous and afraid to have these ghostly forms always pottering about round you?" I asked.

"Not at all," he replied, "I should be miserable if they were to leave me."

During our conversation I gathered that he knew absolutely nothing of photography, and that he was extremely anxious to sit for us as he felt certain, nay, was quite sure, that the astral bodies could not help being taken. Needless to say, neither I nor my friend Smith could see our uninvited guests, so we were content for the nonce to believe Jones, as they were visible—very plainly, too, he said—to him alone.

"As I cannot see the forms," I asked, "perhaps you will tell me their colour?"

"Certainly," he replied; "they are a misty light blue, a kind of a hazy, airy form."

"That being the case," I said, "they are certain to be photographed," because light blue, as every one knows, photographs white.

We adjourned on that particular bright Sunday afternoon to Smith's quiet parlour, situated in the Lister Hills district of Bradford. We draped the room with deep red and black curtains, for reasons that are obvious to all who know anything of photography.

We fixed up our cameras, focussed the curtains, and made a few exposures on the empty room. Our plates came out of the developing operations like clear glass; not a ghostly form was to be seen on them, even though our spiritualistic friend declared there were some misty forms promenading on the carpet. Any way, we missed them.

Taking the medium by my side, I explained to him the angle of view my lens embraced, and begged that he would tell me when a spirit form was in the centre of the picture, at which moment I would expose. I said I preferred a female figure, if one should come, as I had been told that a spirit face is a realisation of a high ideal of beauty, the beauty of which we poor mortals cannot comprehend. The medium gazed for a few moments into the empty room.

"There, there!" he exclaimed; "there is one, a perfect angel!"

I made an exposure, and developed at once; but, alas! she left no trace even of a shadow behind.

As the next experiment, we sat the medium in the centre of the room and focussed him, "because," he suggested, "they may gather round me and stay long enough for you to make a much longer exposure."

After sitting a few minutes he said, very calmly, "There is a good-looking young female against my knee."

"Then take her on it, and hold her tight for a few seconds," I said.

But my suggestion seemed to annoy him, and I found I must work more seriously.

"There is yet another," he said, "behind my chair."

Both these visions stayed, so Jones said, long enough for me to give a longer exposure; but again the same result—nothing, except, of course, the medium, who sat there right enough, but he was alone, his female friends did not show themselves. We then had tea, and waited until the sun had set. Proceeded we then again to the parlour with a flashlight outfit. For upwards of an hour we sat in that darkened room, flashing magnesium and exposing plates whenever our friend, the medium, said we had misty visitors, but with no success whatever. We tried every possible means on that and other days and with other mediums for getting even a shadow of some ghostly visitors, but were doomed to disappointment.

I do not doubt for one single moment that mediums, indeed, spiritualists generally, do see psychic forms; anybody can see them if their minds are weak enough to be worked up to such a high pitch of imagination. Ghosts, as spirits are vulgarly termed, do not, I believe, exist in reality; they are simply brain pictures or day dreams of a pronounced type, and nothing more. If they really did exist, their misty forms could not escape the camera, for has it not been proved times out of number that things invisible to the naked eye can be successfully photographed?

RICHARD PENLAKE.

## LANTERN LECTURES.

WITH so many of our amateur associations organizing lecturette competitions for their members, and, judging from the keen competition that invariably follows, it looks as if a fresh impetus is likely to be given, not only to amateur photography, but likewise to single lantern work as well. That these competitions do much to assist secretaries and others in providing interesting matter for the winter season, as well as tending to improve the quality of amateur work, is at once recognised, but there is a further advantage accruing from such competitions, they are instrumental in bringing forward numerous individuals who possess undoubted literary ability, who otherwise would never dream of standing before an audience and delivering even a short address.

No doubt there are many persons who, from a feeling of nervousness, shrink from appearing on any public platform who find such lecturettes good training for more important functions, for their delivery.

before the members of a photographic society practically means addressing one's friends and acquaintances only, and is a very different ordeal to face as against appearing in the rôle of a professional lecturer in some large theatre or town hall before a sea of faces which sometimes number three or four thousand.

With beginners in public lecturing, no matter how they may buoy themselves up with the hope that their nerves will carry them through, there is always what may be termed a "baptism of fire," and he who can for the first time ascend the steps of a platform and suddenly face a sea of three thousand faces, will certainly find it takes a lot of nerve, probably far more than he has any idea of, to run the gauntlet without showing signs of the nervousness that is sure to seize him. This nervousness may make its presence felt in more ways than one, and affects different individuals in various ways. The writer can well remember what took place at his first "baptism," when appearing before an audience of probably three thousand souls. As to nervousness prior to going on the platform, it practically did not exist, but no sooner was he called upon to step forward and begin speaking than a dreadful sense of weakness at the knees began to manifest itself, but, "setting a strong heart to a styè brea," as we say in Scotland, in a few minutes this trembling passed off, and he was enabled to run right through without the slightest hitch. There is no doubt, however, that, if any nervousness be experienced, it will make its presence felt in the vicinity of the knees, and for a moment or two the feeling of weakness is dreadful to contemplate. The writer has known others whose experience was of a somewhat different character. In their case the nervousness took the form of actually making them become tongue-tied. They suddenly experienced a swimming sensation in the head, and for the life of them were powerless to articulate a single sound. Luckily, these awkward attacks do not last long, and any one determined to face the ordeal should set himself determinedly to face it out.

I have often been asked by beginners in lecturing if there is any means of warding off such feelings of nervousness, and if I approved of a good stiff B. and S. or other stimulant, which strange to say, almost every one imagines to be the best preventive. In this there lies a big mistake; all stimulants I firmly believe to be worse than useless in such circumstances. At a juncture of this kind one wants a clear and cool head; a good dinner or other repast partaken of about half an hour previously is the best stimulant I know of, and, if there be any means of assisting a beginner to get over his baptism of this sort, I believe it lies in a direction in which very few ever think of looking. After now nearly twenty years of public lecturing I don't know what nervousness on a platform means, and I invariably walk on and commence lecturing with the lights full on, and get these by prearrangements turned down at the exact moment; but, were I to have to face my first baptism again under similar circumstances to those I experienced the first time I stepped upon a platform, I should certainly arrange matters differently, and only walk on the platform after the lights were lowered and the introductory slide projected on the screen. This may not entirely get rid of nervousness, but I can truthfully state that those to whom I have recommended it when first they appear in public have thanked me for the hint, and stated they did not know what they would have done had they faced the audience in full gas or other light.

Some individuals who aspire to public lecturing never succeed in it, simply by reason of not possessing a sufficiently powerful voice or the natural ability to frame a really interesting lecture.

The first of these deficiencies is fatal, and, strange to say, there are numbers who imagine they possess plenty of power of voice who utterly fail to make themselves heard beyond a few feet from the platform.

Of course, there is a great difference in the acoustic properties of theatres and halls. Some prove delightful places to speak in, others try one's powers of voice very severely, but a practised speaker in a few seconds will gauge the right amount of power to use, and which will reach the farthest corner of the theatre and come back to himself.

This should never reach what may be termed the bawling stage. If a speaker cannot do this with his natural voice without strain or effort, he is not possessed of the physical ability for public lecturing, and should refrain from following out such a course. A good well-trained voice is of the first importance, and any one possessed of it should take good care of it. The speaking for a period of an hour and half to two hours straight on end may, at the close, tend to introduce a little hoarseness, but it seldom displays itself during the time of speaking—it generally puts in an appearance afterwards, when the voice resumes its normal condition; this hoarseness will pass off in a few hours' time without any applications to the throat or vocal organs. With those in the habit of speaking much in public it has come to be recognised that the muffling or wrapping up of the neck and throat is about the worst possible precaution to take against cold.

No doubt, after speaking a long time to a large audience in a heated hall, there is a certainty of any one becoming overheated; but this soon passes off when one has finished, and it does not take long in a well-ventilated ante-room for any one to reach his normal temperature. Continuous wrapping and muffling of the throat is apt to engender a delicate condition of the throat and vocal organs, and hence does more harm than good.

Literary skill in framing a lecture is another most important factor,

and the best results are certainly produced when a lecturer is speaking about events or scenes that he is familiar with. In framing a lecture, attention must likewise be given to the duration of time each slide is allowed to remain upon the screen, and this is of far more importance than many imagine. I have known some green hands keep a particular slide on for twenty minutes, and then rush three or four through in a few seconds.

Long introductions prior to showing the first slide should also be avoided. This is apt to weary an audience at the outset, and, if this is allowed, it is very difficult to dispel the impression later on, for "first impressions are always strongest." It is almost imperative that a lecturer gets on good terms with his audience at the very outset. This may be effected in a variety of ways, and perhaps as good a method as any is that advocated by the versatile Andrew Pringle, who always contrived to set off a few fireworks, as he termed it, just at the start. This seldom fails to place an audience in good humour, and then a practised lecturer will know how, by sudden turns from grave to gay, to keep his audience in wrapped attention throughout.

The introduction of songs and other items of music does much to brighten up some forms of lectures, but it is questionable if a lecturer should indulge in such singing himself. In the West of Scotland we have one gentleman who has done perhaps more than any one in the kingdom to popularise limelight lecturing, and he invariably introduces a few songs in his lectures; but, having a long purse, he can afford to pay for the very best talent both in male and female voices, and he is too practised a hand to overdo it in this respect. His lectures have been elevated to a very high standpoint indeed, and, whenever it is known he is to give a lecture, the demand for seats is far in excess of accommodation.

Of course the songs that are introduced are specially selected, and invariably bear some reference to the subject he is treating.

The introduction of much that may be termed "A Variety Entertainment" with a limelight lecture may be popular with some kinds of audiences, but for the better class of lectures is not to be commended.

Such lectures as deal with mere matters of holiday travel seldom give much trouble to frame or deliver, simply by reason of the party *knowing what he is speaking about*; and these are frequently very enjoyable indeed, provided the speaker makes a strong determination to avoid reading his description, in this marking a strong contrast to the man who stands up and reads from a book a description of this or that scene or event which he never saw nor took part in.

It is such amateur lecturers as these who have done much to injure limelight lecturing throughout the length and breadth of the kingdom.

A really good limelight lecture takes far more trouble and thought to place together than many imagine, and when any one is possessed of the capability of not only taking the pictures themselves, but eventually making their own slides from the same, and describing such in person in a free, natural manner, then we generally get something that is worth seeing and listening to. That our various photographic societies are alive to this would appear tolerably certain from the interest that is being taken in the lecturette competitions that now annually find a place in their proceedings.

T. N. ARMSTRONG.

#### FOR THE LANTERNIST.

Those who possess lanterns furnished with spring-fitted holding plates will, doubtless, agree with me when I say that the task of inserting framed

slides into such lanterns is a very difficult, if not quite impossible, one for one person to accomplish satisfactorily.

The difficulty experienced is very annoying to the lanternist, and, moreover, it is presuming on the good nature and patience of the

audience to expect them to wait whilst the operator is "fumbling" with his lantern.

The object of this article is to describe a simple method by which this difficulty may be entirely obviated, and the task of inserting framed slides into the lantern, instead of being, as heretofore, a source of vexation, becomes a pleasure.

A glance at the two diagrams (figs. 1 and 2) will show the principle of the method.

A hinge, *A*, is fitted to the lantern in the position shown. This hinge should extend right across the lantern, so that the stage may be pressed evenly together. The hinge consists of four separate pieces of brass; *A* and *C* are in one piece, the others are separate, and hinged in the manner shown. Now, when the handle of the hinge—if we may so call it—is upright, as in fig. 1, the spring will be expanded, and the plate, *B*, for the insertion of the slides, closed. The operator, when he desires to insert his framed slide, pulls the hinge, *A*, down, as shown in fig. 2. This obviously presses the top spring in and widens the space, *B*. The lanternist now catches hold of *C* and *D* with the fingers of his left hand, and presses *C* close up to *D*. This widens the space, *B*, at the bottom, and with the right hand the slide is placed in the stage. When the slide is correctly placed, *C* and *D* are released, and the hinge, *A*, pulled up again, allowing the spring to expand and pull the plate, *B*, close against the framed slide, thus holding it tightly in position.

When he desires to take the slide out and replace it by another, the operator has simply to reverse the method of procedure described above.

It will be understood that the accompanying diagrams only represent the stage part of the lantern, *r* being, of course, the tube holding the condenser.

No doubt the lanternist who wishes to make every part of his preparations, &c., as easy as possible will obviate the difficulty encountered in inserting framed slides by adopting this simple yet effective method.

THEODORE BROWN.

#### THE NO. 2 FOLDING BULL'S-EYE KODAK.

KODAK, LIMITED, direct our attention to their new No. 2 Folding Bull's-eye Kodak, which, while taking pictures of the large size of  $8\frac{1}{2} \times 3\frac{1}{2}$  inches, closes up to  $1\frac{1}{2}$  inches in thickness.

The No. 2 Folding Bull's-eye Kodak is on the cartridge system, and takes a spool of film for twelve exposures. It is provided with an entirely new arrangement in the form of a removable spool-holder, which renders the operation of recharging the camera exceedingly simple and easy.

Constructed of wood covered with leather, the new Kodak is extremely light, and is conveniently carried by means of the handle attached to the end of the camera, or it may be slipped into an overcoat pocket. Stand as well as hand work may be undertaken, as the baseboard is provided with socket for tripod screw.

The size of the camera closed is  $1\frac{1}{2} \times 4\frac{1}{2} \times 7\frac{1}{2}$  inches, the weight, 15 ounces, and the length of focus of the lens,  $4\frac{1}{2}$  inches.

The levers controlling the stops and time exposures are conveniently situated, and a third lever, actuating the shutter, is simply pushed to right or left alternately for snap-shots.

#### THE VELOCITY OF METEORS FROM PHOTOGRAPHS.

DR. W. L. ELKIN, director of the Observatory at Yale University, writes as follows in the *Astronomical Journal* (No. 469, p. 102):

"We have been experimenting with an apparatus for determining the velocity of meteors photographically, on a principle similar to that devised by Lane as long ago as 1860, and to that used by Zenker in 1885, but without success apparently (see *American Journal of Science*, vol. xxx. p. 42, and *Astr. Nachr.*, vol. cxiii. p. 228). The same plan has been recently suggested by Fitzgerald (*Astro-physical Journal*, vol. ix. p. 50), and consists in rotating in front of the lens at a known rate a wheel carrying at intervals interceptors of the light falling on the lens. Our apparatus was placed on our meteorograph, and was large enough to occult all of the six large lenses now in use. Our second station is now provided with six cameras, and both instruments were brought into use during the favourable absence of the moon in the first half of August. Unfortunately the nights of August 10, 11, and 12 were completely overcast here, August 9 partly so, so that no records of Perseid meteors seem to show on our plates; but on July 31, August 7, and August 8 each, a

meteor trail from other radiants was secured at both stations, those of July 31 and August 8 showing three or four interruptions, and of August 7 some ten or twelve on the Yale plates. It is, of course, a question as to whether the cosmical velocity can be deduced from these records, and it will be of considerable interest to see whether the results thus derived will agree with the known velocity of the Leonids, if we are fortunate enough to capture any trails next November."

#### ILLUSIONS AND ANOMALIES OF VISION.

AN experimental lecture with the above title was given last week at the Camera Club by Mr. Sheldford Bidwell, F.R.S. This gentleman has long been regarded as an authority on the subject of vision, and his carefully devised experiments, every one of which came off without the least hitch, gave great point of interest to a masterly discourse. As the lecturer had much to say about the phenomena of colour, his words were most attentively listened to, for the followers of what has hitherto been a monochromatic method of picture-making are now, curiously enough, eagerly looking forward to the time when the jackdaw will be able to assume the peacock's feathers.

The lecturer began by asserting that none of our senses was of more importance than that of vision, and none exhibits greater peculiarities. The great Helmholtz once said that, if any skilled optical worker had sent him an instrument so full of imperfections as was the human eye, he should have rejected it as a most faulty piece of apparatus. That great observer also confessed that his own vision was subject to certain disturbances, especially after he had dined well, a condition of things which he attributed to loss of control over the optical muscles. In point of fact, we all see double whether after a good dinner or no, that is to say, we see one point distinctly as a single object, while every other one in the field of view was duplicated. For example, those before him would see at the table one lantern and two lecturers, or *vice versa*.

Optical illusions were of various kinds, and made us make erroneous estimates of height, colour, speed of movement, &c. He would throw upon the lantern screen a diagram, made of four pieces of blue gelatine, which were stepped so that we had a band consisting of different layers, one showing four thicknesses, another three, and so on. These had the appearance of being shaded, so that the whole looked like a fluted column. This was a pure optical illusion. If the divisions were separated each by a fine line, the fluted effect at once disappears.

The next lantern illustration comprised a glass disc with four yellow sectors, cut in their centre with a black band. When the disc was revolved, all details disappeared, and the effect was produced of a yellow disc with a blue ring, the latter colour being complementary to the former. Next the lecturer showed on the screen a succession of light spots moving upwards; but, when the movement was suddenly arrested, the spot remaining on the screen appeared to move in the contrary direction, although in reality it was still.

Mr. Sheldford Bidwell next dealt with the want of achromatism in the eye, and showed several very pretty experiments with a lantern, on the table before him, to illustrate his remarks.

Astigmatism was accounted for by the circumstance that the surface of the eye is not truly spherical, but more like the bowl of a spoon, so that all rays cannot be brought to the same focus. Thus, in looking at crossed lines, either the horizontal ones or the vertical ones seem indistinct, a defect which, in the case of excessive distortion, can be remedied by the use of cylindrical spectacles.

But there is another kind of astigmatism, known as irregular astigmatism, which cannot be corrected by any apparatus. This fault can be detected by pricking a hole in tinfoil and looking through it. The hole will appear to be oval, and, if the foil be brought nearer the eye, it will assume the form of a star with six or more rays, it is due to the construction of the crystalline lens of the eye. The phenomena connected with irregular astigmatism are very curious, and were well illustrated by experiments.

Some visual vagaries depend upon physiological conditions, and one of these is that persistence of vision which causes the image of anything looked at to be retained upon the retina for a period popularly supposed to be about one-tenth of a second; but, as a matter of fact, that period may be either greatly exceeded or greatly reduced, according to circumstances.

The lecturer next showed by one or two good experiments the Young effect, otherwise known as the phenomenon of recurrent vision. A Geissler vacuum tube, mounted so as to turn like a windmill, was followed at a distance of about twenty degrees by a ghost. The same effect was produced on the lantern sheet by a revolving disc, pierced with a hole covered with green glass. The effect ceased if red glass was substituted for the green.

The next piece of apparatus which came under consideration was the toy known as the spectrum top—a top furnished with a card covered with black lines, which appeared coloured when the top was rapidly revolved. This toy excited much discussion when first produced, and it presented great difficulties of explanation, but he hoped to throw some light on the phenomena which it exhibited. The most striking colour in the spectrum top was red, and here we had a notable example of a curious phenomenon. When a bright image is suddenly thrown upon

the retina, it appears to be surrounded by a coloured border, red generally, but, if the light be very bright, it is sometimes blue.

A good way of showing this, for an individual eye, is to take a piece of opaque paper about five inches square, and to make a window of white paper about three quarters of an inch square in its centre. Hold this up to a lamp and shield the eye with a book, now suddenly remove the book and the window will seem to have a red border. Cross the window with a pin, so as to divide the square into two parts, and each part will be surrounded by a red border, the pin, or dividing line, also being red. The black type in a book will also seem red if suddenly disclosed under bright light, and, if a disc and sector be used in front of such a book, the letters will appear permanently red as the disc is turned at the rate of about five revolutions per second. Only lines or dots thus appear to be red, the phenomenon not appearing on an extended black surface. It is due to the sympathetic action of the red nerve fibres and blue and violet sensations not being excited at all, or possibly in a much lesser degree. Some have attributed the phenomenon to want of achromatism in the visual apparatus, but this theory could be disproved by the use of a special form of disc and sector, which he showed and explained.

The well-known effect of negative after-images was then discussed, and the familiar example of a red wafer on a white card, giving rise to a green ghost, was brought forward. It was generally believed that the real image must be stared at for several seconds before the apparition would materialise, but, if a certain condition be observed, the period of staring is reduced to the fraction of a second. The condition was that the retina must have a preliminary rest in darkness; this made it abnormally sensitive. By using a disc and sector of special form any coloured object could be seen in its complementary tint, and by means of an apparatus of the kind, brilliantly lighted by electric glow lamps, the lecturer was able to exhibit the phenomenon in a most effective manner with the help of some specially painted cards. A rose with green petals, a veritable cabbage rose, and red leaves, appeared in the apparatus in its natural garb. A sunflower with purple petals and yellow leaves was, in like manner, translated to a more natural condition. But the *pièce de résistance* was a lady with indigo hair and green face looking at the abnormal sunflower as above described. With a few turns of the disc the lady assumed a more natural colouring, and with this beautiful experiment the lecture closed.

#### THE ADAMSON INCANDESCENT GASLIGHT.

MESSRS. ADAMSON BROTHERS, of Dashwood House, 9, New Broad-street, E.C., have made a very convenient adaptation of incandescent gas to the purposes of photographic portraiture, and an inspection of the apparatus together with some specimens of work produced by its aid satisfies us that photographers have here placed at their disposal a cheap and efficient plan of artificial lighting for the studio.

The system adopted is briefly this: The ordinary supply of house gas is connected up to the apparatus, in the base of which is a gas-holder. A series of four jets, each carrying a mantle, is placed in the concave radiator. One of the jets gives sufficient light to focus by, but, when the full illumination is required, pressure is applied to the gas in the holder, and the blaze of light obtained from the four jets equals a candle power of about 2000.

It is claimed that the exposure required for an ordinary cabinet bust is not more than two seconds, when using any of the quickest brands of plates and a Ross cabinet lens at full aperture.

The standard apparatus will cover a group eight feet across, equally illuminated. As it only weighs 100 lbs., it is capable of being taken out to balls, evening parties, or "at-home work." The apparatus, although working at high pressure, and capable of supplying a number of large incandescent lights, can be supplied with gas from any ordinary tap which may be convenient, so that no new service mains are required to be put in.

The Adamson incandescent gaslight apparatus should be inspected by photographers contemplating a cheap artificial light installation. It is exceedingly simple to work, and, as we have said, the results it yields are all that could be desired.

#### COLOUR PHOTOGRAPHY.

THE announcement that Mr. Cadett would deliver a lecture upon "Orthochromatism" before the Kingston-on-Thames Photographic Society was responsible for a large gathering of members in the Masonic Hall, Sun Hotel, on Monday evening, October 23. Owing, however, to indisposition, Mr. Cadett was unfortunately unable to put in an appearance, but an able substitute was found in Mr. Sanger Shepherd, who for many years has been associated with Mr. F. E. Ives, the inventor of the Kromskop method of colour photography.

To fully appreciate, said the lecturer, the subject of orthochromatism, it was necessary to understand something of spectrum analysis. By means of diagrams drawn upon the blackboard the well-known method of decomposing a beam of white light by means of a prism was explained, an imaginary solar spectrum being mapped out on the board. It is common knowledge that an ordinary or orthochromatic plate is comparatively insensitive to red, orange, and yellow rays, but, by incorporating certain dyes with the emulsion, it is possible, he explained, to manufacture a plate, such as the Cadett Spectrum, sensitive to the whole length of the solar spectrum, or, in other words, sensitive to all the colours to be found in nature. Obviously with a plate of this description it becomes possible to correctly reproduce in monochrome all colour luminosities, provided, of course, that a properly adjusted light filter be used to cut down the action of the blue-violet rays, or, to be more explicit, a screen to equalise the exposure required for all the colours of the painting or subject to be photographed. Such a screen was handed round for inspection, and can be commercially obtained adjusted for use with the Spectrum plate. Mr. Shepherd then proceeded to deal with the more important work for which this particular plate is adapted, namely, the reproduction of colour by photography. Again referring to the diagrams upon the blackboard, he explained the well-known Young-Helmholtz theory of colour vision, viz., that all the colours in the prismatic solar spectrum may be formed from three fundamental or primary colours—red, green, and blue-violet. Any colour to be found in nature may be exactly counterfeited by mixing these coloured lights in various proportions, as, for instance, by blending red and green we produce a yellow, by mixing green and blue-violet we obtain a blue, and by combining all three a white light is formed. This, then, is the foundation upon which trichromatic or colour photography is based. To produce a practical result in colour, three negatives of the subject to be photographed are made upon Spectrum plates, through red, green, and blue-violet filters, each screen being carefully adjusted for use with this particular plate. From these negatives transparent positives are made upon thin, clear celluloid, coated with soluble gelatine containing bromide of silver. This film, which will shortly be placed upon the market with the necessary light filters for making the negatives, is sensitised in a one per cent. solution of bichromate of potash and dried in the dark, when it is ready for exposure to daylight behind the negatives, the celluloid surface being in contact with the negative film.

When sufficiently printed, they are removed from the printing frames and developed in warm water, as in the carbon process. The silver bromide is next dissolved by immersing the films in hyposulphite of soda, leaving transparent gelatine pictures in relief upon an equally transparent celluloid support. After washing out all traces of hyposulphite of soda from the gelatine image, the prints are ready for colouring by immersion in dyes which stain the gelatine relief, the celluloid support, being impervious to the colouring baths, retaining its colourless transparency. The print from the negative made through the blue-violet screen is placed in a yellow dye, the complementary to the fundamental primary blue-violet, this being the colour formed by blending the red and green primaries. Similarly, the print from the negative taken through the green screen is stained a magenta pink complementary to the green, the positive from the negative made through the red screen being immersed in a cyan blue bath, this being the colour obtained by mixing primaries green and blue-violet, therefore complementary to the primary fundamental colour, red. When dry, the three positives are superimposed in perfect registration, and bound up in the form of a lantern transparency, the result being more or less a faithful photograph in colour, according to the amount of care bestowed upon the details of manipulation. It is possible, said the lecturer, to obtain the three negatives with an ordinary camera by using the screens in front of the lens,

and making successive exposures upon three separate "spectrum" plates. The ideal form of camera, however, should be capable of simultaneously making the three negatives upon one plate and from one point of view. Such a camera had been invented and used by Mr. Ives, but, owing to the complicated arrangement of prisms and transparent reflectors adopted to split up and bend the rays coming through the lens to three separate portions of the plate, it had only been possible to manufacture three cameras. These had cost Mr. Ives and himself months of wearisome labour, so that there is little likelihood of this instrument being placed upon the market. He had, he said, been separated from Mr. Ives for some considerable time, but they both, however, had had the subject of a suitable camera before them. While Mr. Ives in the States had taken out patents for a modification of his own apparatus, he (the lecturer) had devised a modification of the camera designed by Ducons du Hauron, which the latter inventor used for experimental work back in the sixties, the improvement consisting of a clever arrangement of coloured diaphragms, by means of which the three exposures could be adjusted at will.

Proceeding to the lantern, Mr. Shepherd threw upon the screen numerous examples of trichromatic lantern slides, made by himself, some being from negatives by Mr. Saville Kent, author of *The Great Barrier Reef of Australia*. These proved to be excellent examples of the process, the pictures of a peacock's feather, butterflies and moths, some orchids, and a group of fish being especially remarkable for their fidelity of colouring.

In response to inquiries, Mr. Shepherd stated that he had seen some excellent landscape slides by Mr. Cadett, who had taken one of his (the lecturer's) cameras to Switzerland. With regard to permanence, the dyes used in staining the tricolour transparencies were stated to be permanent. Asked what possibilities there were of printing on paper, the lecturer described an ingenious printing machine, the invention of a Russian, having for its object the simplification of the registration of the three printings in commercial trichromatic work as applied to a considerable extent at the present time in the illustration of books and magazines, as, for example, the reproduction of *The North-West Passage* by the late Sir J. E. Millais, issued as a frontispiece with *The English Illustrated* of September last. This invention being of no practical interest to amateur photographers, we refrain from entering into details of construction. So far as we are aware, the resuscitated gum-bichromate process is the only method which lends itself to the requirements of photographers in the matter of making colour prints on paper from the three negatives by direct exposure to light. Owing principally to the vagaries of the process and the difficulty of selecting transparent pigments of the required tints, the results cannot always be considered a facsimile in colour. Nevertheless, we have seen many really pretty pictures produced in this way.

### WINDOW TRANSPARENCIES.

Those who have had experience in the making of lantern slides are well aware that however beautiful a glass positive may appear when examined by transmitted light, that is when held up towards the light and looked through, its qualities as so considered cannot be taken as a criterion for judging of the appearance it will have when projected upon the screen by the magic lantern.

To the eye the glass positive, says A. J. H. in the *American Journal of Photography*, so examined, may have everything desirable—crispness, softness, abundance of gradations of lights and rich transparent shadows, but all these may suffer by probation when subjected to a cross-examination in the ordeal of the lantern light.

The knowledge acquired by a long experience in handling lantern slides is the only surety one can have that his judgment is just when decision is given in opposition to the criticism of one who thinks his estimate of apparent virtues in the slide is true and righteous altogether.

With wet collodion the conditions controlling the production of good work, that is, work good for the purpose intended, lantern projection, are more in abeyance to the operator and a uniformity of results more constant. But it is otherwise with the making of lantern slides with gelatine plates. There is not the same assurance that the products will be always the same under the same conditions.

With wet plates, if the collodion is properly constituted and the bath is in good working order, the work becomes almost automatic. However, those qualities which militate against the slides' perfection are by no means inimical to the beauty of results when the positive is intended to be hung up at a window.

Window transparencies may be made either by contact printing or by reduction or enlargement in the camera.

Contact printing is perhaps more generally employed when the negative is of a proper size for framing.

If a mat is employed to cut off marginal portions, care should be taken to secure the thinnest possible paper which shall be thoroughly opaque, otherwise the margins will be hazy. A pad in the printing frame is also necessary to ensure perfect contact of the two surfaces.

It is generally advisable to employ a slow variety of gelatine plate, one in which there is a percentage of iodide of silver; but, if care is taken in exposure with a rapid plate so as not to produce halation or blurring of the high lights, as good results may be obtained.

The exposure when made by contact in the printing frame, should be by gas or artificial light, the frame being held at about eighteen inches or more from the source of illumination. In vignetting, the distance should be increased to five or six feet, so as to avoid harsh shadows around the vignette.

The frame, whether vignetting is employed or not, should be covered with tissue on the outside. Then portions which would be liable to print too intense while the high lights were exposing should be shaded by masks kept in gentle motion, to prevent impression of definite outlines on the plate.

The duration of exposure will, of course, depend upon the character of the negative. On general principles it is best to give full exposures. And here we may say that a rather soft negative yields much more harmonious positives than a contrast negative, inasmuch as vigour, if necessary, may be given to the positive during development by regulation of its constituents and by judicious use of restrainers.

Ferrous oxalate is generally used as a developer, but equally good results may be secured with the employment of the new developers.

Pyro has a tendency to discolour the film, especially if soda is used as an alkali. The addition of a considerable amount of sodium sulphite to the pyro developer, a good washing after development, and clean fixing will ensure bright positives.

If the ferrous oxalate is used as a developer, though it may be antiquated, the operator will be delighted with the exceeding beauty of the positive, which no other mode of development can exceed. Never use even a slightly turbid ferrous-oxalate developer, and always use in connexion with it a few drops of citric acid (ten per cent. solution), and also a few drops of a ten per cent. solution of bromide of potassium. A few drops of syrup (sugar, 1 part; water, 10 parts) will give density and body to a positive and a delightful crisp relieved appearance.

If the ferrous-oxalate developer is not used, the following mixed developer will be found to work well:—

A.	
Hydroquinone .....	80 grains.
Eikonogen .....	80 "
Sulphite of soda.....	1 ounce.
Water .....	32 ounces.
Sulphuric acid .....	1 drachm.

B.	
Carbonate of potassa .....	2 ounces.
Sulphite of soda.....	1 ounce.
Water .....	32 ounces.

C.	
Bromide of potassium .....	1 ounce.
Water .....	4 ounces.

Use equal parts A and B with 5 drops of C.

The ferrous-oxalate developer generally gives results beautiful enough without toning; but, if one desires to tone the transparency any particular colour, any of the well-known toning baths of platinum, gold, uranium, palladium, &c., may be used.

Palladium gives a most beautiful dark purple tone if very dilute bath is used and the action long continued. The writer has made quite a number of toned transparencies with the use of palladium, very dilute, and continuing the action by means of a mechanical rocker for eight or ten hours.

The following method gives beautiful tones:—

First tone with gold (one grain to ounce of water), wash off the plate, and intensify with following:—

Bichloride of mercury .....	$\frac{1}{2}$ ounce.
Chloride of copper .....	$\frac{3}{4}$ "
Hydrochloric acid.....	5 drops.
Water.....	16 ounces.

Rock the plate in this solution until the image is bleached through to the back, then blacken with weak ammonia water.

Russet tones may be had by developing the image up to a certain degree, not full density, then washing off thoroughly and immediately placing the positive before fixing in the above mercurial solution until the image entirely disappears, then washing it most thoroughly and fixing in the hypo.

The hyposulphite restores the bleached-out image. The colour of this image so obtained may be modified farther by toning with gold.

If, after development and fixation, the transparency is subjected to a toning consisting of—

Iodide of iron.....	1 drachm,
Water .....	16 ounces,
Iodine (tincture) .....	5 drops,

a most beautiful opalescent effect is produced, together with a pleasing rose colour of the image. Such transparencies need no ground glass, and may be advantageously employed for ornamental screens for lamps, &c. To prevent scratching of the surface of the film, they may be mounted under plain glass, or the film itself may be hardened by bathing the plate in a solution of formaldehyde:—

Formaldehyde .....	1 drachm.
Water .....	8 ounces.

## ALUMINIUM FLASH POWDERS.

Mr. GEORGE RAU's paper on "Flashlight Compounds," contributed to a recent number of the *American Journal of Photography*, says Mr. A. J. Hahn, in that journal, speaks of the value of aluminium metal in giving an intense actinic light for photographic purposes. Mr. Rau recommends the commercially prepared aluminium silver bronze, which is a very finely divided form of the metal. The bronze is contaminated with a greasy body, which is added, I suppose, to cause the bronze powder to adhere to surfaces. But, however useful as associated with the aluminium as a bronzer, it is not at all desirable in connexion with flash powder, and it will be found best to get rid of it in compounding your flash powder. For this purpose all that is necessary is to heat it in a test tube, or other receptacle, over a Bunsen burner or spirit lamp. So purified, it may be used alone as magnesium is, and projected directly into the flame, giving a much more powerful light and not as annoying fumes. The presence of the grease causes the aluminium powder to clot and prevents its full energy being utilised.

As Mr. Rau suggests, its combination with amorphous phosphorus and barium and strontium nitrates makes one of the most powerful artificial lights for photographic purposes. It is surprising what an amount of energy a few grains of such a combination possesses, and, I think, if ordinary care is used, there is but little danger attending. I keep my chemicals separate, and mix only the quantity needed for the occasion. In this manner one secures the full energy of the powder in its dry state, avoids any risk of caking of the powder caused by the tendency of the strontium and barium to absorb moisture from the atmosphere, and also reduces to the minimum the risk of explosion.

## GEOLOGICAL LANTERN SLIDES.

WE have received the Annual Report and Transactions of the South-Eastern Union of Scientific Societies, from which we take the following extract:—

"During the past year the set of eighty-two geological lantern slides formed in 1897, and illustrating the upper and lower greensand and gault, has been on loan, but only two of our affiliated societies have availed themselves of this opportunity of bringing an interesting local formation under the notice of their members.

"Owing to the apathy that seems to exist amongst most of our societies in matters geological, it was decided at the last Congress to widen the scope of the lantern-slide scheme, and invite contributions towards the formation of sets dealing with—

- "(i.) Prehistoric Man in S.E. England;
- "(ii.) English Wild Flowers, with special reference to forms of capsules and their dehiscences;
- "(iii.) Coast Erosion in S.E. England;
- "(iv.) Marine Animals and Plants as transparent lantern slides (according to Dr. H. C. Sorby's method described in *Nature*, March 31, 1898, p. 520).

"It was hoped that the widening of the scope would awake a greater amount of interest and support, but so far the appeal has not met with much response. Two valuable offers of assistance have been received. Mr. F. V. James, F.S.A., of the Museum, Maidstone, has kindly volunteered to organize the set dealing with 'Prehistoric Man,' and, by the special knowledge gained from his own researches and the materials already at his command, the success of this set should be assured. Mr. James will be glad to hear from any members who may be willing to co-operate with him by contributing slides or information dealing with the subject.

"Mr. Stephen Horsley, St. Peter's House, Canterbury, President of the East Kent Natural History Society, has kindly consented to take charge of set ii., dealing with our English wild flowers, a subject to which he has devoted much time and labour. The value of Mr. Horsley's assistance will be best gauged by an extract from one of his letters: 'I have thought for some time that one could not do better than make over one's scientific slides to a Society such as ours while one is alive; for, except in special cases, it must be very difficult to know what to do with such slides after the death of the owner, unless they are of sufficient importance to be definitely left to a society or institution in one's will. I have two or three hundred slides, many of them coloured, which I have made from the actual plants, and I will go over them and make out a list of those that would be useful to the Union, and present them to it.' It is to be hoped that Mr. Horsley's generous offer will find many imitators. Serious illness has, unfortunately, interfered with his intentions, but one set on which he is engaged deals with our local orchids, each kind being represented generally by several slides, showing (i.) general growth, (ii.) root, (iii.) flower, (iv.) details of flower, (v.) microscopical details of anthers, rostellum, pollinia, &c. In view of the highly specialised structure of the Orchidaceæ, and their wonderful adaptations to insect fertilisation, this set should prove most interesting and instructive. Mr. Horsley also contemplates a second set, dealing with the fruit and capsules of common plants and trees, and will welcome any offers of assistance towards rendering either set more complete.

"The subject of 'Coast Erosion' is a most important one, and should receive special attention at the hands of those societies whose situation gives them the opportunity of noting the wear and tear of our cliffs.

There is no lack of material for an excellent set of slides, illustrating not only the results, but the agencies at work in shaping the contour and profile of the coast-line. The appeal for assistance in this direction has not been very fruitful, but the Photographic Secretary is hoping to secure offers of help during the coming summer.

"No contributions towards set iv. have hitherto come to hand. Dr. Sorby's method of preserving marine animals and plants as transparent lantern slides is probably known to few, but all necessary information is given in the article in *Nature* already referred to.

"The work of the photographic section of our Union may be made most valuable if the secretaries of the various societies will only give it their hearty co-operation by getting one of their members to act as local correspondent, so as to bring the photographic Secretary into direct touch with the local Society. In this way only can the slide scheme be made a complete success, and the life of the section be kept healthy and vigorous.

"Many of our members are interested in photo-micrography, and I would suggest that this be added to those subjects to which attention has been called in this report."

## FLASHLIGHT PHOTOGRAPHY.

At a meeting of the Leeds Camera Club, on Wednesday evening, October 25, a lecture and practical demonstration of flashlight photography was given by Mr. J. W. Wade, of the Manchester A.P.S., one of the most experienced and best-known workers in this interesting branch. Whilst not advocating flashlight in preference to daylight, Mr. Wade showed it was a most useful adjunct, for it enabled certain work to be done which otherwise could not very well be obtained. Perhaps its most useful application was in portraiture, especially theatrical and fancy dress costumes, which generally had to be done by artificial light. The lecturer showed that, in combination with daylight, effects could very often be produced that were unobtainable without its use. Most of the best work in the French school of photographers in portraiture is done in this way. Using the magnesium light alone, the same effects were seen by using two or more lamps, suitably arranged with respect to the sitter. The principal light should not be in front of the camera, but a little to one side, whilst any lamp placed behind the sitter should be screened by tissue paper in order to diffuse the light. The various forms of lamps to use, and their different features, were clearly dealt with, and the position of the sitter, the background, camera, &c., indicated. For the photographing of flowers he strongly recommended its use.

The lecture was illustrated by over a hundred lantern slides, the product of many years' work, and the result of many trials and much tribulation, although the resultant pictures were many of them very beautiful.

The lecturer afterwards demonstrated the process by photographing a sitter, a lady model, in a classical Greek dress, whom he had brought with him from Manchester, as well as one of the members (Mr. Homburg), who was dressed in a most original and effective Roman costume. Much interesting and valuable information was given by Mr. Wade, and he, along with his sitters, were accorded the hearty thanks of the members, the room being crowded.

## A REVOLVING DEVELOPING DEVICE.

THIS is the invention of Mr. W. F. Crawford, and consists of a pair of discs mounted upon a horizontal axis, and having their inner surface grooved radially in such a manner that the grooves of each disc are exactly opposite the grooves of the other disc, and are thus capable of receiving one or more photographic plates or carriers in or upon which the films, plates, prints, or the like, can be disposed. This apparatus is suitably supported over a trough of convenient shape, and so that practically the lower half of the discs is immersed in the liquid contained in the said trough. Means are provided for rotating the said discs and for the supply of liquid, and also arranged for the easy removal of the discs with their contents from one trough to another where required. This apparatus consequently forms a very effective and simple device for developing, fixing, rinsing or washing plates or films, or for toning, fixing, and washing prints.

Mr. Crawford's description is as follows: In the drawing of figs. 1, 2, 3, 4, 6, 7, 8, *a* indicates the trough internally, half circular, of a slightly greater diameter than the discs; *b*, the discs; *c*, the shaft or horizontal axis; *d*, the milled buttons (only one shown) for revolving the apparatus by hand. In place of milled buttons ordinary handles may be employed, *e*, the film or plate-carrier; *f*, the radial sector. The discs, *b*, connected by the shaft, *c*, are shown in fig. 8 as supported in bearings in the edges of the trough, *a*.

Each disc, *b*, has at least one peripheral groove, *k*, in which is located an elastic ring, *l*. This ring is of a diameter slightly smaller than that of the discs, so that it will remain turned over towards the inside or towards the outside of the groove, according to the position in which it is placed by the operator, and, moreover, the ring can be turned over partly in one direction and partly in the other.

The discs, *b*, are radially grooved, as shown in fig. 8. The grooves of each disc are arranged exactly opposite the corresponding grooves of the other side, and the photographic plates and carriers, *r* (figs. 1 and 2), and radial sectors, *c* (figs. 6 and 7), are arranged to slide in these grooves.

The apparatus shown in fig. 8 is intended to be revolved by hand by turning the milled buttons, *d*, and in this manner an effective developing, toning, fixing, or washing of the plates, films, prints, or the like, can be obtained.

The radial sectors (figs. 6 and 7) may be used to produce sectional chambers between the discs by placing them with the tops all facing in one direction, to accommodate plates, films, or prints during the processes of developing, fixing, toning, or washing. The sectors may consist of pieces of perforated zinc, or other suitable metal, bent into the form shown in section in fig. 6.

The carrier shown in fig. 1 is preferably of a double form, as shown, and may be used either for the largest size the machine can take, or smaller plates, films, or prints, which are inserted therein sideways within wider or narrower curved edges, as shown in the drawings.

In fig. 9, *A*<sup>1</sup> indicates a trough constructed of tin or other suitable metal, similar in shape and construction to *A* (fig. 8), with lugs or brackets, *m*, to support the spindle by its smaller bearings, *u*, shown on the milled buttons, *d*, during the process of automatic washing of plates, films, or prints, which operation is performed by the impact of the washing water on the plates or carriers causing the whole to revolve. *H* is a sliding regulator to govern the exit of the washing water.

In fig. 10, *A* indicates the trough, as in fig. 8; *B*, the discs; *C*, the shaft. The ends of the shaft, *C*, enter slots, *e*, in the side of the trough, so arranged that the shaft is merely kept in place, and the discs are entirely supported by being suspended by the driving bands, *f*, from the pulleys, *g*, on the horizontal shaft, *h*, of the motor, *i*.

The apparatus (fig. 10) is intended to be operated automatically by the water employed in washing the larger sizes of the plates, films, or prints.

The motor, *i*, which may be a paddle wheel, turbine, or other convenient form of motor, receives the water from a jet or otherwise, and is set in motion thereby, and as the discs, shaft, and contents are suspended by the endless bands, *f*, from the axle, *h*, of the said motor, the apparatus is revolved in accordance with the revolving of said motor, and the washing of the plates, films, or prints, is effected automatically. The plates, films, or prints are kept in position by the perforated radial sectors shown in figs. 6 and 7, or may be attached to the carriers, *r*, or, in the case of plates, may be slid into the grooves without carriers or supports.

For ordinary developing, fixing, and toning processes, and for slight washing or rinsing, I make use of the apparatus shown in fig. 8. Having placed a sufficient quantity of developing solution in the trough, *A*, and inserted the plates in the radial grooves of the discs, *b*, I then turn the rubber strips or rings, *l*, inwards, which immediately and effectively prevents any of the plates from slipping out as the discs revolve. I then cause the discs and contents to revolve in the trough until the

plates are fully developed. The discs are now lifted out of the trough and placed in the washing trough, *A*<sup>1</sup> (fig. 9), and automatically washed for a sufficient time. *A* (fig. 8) is emptied of developer, washed, and charged with sufficient fixing solution, whereupon the discs are immersed and revolved in it until fixation is completed. The discs are finally removed and placed in trough, *A*<sup>1</sup> (fig. 9), where they revolve by the impact of the water on the plates or carriers from a tap or other orifice, until they are completely washed.

The manipulation of films and prints is substantially the same as for plates, but the films and prints are first inserted in the carriers (figs. 1 and 2), or they may be placed in the sectoral chambers formed by placing the radial sectors, *c*, in position.

The apparatus shown in fig. 10 is designed for plates, films, or prints of a larger size than half-plate, and is driven automatically by a constant flow of liquid which, after revolving the motor, falls on the perforated radial sectors, plates, or carriers (figs. 6 and 7), which are placed in the grooves of the discs as described, percolates through them, and falls into the trough, and escapes therefrom by a siphon or suitable orifice.

### LANTERN SLIDES PICTORIALLY CONSIDERED.

BEFORE the Borough Polytechnic Photographic Society on October 25, Mr. John A. Hodges, F.R.P.S., delivered a lecture on "Artistic Lantern Slide-making." He said the question of the artistic rendering of lantern slides had given rise to much controversy, and probably would continue to do so, although he certainly thought that the subject had been unfairly dealt with by critics, who he feared had been wilfully blind to any redeeming qualities in this phase of photography. He did not pose as an advocate of unrestrained "faking" over the unaided production of chemistry and light, but necessity was a stern taskmaster, and, when one is brought face to face with difficulties that may be overcome by skilful treatment, surely it would be worse than folly not to recognise that fact and take the fullest advantage of it. Nature was not necessarily art, therefore a photographer may reproduce nature *minus* art; the skill of the artistic photographer consisted in so subduing or emphasising the purely photographic result. The artistic photographer, in making his prints, resorted to sundry methods of "dodging" to modify these defects and produce a definite result. The lecturer then proceeded to describe his method of local control which could be applied to the production of lantern slides. A thin but well-graded negative was obtained, in which the high lights just lacked the vigour necessary for producing a good slide. Intensification, he said, would not to any appreciable extent alter the scale of gradation and practically the density was increased proportionately throughout, whereas the true remedy, in order to produce a more pleasing pictorial effect, was to slightly alter the relative values of the various tones. He did this in the following manner: A piece of very fine and evenly ground glass of the size of the negative was bound up with it, the ground surface being outward. The negative is then placed in an ordinary retouching desk and the high lights and lighter tones of the picture strengthened. Elaborate working up was undesirable. For introducing half-tones in masses, for subduing depth of shadow, and generally when dealing with large areas, he thought the best medium was plumbago or black lead, very finely powdered, applied with the finger-tip, and worked down with a stump. High lights could be accentuated, strengthened, or even introduced with black-lead pencils of different grades, B and BB being the two most useful numbers.

We have received from Mr. John Piggott, of 117 & 118, Cheapside, E.C., his supplementary list of lanterns, in which there are mentioned many cheap items of optical projection apparatus.

We are asked to note that Messrs. Newton, of Fleet-street, have just received a very fine lot of negatives of the Transvaal and neighbourhood, from which they are making lantern slides. These are in addition to those they have already published.

Mrs. R. B. LODGE, of Enfield, gave a very interesting lantern lecture at the Bedford Y.M.C.A. Hall, in connexion with the Beds Natural History Society, on Wednesday, October 25, entitled "British Birds at Home and Abroad." A very large number of excellent views were shown depicting the birds in their haunts, nests, &c. The subjects dealt with included: "The Sea Birds of the Farne Islands," "On the Shores of the Wash," "Bird Life in the Broads," "British Birds in Dutch Marshes," "Bird Life in the Spanish Marismas," and "Suburban Birds." The lecture was much appreciated.

THE Hon. Sec. of many a photographic club often wishes to call the attention of members to such little items as "Subscriptions are now due," "Members are invited to bring their lady friends to the next meeting," &c. Here is a hint which will enable him to write his notice on a bit of clean glass and then pass it through the lantern. Hunt up an inkstand which has dried up or is at least too thick and muddy for ordinary use. To this add a few drops of thick gum-water. Mix well, and you will find you can, with a little patience and a fairly soft broad pointed pen, write as easily with the mixture on glass as on paper with ordinary ink.—*Photographic Scraps.*

### LANTERN MEMS.

THE Inaugural Evening of the Lantern Section of the Royal Photographic Society was a distinct success, and the introductory address by Mr. J. J. Vezey, F.R.M.S., lucid and convincing. He put forward the claims of the optical lantern in connexion with photography, and emphasised it afterwards by having projected on the screen a series of lantern slides that were typical of artistic conception and excellent manipulation. It is seldom that I have had the pleasure of seeing so many beautiful archæological and architectural subjects at one sitting, and Captain C. E. Gladstone, R.N., is to be congratulated on the results of his careful selection of positions and lighting of the subject when taking the negatives.

\* \* \* \* \*

THE title of the lecture, which Mr. Vezey made very interesting, was "Some Mediæval Towns of Germany," and, as pictures, many of the photographs shown were almost faultless. The eleventh and twelfth-century buildings were very quaint, and the scenery, with houses built on artificial islands in the water, most curious. Some of the most successful slides were the views through archways, and of odd corners of the old cities, crypts of cathedrals, and beautifully sculptured doorways. In all, some 120 slides were shown, and very few were without some distinctive merit in the matter of treatment, besides being records of architectural beauty.

\* \* \* \* \*

IT is to be hoped that the suggestion of the lecturer will be carried out, that the R.P.S. will continue the work started by the Lantern Society, and the monthly lantern nights will bring together those interested in lantern work for their mutual benefit and advancement, and also add to the membership of the Society. With a Society so well established the lantern section should always have reasonable support, and those lantern workers who are not members of a photographic society will benefit by being enrolled in the parent society devoted to the black art.

\* \* \* \* \*

WITH projection microscopes, polariscopes, spectrum apparatus, and photo-chromotropes to work with, many interesting evenings are in store; and even the erstwhile much-abused dissolving-view apparatus will, I venture to predict, furnish an agreeable change, if not a record entertainment, for of recent years many very beautiful dioramic effects have been produced that can be exhibited with such

exactness of register as to produce realism, by apparatus designed to give perfect optical and mechanical control, and mostly without further assistance than one well-practised lanternist. Many of these slides have photographic bases, and therefore should be not only permissible but welcome in a photographic society.

\* \* \* \* \*

IF one can take as Gospel truth what one finds in the lay papers respecting the money made by animated photography, not only the proprietors of the films but also the "subjects," when they happen to be the principals in a boxing match, are to be congratulated, for beyond a *small* matter of 3000*l.* paid for the privilege of biographing the event, a third share in all future earnings of the film is stipulated for, and as the result of one contest the victor is stated to have netted over 6000*l.*, while the loser's share was over 2000*l.* It appears that a film fifteen miles long is on its way to England, and will shortly be exhibited at the St. Stephen's Hall, Royal Aquarium, and, if the results to Messrs. Jeffries and Sharkey are proportionate to that just referred to, one almost wishes it had fallen to the lot of a humble servant of optical science to have been attached to the boxing science instead, for the said film is reported to be of the estimated value of 100,000*l.*, and the boxers respectively are expected to realise 37,000*l.* and 33,000*l.* This is beyond the dreams of avarice. Who would not be a boxer and say, "Hail Columbia!"

\* \* \* \* \*

IT is quite a revelation to some of the public, and especially gentlemen getting up lectures to be illustrated by lantern slides, that there is such a thing as a law of copyright, and it is quite amusing to hear the innocent way in which they calmly ask for such-and-such a picture or portrait to be photographed on glass. The climax was reached the other day when a gentleman took into an optician's shop the frontispiece to Rudyard Kipling's poem of the "Absent-minded Beggar" for a slide to be made by the day after to-morrow. He was asked if he had permission *in writing* from Mr. Caton Woodville, the artist, or the proprietor of the copyright, and said, "Oh, that's all right! I have permission to recite the poem." When told it might cost 200*l.* if done, as injunctions in Chancery are expensive matters, he opened his eyes rather wide. It is well for all lanternists to understand that, if a slide is used for profit, even if photographed by themselves, they lay themselves open to an action at law.

\* \* \* \* \*

THE demand for slides connected with the war in South Africa is growing apace, and Messrs. Newton are publishing some good reproductions of the stirring events as depicted in the illustrated journals, besides having photographs of some good scenery. Mr. J. H. Steward has received direct from South Africa a fine collection of natural photographs, which embrace places in the Transvaal that have not hitherto been obtainable as lantern slides; they number some sixty slides or so, and are published by the authority of the Cape Government Railways. War is a dreadful necessity at times, and when

one remembers, as I do, the fine body of officers and men that were reviewed recently at Wellington Barracks, and now learn from the papers that some of them have been struck down by shot or shell, it seems as if personal friends had been lost, for I was in touch with so many of them in business matters, as an officer to be of use nowadays must be scientific. My advice to those who have pictures applicable to lectures on the war is, publish them, for the martial spirit of the country is aroused and everywhere patriotism is rampant.

G. R. BAKER.

### LANTERN RADIANTS.

[A Paper read before the Photographic Club.]

THE radiants which I bring before your notice are only those of a useful and commercial nature, as I do not think that a description of obsolete apparatus would serve any good purpose. Those to which I shall allude are the petroleum lamp, acetylene, the incandescent Welsbach mantle, limelight, and the incandescent and arc electric lamps.

*Petroleum.*—The first practical lamp was that introduced by our American friend, Mr. Marcy, of Philadelphia, who worked out a form of lamp which, up to the present day, is embodied in nearly every petroleum lamp and lantern. The "Sciopticon" is the name of the lantern, and it was introduced into England by Mr. Woodbury. It has two flat wicks about two inches wide and parallel to each other, having an air space between them. The edges of the wicks are placed towards the condenser. A very good light is given off, and the lamp is about the coolest oil lamp working.

Other lamps have been introduced, all adhering to the same size of wick, but having, instead of two, as many as three, four, and even five wicks. Of the three-wick lamps, Newton's Refulgent is the best in my opinion. It was introduced to obviate the dark space which was always noticeable with the two-wick lamp, owing to the dividing space. Stock's patent lamp, a four-wick lamp, cannot be beaten for light-giving properties, construction, and working, amongst its kind. It differs from the old form, both in the body or combustion chamber, and in the chimney. The combustion chamber is formed so that the incoming air is brought into contact with the flame in such a manner as to produce, in conjunction with it, the best result, and is provided with an adjustable reflector for collecting and bringing as much light as possible into focus. Provision is made for the extension of the chimney mechanically. This is very important in practice, as on first lighting a lamp everything is cool, and the evaporation of the oil is much less than when the whole lamp is heated. Hence one must either turn the wicks down, or gradually lengthen the chimney as the lamp gets heated. The latter is the better course. The light is increased, and one has only a single knob to turn in the chimney, while to tamper with the wicks, which are four in number, each requiring nice adjustment, takes a considerable time, with very often a poor result. The chief point in favour of petroleum lamps is that petroleum can be purchased nearly everywhere, and it is always ready for use. There is little or no danger, and it gives a very fair light with the average commercial slide. Five-wick lamps were introduced, but were found difficult to manage. The combustion was bad, and very great heat was given out.

*Acetylene.*—This gas gives a very white and intense light compared with petroleum, although I think the quantity is about equal. It is generated with little trouble, and is easy to manipulate. There are many very good generators now obtainable, notably those of Messrs. Thorn & Hoddle, the Abingdon Safety Generator Company, and the Bon-Accord Acetylene Gas Company. Each of them has features of its own, but all are suitable for lantern purposes. Mr. W. Tylar, of Birmingham, has specially constructed an exceedingly portable form, which takes the place of the petroleum lamp and fits in the lantern body, taking up no more space, and reported to give satisfactory results. There are, however, disadvantages about acetylene, and one is the corroding of the burners. Great improvements in these have lately been made, and without doubt this fault will soon be overcome with the purification of the gas and other improvements which are being effected in the generators. Another

difficulty is that, unless special care be taken to make all joints sound, small leakages will soon make themselves known by the strong and peculiar odour of the gas. Acetylene is, like all other hydrocarbons, perfectly safe until oxygen combines with it, but in its simple form may be considered without danger.

The Welsbach mantle has been before this Club upon more than one occasion. I have been experimenting with it to see what its real value as a radiant for lantern work might be, but up to the present can only look upon it as a convenient radiant for places such as drawing-rooms, with a disc of six to nine feet. I have also put the mantle in lantern for enlarging work, where it has given every satisfaction.

I have recently been experimenting, in conjunction with Mr. Henry Howell, of the Welsbach Company, and have brought up the burner constructed by him to show you. To obtain better pressure I have introduced a cylinder of condensed gas, which gives a pressure much higher than can be had from the house supply. Unfortunately, one cannot yet rely upon the compressed gas, owing to the iron which it contains depositing upon combustion upon the mantle, quickly ruining the latter's incandescent properties.

With a cylinder of coal gas kept standing for three months, the mantle will go in a few minutes. House gas can be used with a mantle for an average of one thousand hours. We were promised stronger mantles, which would stand the increased pressure of the compressed gas, but I find that there is an almost daily shrinkage of the mantle against the burner, and sooner or later it splits. It should be seen that no flame is proceeding above the mantle, turning down the gas until this is remedied. Its illumination is about equal to that of the oil lamp, but its drawback is that its area is so great.

Limelight is obtained by the incandescence of a white-hot lime. There are several forms of apparatus with which to bring about this object, and one of the most simple is a jet named the Safety Jet, or Blow-through Jet. For the reason for the name "Safety" we must go back to the early days, when the gas was stored in bags, and there was little to prevent the gases from becoming mixed. To obviate this, the tubes conveying the gases were entirely independent one of the other, the two gases issuing from two separate orifices, the house gas from the larger orifice and the oxygen from the smaller, the latter blowing through the flame of the house gas. Such a jet is upon the table. I have also another jet in which the orifices, instead of being separated, as in the last case, are connected by a Y piece. This form ensures the issue of both gases at the same angle, the oxygen nipple being in the centre of the coal-gas flame. By this means one gets a more concentrated flame, and, I think, as a rule, a little better result than that given by the former. The best distance for the lime for burners of this description is from  $\frac{1}{2}$  in. to  $\frac{3}{4}$  in., or, better still, for the operator to look at the reflection of the lime in the condenser and to draw the lime to and from the burner until he sees no black spot. There are other forms of blow-through jets, but I shall speak of those under the heading of injector jets.

The injector jet is a jet in which the gas, at a high pressure, is made to force or inject gas at a lower pressure. As an instance, I take the form of jet where the Y piece connects the two tubes, and by inserting a nozzle in the Y we shall at once form a simple injector; but, in practice, this form of jet does not give the best of results. But, if the principle is employed in a different manner, as, for instance, in the Manchester Oxygen Co.'s jet before you, the principle of injection is more fully developed.

I have installed in a London music hall this form of jet for stage lighting, giving the utmost satisfaction, and, although they were at first suspected, they have been no trouble whatever, and are now running perhaps better than at first, owing to the greater confidence and practice of the operators.

In using this jet for biunial lanterns there is a difficulty in dissolving unless a very strong pressure of house gas is obtainable. The difficulty is due to the snapping or small explosions in the mixing chamber in dissolving. I attribute this to the high pressure of the oxygen and the low pressure of the house gas in the tubes from the burner to the dissolving tap. As an instance, say that a tube eight feet long filled at normal pressure with coal gas, and another tube eight feet long filled with oxygen at an atmosphere

pressure, you will have two volumes of oxygen to one of coal gas, and this is exactly what you get in the ejector jet from the dissolver. You cut off the supply in these proportions, hence the oxygen expands to form an explosive mixture in the chamber of the jet and explodes.

In working this jet I find it quite different to the blow-through jet. In the blow-through jet more coal gas is wanted, but with the injector jet you usually have too much, and it requires cutting off. In turning off the jet it is always best to turn on the house-gas tap full, then turn off the oxygen, and finally turn off the house gas. I have no doubt that, if a dissolver were made to work on this principle, it would remedy the failing I have described. While upon the subject of injector jets, I have here a separate injector with which any mixed jet can be used. It is only necessary to put a larger nipple upon the jet, and you can use your house gas.

The use of the injector in conjunction with the cylinder of coal gas and the house gas will be found very useful for increasing the pressure of the house gas. Instead of using compressed gas altogether, only a little need be used, and the higher pressure obtained at a minimum of expense.

*Electric Light.*—My experience has been entirely with the direct current arc light. In my hands it has been very simple and easy to work, and, with a lamp under perfect control and with the carbon holders both insulated, there should be little trouble. I think that electricians are likely to be too lavish in the quantity of current for lantern projection, thinking, doubtless, that what suits the kinematograph will suit the ordinary lantern. Sixty volts is what will usually be found best suited for the purpose. R. R. BEARD.

Mr. Alex. A. K. Tallent supplemented Mr. Beard's remarks upon the electric arc light for lanterns to the following effect: The idea, he took it for granted, was to get an illuminant as compact for lantern projection work as possible. This was easily obtained with a direct current for the reason that the soft core of the positive carbon soon gets white hot, forming a crater, and remains so for as long as the current is passing. It really forms a spot of intense brightness apart from the illumination proceeding from the surrounding portions of the pencil of carbon. These conditions, so easily obtained with the direct or continuous current, are not so readily secured when the current available is of the alternating kind. In the ordinary way the same effects previously described tend to take place with alternating current, but at each carbon, and consequently with a decreased brilliancy. It is clear, then, that the conditions must be modified so that the light is confined to the one carbon. It was found that this was best secured by having a soft-cored carbon for the top, and that core an eccentric one. Mr. Hepworth brought out such a carbon, the core running not through the centre, as is usual, but towards one side. This carbon is placed in the lantern with its core nearest the condenser. There is some difficulty in getting these eccentric carbons, but in such cases, as it not at all follows that they must be of circular section, one can take a centrally cored carbon and face it off. Another substitute can be made by filing a groove lengthwise in an ordinary carbon. This may also be done with the eccentrically cored carbon, laying bare the soft core almost. The bottom carbon may be one of the solid kind, and of smaller diameter than the one we have just dealt with. The result is that it does not reach that degree of heat which makes the core of the top carbon of a white heat.

Another factor which favours us is that the core of the top carbon is more or less protected from draughts. It will be found that the lower carbon under these conditions burns to a point like the negative direct current carbon, and if properly placed it does not obstruct the light emitted by the upper carbon. In arranging the carbon of the lamp for lantern projection, it must be remembered that one does not wish the light to proceed in all directions, as in the street electric lamp, where the carbons are in line. The light must be sent out to the condenser. This is arranged by stopping the lower carbon in advance of the upper, and canting them both at an angle backwards from the top. By putting the lower carbon in advance of the upper carbon we form the arc in front of the upper one, and largely prevent its rotation, so that our point is partly gained. By

canting the lamp we still further bring the arc to the front, but the correct angle must be determined by trial. Mr. Tallent projected, by a system of lenses, an enlarged image of the arc upon the screen, to show the effect of the dispositions described. He also showed a piece of apparatus of the nature of a pinhole camera, intended for the observation of the arc. It takes the shape of a small tube, at one end of which is the pinhole, and at the other a ground-glass screen ruled in cross lines. The pinhole end is placed about half an inch from the arc, and its image observed upon the screen. After once adjusting the carbons and getting the best light, any deviation would be noticed on the ground glass by the position of the arc's image on the line, and corrections and adjustments could be easily made. If the carbons be kept at a fixed relationship, one can be sure of the constancy of the light, which for many things is most desirable.

#### LONG AND SHORT-DISTANCE PROJECTION LANTERNS.

It will be manifest that an instrument more especially designed for use in a private dwelling-house would be practically of little utility for projection purposes in large halls or theatres. Therefore, in the selection or purchase of a lantern, it is important that some consideration be bestowed upon the special purposes for which such lantern will ultimately be required. In the event of a lantern being desired for home use only, the optical arrangements will differ materially from such as would be required in a lantern designed more particularly for long-distance projection.

In the latter, not only are long-focus objectives required, but the condensers to converge the pencils or rays of light passing from the lime ball through the picture or slide must also be of longer focus than would be the case were an objective employed for moderately short-distance working. It is just here where much misconception exists among amateur lanternists, the belief being very general that all that is necessary to adapt any well-constructed lantern for use at varying distances from the screen is the substitution of long or short-focus objectives in proportion to the distance it is desired to work from, whilst the equally important bearing which the condenser plays in such projection is entirely overlooked, for a condenser that yields admirable results in converging rays of light when employed in conjunction with a five or six-inch objective will fail to give anything like results in connexion with, say, an objective of twelve-inch focus.

Nearly all the trade or stock lanterns supplied by even our best opticians are fitted with what may be termed short-focus condensers and short-focus objectives, the idea, doubtless, being to adapt same more particularly for short-distance working, such as would be required in dwelling-houses, where the aim is to obtain the largest possible size of picture within the shortest distance from the screen. Such lanterns will be found, in all likelihood, to be fitted with double plano forms of condensers of about four inches focus when measured from the centre of the combinations, or three inches from the back lens to the lime ball when the jet is finally adjusted in its proper position for focussing the light upon the screen, with the aid of, say, a five or six-inch objective.

Now, there is really no difficulty in converging all the rays of light from a spot of, say, three-quarters of an inch (such as an ordinary lime cylinder yields with a good mixing jet at fairly high pressure) at a distance of six inches in front of the condenser, and such an optical arrangement will be found to work admirably, but the moment we come to change the six-inch objective for one of much longer focus—say, twelve inches or more—we introduce a radical change in the whole optical arrangements of the lantern. The jet which has hitherto been placed in its best position for the convergence of the rays at a distance of six inches in advance of the condenser will require to be placed considerably nearer the back lens of the condenser to converge the light at a greater distance than six inches in advance, and, as we have seen already, that, to gain the necessary amount of convergence with the short-focus condenser that is being employed, a distance of only three inches is available as an angle of incidence for the rays to spread over the face of the condenser, not only would the jet or lime ball be too near the back lens of the condenser, and hence very liable to fracture the same, but the corners of the picture would be improperly lighted. It therefore follows that, if we are to use long-focus objectives, we must provide suitable condensers, in order to so converge the light that they may be employed to their best advantage, and this is a most important point when selecting a lantern for long-distance projection. Strange to say, many of our salesmen with opticians, and who are supposed to be expert in lantern matters, are seldom found possessing a knowledge of this fact.

Another important matter in connexion with long-distance projection is the diameter of the back lens of the objective. In short-focus lenses, say, of about five to six inches, the diameter of the back lenses is generally found to be about one and five-eighths of an inch. Now, with short-focus condensers, it is quite easy to converge all the rays from a lime ball into a cone of such diameter at a distance of six inches in front of the

condenser, but, the moment we attempt to converge the rays into a similar cone at varying distances in advance, so soon do we find our difficulties beginning, and a point is soon reached when lenses of the diameter above stated (viz., one and five-eighths of an inch) will fail to grasp or pick up all the rays transmitted by the condenser. At this point such an objective will begin to lose light, and therefore, with the longer focus objectives, there must be provided larger diameter of objectives. Up to eight or nine inches in front of the condenser, objectives of two and a half inches will be found ample, but, when much longer-focus lenses are employed as objectives, then their diameters must likewise be increased, and every aid rendered by the employment of suitable longer-focus condensers.

In the early days of the lime light, when we had nothing like the pressure we have at present from gas cylinders, the practice of working so as to project as large a disc as possible from a short distance was quite a necessity so as to get the utmost amount of illumination, and no doubt this old practice has done much to foster short-distance projection even in the present day, but limelight procedure is quite a different matter now to what it was twenty-five years ago. Compressed gas has enabled improved jets being employed, and now, with suitable apparatus, it is possible to project a picture in a brilliant manner, which at that early period was practically impossible.

The advantages of long-distance projection over short-distance working are many, not the least of them being the comfort to an audience provided by their having no interruption in the form of the emission of light from the lantern placed in advance of them.

Speaking generally, but few schoolrooms or country halls will be met with that do not contain a floor space of at least fifty feet, and, whenever such have to be used for lantern entertainments or lectures, there is no better size of screen to employ than one of twelve feet or thereabouts, and to use a twelve-inch objective at a distance of about forty-five feet, which will yield a suitable sized picture on the twelve-foot sheet.

By working from the back of the audience, an operator can always depend upon less interruption than is the case when he finds himself surrounded and cramped by numerous inquisitive onlookers; and, further, he is enabled to take more licence with the doors and ventilators of his lamp than is possible when working in front of the audience.

As to brilliancy of light, if a good mixing jet be employed, there need be no anxiety; of course, the same results are not obtainable with a blow-through, but, then, no operator of experience nowadays ever thinks of employing such in long-distance projection. A well-packed mixing jet with a bore of  $\frac{3}{16}$  or  $\frac{1}{4}$  inch will yield all that is required in the way of light, and at the same time not overheat the lamp, as larger bores are very liable to do.

During recent years there has been a distinct movement on the part of lantern-makers to reduce the size of the shells in both the single and double forms of lanterns, until it is safe to assert that the thing has been ridiculously overdone. There may, indeed, be no need for such clumsy shells as were in vogue thirty years ago, but a lantern of good size will work much cooler than some of the small-sized articles now so prominently on the market, and it by no means follows that for single lantern projection wooden-lined bodies should be employed, these wooden bodies keep in the heat that would otherwise escape; a metal body will work cooler than a wooden-lined one, in so far as being less destructive to condensers.

The theory that light is lost by using long-focus condensers may be entirely discarded, any loss of light arising from the jet being drawn further back when long-focus condensers are employed is fully compensated for by the better class of jets now in use, and they are easily pushed to a greater extent without hissing than was formerly the case.

T. N. ARMSTRONG.

#### BOGUS WAR AND OTHER PICTURES.

THE extract from *South Africa*, given in these pages recently re the manufacture in Paris of war photographs to order, is very interesting. Stay-at-home photographers can have but little idea of the very large number of fraudulent photographs that are in existence both at home and abroad.

The first cinematograph pictures I ever saw of a war in actual progress were at the large music hall in Liverpool some years ago. The hall was crowded nightly by an enthusiastic audience, who applauded and encored the pictures of the Greeks and Turks in mortal combat in such a hearty manner that it would have made a happy man of the sickly monarch of the East had he been there to witness it. Knowing well the difficulty of photographing, let alone cinematographing, like pictures at such close quarters, I wrote to a well-known authority, and asked him if these war pictures were genuine. He replied that he "thought" they were. I, however, had my suspicions, but let the matter rest until I went on the Continent. There I made inquiries, which resulted not only in my getting into the circle of workers who produced such pictures, but I actually assisted in producing many other bogus war scenes. We are now told that certain Englishmen have gone out to the Transvaal with cinematographs, and I, with many others, am anxiously awaiting their results. I do not doubt for one single moment that excellent pictures, showing the movements of the British army will be obtained, but I shall

view with very great suspicion any films taken at close quarters, noting, as I do, the fact that the Boers' rifles and artillery will kill at long ranges.

I went over the Greek battlefields shortly after the war, and I should have found it a very easy matter to have "squared" a few natives to lay as dead upon the field had I needed such pictures, but I did not. Moreover, the guide I employed was the one that accompanied one of our most famous war correspondents to the front, and I value his little tricks too highly to give them away. I did, however, bring a Greek soldier's uniform back with me, and should ever another Greek war break out, I shall probably be the first to send to the illustrated papers an illustration of a Greek in ambush, dead upon the field, and so on. *ad lib.*

Let us now come nearer home. On one of our English churches is a world-famed bas-relief. I went one day to photograph it for a Continental firm. When I arrived at the church, I hunted high and low for my subject, but nowhere could I find it. Very soon the vergers came to my aid, and our conversation was something like this: "May I ask," said he, "if I can help you in any way?" "I am looking for the bas-relief," I replied, "as I want to photograph it." "There it is," said he, pointing to a small piece of stone a few inches square, about fifty feet from the ground, and in such a position that it was absolutely impossible to photograph. I was not the first photographer that had been there and found out the difficulty; the vergers, good men, had got used to photographers, and on my assuring him that I was not an amateur, but a person who had my bread to earn by the art, he took me on one side and said, "I have had a duplicate bas-relief made, and it hangs on the stone wall in my back garden. If you really want a photograph of it, meet me there in half an hour and do the job. No one knows the difference, and all professionals do it." Did I do as the vergers suggested and tip him half-a-crown, or did I build up a scaffold and do the right one? I will leave my readers to judge. That happened a few years ago, and I smile even now when I see pictures (not mine) of it in the London shop windows. This year, when travelling through Italy, I found many vergers there did the very same thing. I could tell of many more tricks, but have said enough—too much some may say—for the present.

RICHARD PENNAKE.

#### LANTERN NOTES AND NEWS.

THE Royal Photographic Society's Second Lantern Meeting will be held at 86, Russell-square on Tuesday, December 5, at eight p.m., when Mr. F. H. Evans will give a lecture upon "Lincoln Cathedral," illustrated by his own slides. Ladies are specially invited.

At the Röntgen Society's Ordinary General Meeting, to be held on Thursday, December 7, at 20, Hanover-square, a paper will be read by Mr. Mackenzie Davidson, M.B.: "Observations on Practical X-Ray Work, with Exhibition of Apparatus and Stereoscopic Skiagrams." Also Mr. J. Moore, F.R.C.S., Hon. Treasurer, will show, with the fluorescent screen, a case of "Bullet in the Brain."

At the Photographic Club, on November 15, Mr. J. Nesbit showed some lantern slides enlarged from Pocket Kodak negatives taken at Earl's Court amongst the Savage South Africans. Seen on the screen, they were of a very presentable appearance, and one especially was an admirable rendering of the smoke of a camp fire amongst the native huts.

At the London and Provincial Photographic Association, on November 23, Mr. T. E. Freshwater showed some examples of Duos du Hauron's method of producing stereoscopic pictures. The picture is printed in red and green inks, one over the other, but something like a quarter of an inch out of register. This is observed through spectacles fitted with green and red glasses, which single out the components of the double image, giving a stereoscopic representation of the subject. Mr. Freshwater also showed on the screen a number of slides of the Transvaal country taken within a few months of the outbreak of war. Coming at the present time, they attracted considerable attention, the views including scenes in Pretoria, Johannesburg, the mine district, and some of the early battlefields.

We append particulars of the Austin-Edwards Lantern-slide Competition: 1. The slide must have been made on an Austin-Edwards lantern plate, and the competitor must state this on entry form, which will be found in every packet of plates, and which must be filled up and sent with the slide entered for competition to the Austin-Edwards Film Works, Warwick. 2. Each slide and entry form must be sent in before the 3rd of the month in which the award is to be made. If it arrives later, it will be entered for the next Competition. 3. The prize slides become the property of Messrs. Austin-Edwards, and all unsuccessful slides will be returned, if stamps and addressed label be enclosed for this purpose. 4. Cheques will be sent to the prize-winners on the 15th of

the month. 5. Slides must be forwarded with all charges paid, and the senders should see that they are securely packed, as, in the event of loss or damage, Messrs. Austin-Edwards cannot accept responsibility. 6. This Competition is open to both amateurs and professionals. The slides will be judged in the lantern, and the awards will be made for the most effective and pleasing results, irrespective of subject, and the decision of Messrs. Austin-Edwards will be final.

Messrs. Percy Lund, Humphries, & Co., Bradford, send us samples of their lantern masks and gummed strips. Of the former there are some twenty or thirty rectangular shapes, while the latter, if mounted by the aid of hot water, have the property of adhering very firmly to the glass. Instructions accompany each box.

Messrs. J. J. Griffin & Sons, of 20-26, Sardinia-street, W.C., send us a sample box of their M. Q. Transparency developer, in tubes. This is their well-known M. Q. developer adapted for use with all lantern plates, though especially suitable for Messrs. Griffin's Gaslyt plates. Clear, brilliant positives of a rich black tone are produced with the developer used at its full strength, whereas warmer colours are obtained by increased dilution and the addition of a small quantity of potassium bromide. The developers are put up in hermetically sealed tubes, and the contents can be got at without shattering the glass, the corks being easily withdrawn.

#### PURIFICATION OF ACETYLENE.

In common with all other writers on acetylene, the *Engineer* states that it has repeatedly urged that, under the existing conditions of calcium-carbide manufacture, and the circumstance that this material is placed on the market in a "commercially pure" state, acetylene is not fitted to be used as an illuminant in dwelling-rooms unless it has been submitted to a rigorous and really chemical method of purification.

The gas can be evolved from carbide in two radically different ways: either by dropping the solid into a large excess of water, the so-called carbide-to-water principle, where the whole interior of the generator is full of water; or it can be prepared by bringing water into contact with carbide, the so-called water-to-carbide principle, where the whole interior of the generator is full of gas. We have already discussed the relative merits of the two processes, and in the present connexion have nothing to do with the matter except in so far as the impurities of the resulting gas are concerned. The normal impurities of crude acetylene, which are of sufficient importance to require attention, are three in number: ammonia, sulphuretted hydrogen, and phosphoretted hydrogen. The two former are very soluble in water, the second is chemically absorbed by lime-water, and therefore it is not surprising that, in carbide-to-water acetylene, phosphoretted hydrogen is practically the sole survivor. In another way also phosphoretted hydrogen is the impurity which gives most trouble to acetylene-users; ammonia and sulphuretted hydrogen have for many years been well-known impurities in illuminating gas. Methods for their extraction have been thoroughly worked out by coal-gas makers, and all that "acetylenists" have to do is to borrow or steal existing processes. In the coal-gas trade, owing to its enormous size, these impurities become actual sources of revenue, and it is necessary to remove them from the gas in such fashion that the sulphur and the ammonia may be recovered in saleable form. By the wildest flight of imagination it cannot be conceived that the ammonia and sulphur in calcium carbide shall ever become peculiarly valuable, therefore the generator-maker is free to employ any processes for their extraction which seem good in his eyes, quite irrespective of the manner in which those bodies suffer during the operation.

In the purification of acetylene, then, there is essentially but one substance to be dealt with, and this merits considerable study: first, because it is very difficult to remove without attacking the acetylene; secondly, because, left in the gas, it is far more objectionable and unhygienic than either or both of the others. On combustion, phosphoretted hydrogen is converted into phosphoric anhydride, which immediately takes up water, and becomes phosphoric acid. Phosphoric acid in a close room produces a whitish haze, misleadingly called by some generator-makers a smoke, and is very irritating to the mucous membrane of the nose and lungs. Traces of sulphuric acid are bad enough, both in this way and in their action on gold leaf; probably phosphoric acid would destroy picture frames and bookbindings to an equal extent, but it stands far beyond its rival as a throat irritant. In passing, perhaps a word of warning may be offered to those persons who are disposed to experiment wildly on the extraction of phosphoretted hydrogen. There are plenty of chemical substances that will oxidise and remove this impurity; the difficulty is to find something that will remove it without simultaneously oxidising the acetylene. Potassium permanganate and barium peroxide extract the phosphorus almost entirely, and some of the sulphur also; but they attack the acetylene, and cause much waste of gas. Potassium bichromate at first removes the phosphoretted hydrogen, leaving the sulphuretted hydrogen behind; but its activity soon falls off, and it is

not of much value as a purifying material. Ferric chloride touches neither the phosphorus nor the sulphur.

From the aspect of purification acetylene has passed through three stages. Originally purification was utterly ignored; next the gas was filtered through glass wool, asbestos, and similar straining materials, which undoubtedly are of service in extracting coke and lime dust, but which cannot be honestly termed purifiers; then some method of real chemical purification was found essential, and more or less intelligently was adopted. Writing in England, we fear the above sentence is scarcely correct; acetylene has not yet passed through the first two stages, it is still passing through them. Several English manufacturers have recognised the necessity of purification, and manfully have struggled to cope with it; others calmly put it on one side, smiling faintly when they are questioned about it; others provide their generators with purifying vessels containing some secret chemical (?) substance, and feel aggrieved when cautious expert writers will not affirm in print that the process is satisfactory.

Practically speaking, there are on the market at the present time three distinct methods of chemically purifying acetylene with varying degrees of efficiency. These are Ullmann's chromic acid, Frank's acid cuprous chloride, and chloride of lime. The primary reagents in the two former processes are solutions, but since liquids are not by way of being conveniently employed in practice, owing to the greater attention required during their utilisation and to the greater loss of pressure in the service when the gas has to pass through a column of reasonable height, they are now being used in the form of solids after absorption in kieselguhr. Ullmann's solidified chromic acid is called commercially "Heratol;" Frank's solidified cuprous chloride is known as "Frankolin."

During the past few months all these processes have been submitted to careful examination in Germany by a number of investigators, whose conclusions respecting the value of the Frank and Ullmann powders all agree substantially with the opinions expressed by Dr. Ahrens, to which we referred on p. 141 of our issue for August 11 last. Dr. Ahrens, it will be remembered, stated that chromic acid and cuprous chloride removed all the phosphoretted hydrogen, but left some sulphur behind, while chloride of lime extracted the whole of the impurities, but introduced others. The new impurities consist of carbonic oxide and certain compounds of chlorine, both sufficiently objectionable in their way; but, on the other hand, bleaching powder is so much cheaper and so much easier to manipulate that it is very desirable to be able to employ it. Moreover, on several occasions lately trouble has arisen with spent chloride of lime; every now and then it heats considerably, and in one case—at Budapest last spring—when the lid of an old purifier was lifted, the mass caught fire, injuring, we do not know how seriously, the man who was going to empty and recharge the vessel. Not altogether without cause, a small scare has sprung up, and chloride of lime has been proclaimed too dangerous a material to be adopted for removing the phosphoretted hydrogen from crude acetylene.

The earliest suggestion for using bleaching powder for this purpose was made by a couple of English, or Scotch inventors—English patent 24,414, 1896; the real credit of working out the idea undoubtedly belongs to Lunge and Cedercreutz. The latter chemists carried out many experiments about two years ago, and said not a word about heating. The same reagent, too, we understand, has successfully been employed, either alone or mixed with some other substances, for quite a long time, by one of the chief English firms engaged in the acetylene business, who, with perfect justice, claim that their material vastly improves the atmosphere of an unventilated room where the gas is to be burnt, and who assert that they have "hundreds of purifiers" in use "giving great satisfaction." Yet a short while ago Professor Vertess published an account of the acetylene installation at the Hungarian tower of Veszprim, in which he said that the burners smoked badly, and the gas exhibited all those defects which are recognised as characteristic of acetylene generated from calcium carbide of inferior quality and burnt without purification. In a later communication to one of the German technical journals, Dr. Ahrens referred to the Veszprim difficulty, and explained, without noticing Vertess's observations, the whole matter. He said that the acetylene of that town was regularly purified with chloride of lime, but that the gas smelt so strongly of chlorine—by this expression we presume he meant that the products of combustion smelt so strongly of chlorine—that the consumers grumbled and threatened to go "on strike," and therefore the purifying apparatus was either temporarily or permanently put on one side. In the absence of the purifying system, Professor Vertess, no doubt, examined the condition of affairs, and very naturally he heard complaints about the choking of the burners. The question thus arises, What is the practical value of chloride of lime as an acetylene purifier, and can it be employed with perfect safety or not?

The whole matter seems to turn, like so many other industrial problems, on several small and apparently insignificant details. If chloride of lime is properly used, it is satisfactory and safe; if it is improperly used, it is a nuisance and a possible source of danger.

Although it is perfectly practicable to do so, it is not convenient, in the small installations where acetylene is the illuminating agent, to use liquid purifying materials. Chloride of lime could be brought into solution, but a slightly damp powder is preferable for various reasons. The acetylene, therefore, must not be too damp when it enters the purifier.

Complete absence of moisture does not appear necessary; it is sufficient that the gas, either in the generator itself or in a separate condenser, shall be thoroughly cooled, and so freed from the greater portion of its water vapour. Ammonia must be removed from the gas before it comes in contact with the bleaching powder, or the violently explosive chloride of nitrogen may be formed. In apparatus of such design, therefore, that the acetylene does not bubble through water—in which, of course, ammonia is enormously soluble—a washing vessel must be put before the purifier, or, if preferred, a vessel holding a little weak sulphuric acid. By remembering these two necessities—absence of excessive moisture and freedom from ammonia—acetylene can be quite safely brought into contact with chloride of lime, and by that material all the impurities will be removed.\* Now, it is said that chloride adds carbonic oxide and chlorine compounds. We cannot imagine that a method of withdrawing the carbonic oxide can be worked out, but we do consider that such a process is really wanted, for the proportion of this highly poisonous gas thus introduced must be extremely minute, and the acetylene after treatment cannot be regarded as in any way comparable to modern coal gas enriched with carburetted water gas, or to carburetted or non-carburetted water gas itself, as regards toxicity. Probably, if this introduction of carbonic oxide had not been noticed by very careful chemists, the presence of the fresh impurity would have remained unrecognised for all time. The chloride compounds are more important, and, fortunately, are more amenable to treatment. By placing a second vessel charged with slaked lime only, after the bleaching powder purifier, almost all the chlorine added by the chloride can be removed without injuring the acetylene; and, as the percentage of chlorine compounds that need extraction must also be small, the second vessel should remain operative for a long while and require very little attention. In a recent investigation of chloride of lime for the present purpose, Dr. G. Benz has asserted that this lime vessel must always be added, and his prescription is endorsed by many other authorities. It most certainly appears a reasonable precaution, and should be followed until some means for preventing the formation of these chlorine compounds—if that be ever practicable—is discovered.

The occasional heating, and the possibility of a fire when the spent chloride is brought into contact with air and light in the operation of recharging the purifier, is an unpleasant phenomenon, but it is equally under complete control, if we may trust, as we entirely do, the latest information on the subject. Ahrens has found that chloride of lime, when used alone, does not exhibit this liability to become hot. It has been the custom with some firms to dilute the bleaching powder with sawdust in order to render it more porous and, by increasing its surface, make it a more energetic absorber of phosphoretted hydrogen. And it is precisely this mixture of chloride with sawdust which is principally liable to heat. Manifestly, there is no peculiar virtue in sawdust as a diluent; a host of other harmless indifferent substances are to be thought of on the spur of the moment. Inasmuch as sawdust has been shown to be harmful, some of these materials must be substituted. Ahrens and Benz both make suggestions: coarsely powdered brick, coke, slag, kieselguhr, &c., will serve. Ahrens also remarks that the chloride must be mixed either with very little water or with a very large quantity of sawdust, to make it quite safe; but, we submit, the total avoidance of the organic matter of wood is distinctly more advantageous.

Quite recently an accident occurred in a mill at Württemberg, where chloride of lime mixed with kieselguhr was being used; the water-seal of the purifier was blown out, the holder bell was lifted, the gas caught fire and suffocated several workmen, who remained unconscious for some hours. After the explosion the purifying material was found to be pasty with water, although it had been introduced into the vessel in a dry state. This catastrophe seems to have been due to the gas passing directly from the generator into the purifier very hot and loaded with moisture; not improbably also the carbide was unusually bad, and the acetylene contained a notable proportion of ammonia. The trouble was aggravated by the employment of an abnormally large purifier, for it is reported that some ninety times more chloride was present than was necessary to deal with the whole of the gas evolved by the generating apparatus.

Thus we see that, by keeping the original acetylene free from too much moisture, removing the ammonia, treating it with chloride of lime, diluted, if necessary, with some inert inorganic substance, and making it afterwards pass through a vessel of slaked lime, more of the impurities in the crude gas are extracted than if the Frank or the Ullmann process be adopted. The operation is said to be simpler for a non-chemical attendant; it is obviously far cheaper. The one disadvantage of the purified gas, its minute percentage of carbonic oxide, is far too trivial to be considered, and no fear need be felt that the half-spent material may become a source of anxiety by overheating, or the spent material a source of danger by actually catching fire.

#### FUN WITH A FLASHLIGHT.

Yes, I've had all kinds of trouble, and I have tried to profit by the troubles of others in flashlight photography.

\* This statement is distinctly admitted by Ullmann and Goldberg in a recent article, and Ullmann is the advocate of chromic acid.

It both amuses and instructs me to see a brother camerist struggle for supremacy with a flash lamp, says Emil Morhardt in the *Photo Era*, a sensitive plate, and fifteen or twenty people who don't want to be in the picture, but have no choice in the matter.

James, the pet of the family, who is having the card party or tiddle-de-winks evening, has announced that he is going to take a flashlight group. To refuse to be in it is to mortally offend Mrs. Hostess, who has done so much for the evening's entertainment—chocolate cake and home-made ice cream. So we silently step into line, brace ourselves against the wall, with a window for background, and a bird-cage tickling our left ear, and await the ordeal.

James puts his head under the cloth, and vainly endeavours to focus on a candle flame which his little sister parades from one end of the group to the other.

"You will have to stand closer together." We are packed like sardines as it is; and, goodness knows, when we get closer, what will some of the blushing maidens do when they find that the new man with the *fleur-de-lis* tie has his head on Miss Modest's shoulder?

We are finally all on, but it is certainly warm, and fully as hard work as going to grocery for your wife. James strikes a match, and it is promptly followed by a miniature explosion, a blinding flash, and the crash of a tin pan falling from the top of the step ladder. As soon as the smoke of battle clears a little, it reveals James hopping around the room, with his right hand in his mouth, or as much of it as he can conveniently stuff in, and Mother Hostess and sister vainly trying to comfort him.

He had used four boxes of powder, and it made a good flash, indeed it did, but it was all lost; for Ed, who has had experience with an AxA snapper, cries out cheerfully, "Why, old boy, you forgot to put in your plate-holder!"

That was one experience. I had another when I tried to take my best girl and myself in the grape arbour, fondly caressing her white figure. Something was wrong somewhere, for all I got was eyes. Still, she forgave the murderous expression, and we are married now, and have studied the thing out together, and bought a flashlight.

We tried it at home the other evening, and it worked finely. So we decided to take it over to Harry's, and take a picture of his wife. All went finely; pose was good, plate-holder in, lens uncapped, and a hard blow at end of rubber tube. Result—*nil*. Another blow, another blank. Poes getting stiff, patience tired, and that fool Jones laughing enough to kill himself.

I explained that the thing got stopped up carrying it over there, and cleaned and reloaded it again, and it works like a charm. It takes some time, though, to smooth out that sensation of disgrace, and dust the magnesium powder from our clothes.

*Moral*.—Don't have any one looking when you take a flashlight, and be sure and blame a failure to the machine.

#### THE GREAT TELESCOPE OF THE PARIS EXPOSITION OF 1900.

AMONG the scientific exhibits at the Paris Exposition of 1900, the great telescope will undoubtedly be the most interesting and important object shown. We are indebted to our contemporary, the *Scientific-American*, for the following description of the instrument:—

It consists of a horizontal tube, 197 feet long, provided with an objective 4.1 feet in diameter. The image of the moon or stars will be sent through this tube by the aid of a Foucault siderostat; that is to say, by a movable plane mirror. The focal length of the telescope of the Yerkes Observatory is but 65.6 feet, so that it will be readily seen that, with a telescope whose focal length was 197 feet, it would be almost impossible to build a dome and mountings which would carry it. It is estimated that a 210-foot cupola would have been required, so the use of a fixed tube and a movable mirror for gathering the image may be regarded as an excellent solution of a mechanical difficulty. The siderostat is undoubtedly the most interesting part of the instrument. It consists of a large cast-iron frame, and is provided with clockwork and devices for causing the mirror to follow the celestial object which is being viewed. The frame is now under construction at the establishment of M. P. Gautier, a distinguished manufacturer of instruments of precision. It is 26½ feet long, and the height is the same as its length. It is provided with six levelling screws, which enter into sockets fixed upon a stone base 5.57 feet high. The hour axis is actuated by clockwork through the aid of tangent screws. The part of the instrument toward the south carries the mirror, which is mounted in a cast steel cell, lined with felt in order to prevent any contact of the mirror with the metal. The equilibrium of the mirror and cell is obtained by means of levers and counterpoises. The base of this mounting floats in a reservoir 6½ feet in diameter, and containing about 16 gallons of mercury. Owing to the application of the principle of Archimedes, the movable parts will be relieved of nine-tenths of its weight. The system of the levers and counterpoises is so well arranged that all of the movable parts can be actuated by hand even without the aid of the mercury. The total weight of the siderostat is 99,000 pounds; the moveable part weighs 33,000 pounds, of which the mirror and its cell weighs 14,740 pounds. A weight of 220 pounds is sufficient to actuate the clockwork.

The mirror has a diameter of 6.56 feet; it is 10.63 inches thick, and its weight is 7920 pounds, and it was naturally the most difficult part of the apparatus to construct. The glass was cast at the Jeumont Works, and a special furnace was constructed capable of holding 22.4 tons of glass. When the time for casting arrived, the mould, 6.72 feet in diameter and 12 inches thick, was brought to the furnace upon a truck, and then, after being filled, was introduced into the furnace, which had been raised to a high temperature. It was then walled up in this furnace, and the cooling required a month. Notwithstanding all the precautions, several of the discs that were cast broke in pieces with a loud noise. The transportation of such a huge disc of glass to Paris was a difficult matter, and a special train carried it there without stopping. A crane deposited the gigantic block on a waggon, and it was carried to the optical establishment at night, in order to have a clear roadway.

To obtain a fine disc of glass of such dimensions was, of course, difficult, but to give it a perfectly plane surface was a much greater one, and M. Gautier is to be congratulated upon the success which he has attained in performing this difficult operation.

The polishing machine was placed in a special shop, protected as much as possible from variations in temperature by a double wooden wall. The grinding apparatus consists essentially of a large cast-iron plate, covered with an inch of flannel, upon which the glass disc was carefully laid.

This plate revolves slowly around a vertical axis by gearing, the whole being stepped in a cone. Above there is a stationary circular bronze rubber, 47½ inches in diameter, which is given a reciprocating motion by a slider, thus passing across the face of the mirror, travelling in a circle beneath it. The perfect revolution of the plate and the accurate adjusting of the slides and their parallelism resulted in the production of a perfect mirror. It required three months to adjust the slides alone. The grinding of the mirror was done with a mixture of emery and water. During this operation a workman always stood at a respectful distance from the apparatus, so as not to change the temperature of it. From time to time he injected a mixture of emery and water by means of a syringe into a channel running through the grinding plate and ending at the centre. This work was carried on generally from two to five o'clock in the afternoon, the time of day when the temperature does not change perceptibly. The entire morning was devoted to the cleaning of the machine and to the verification of the parallelism of the grinding plate with the surface of the mirror, an operation which was performed with four scales, which were accurate to one one-thousandth of a millimetre.

As the grinding proceeded, finer and finer emery was used, and the closer the grinding plate was brought to the surface of the glass. With the finest emery the distance between the plate and the glass was 0.008 inch. The grinding lasted eight months, and was followed by the operation of polishing, which required two months. The lower surface of the polishing plate was covered with a sheet of albumenised paper, like that used in photography, but unsensitised. The workmen spread upon this paper a small quantity of the finest Venetian tripoli, and as much as possible was removed with a soft brush. The distance between the rubber and the surface of the glass was 0.0012 of an inch.

This method of treatment, notwithstanding its delicacy, produces enough heat to render the mirror slightly convex, and cause it to draw away more strongly in the centre, so that, upon cooling, it was hollowed at this point. In order to surmount this difficulty, the slides were given a curve, of which the pitch was 0.4 of an inch. The heat was diminished by operating the machine for a minute, and then stopping for a quarter of an hour. When the hand is applied to the mirror, there occurs an extension of 0.0012 of an inch, which is sufficient to distort completely for four or five minutes the image of the flame of a lamp placed at one side of the plate and observed from the other with a small telescope arranged for the purpose. The next operation to be performed is the silvering, and, of course, it will have to be silvered anew from time to time. The mirror protrudes 5.4 inches from its tube or cell, which will be made to swing so as to bring the surface to be silvered underneath. The reservoir containing the bath will be lifted by means of a winch until the mirror enters it at a proper depth. When the operation is finished, the reservoir will be lowered, and the silvered surface turned upwards, and the mirror readjusted in its cell.

The images of the mirror, which are transmitted to the focus of the objective, may be examined directly by means of an eyepiece, or they may be thrown upon a sensitised plate, or projected upon a screen placed in a hall set apart for that purpose, so that several thousand people will be able to examine the celestial object at the same time. The tube of the telescope is a steel plate three-quarters of an inch in thickness and five feet in diameter. It is made up of twenty-four sections joined with the aid of bolts. These sections, when all mounted, will rest upon a cast-iron base, supported by stone columns. It is arranged so as to slide to take up the expansion and contraction. The tube plays no part in the formation of the images, nor does it serve for supporting the objectives in the eyepiece, but it prevents dust from introducing itself between the essential parts of the apparatus.

One of the objectives is designed for visual observations, and the other for photographic work. Both are mounted upon a carriage made to roll upon rails so that either of them may be easily placed in position before

the tube. The weight of either of these objectives, without its mounting, is about 1295 pounds, and, with the mounting, 1980 pounds. Each of the crown glasses is carried by rollers, so that it may be separated from the flint glass in order to render the cleaning of each disc easy. The lenses will cost \$120,000.

The discs were cast by Mantois, of Paris. Great attention was paid to the casting of the glass. Specimens of the glass were constantly taken out during the heating and examined with a lens under different conditions of illumination in order to judge of the degree of purity which they have reached. After several specimens have been found to be free from bubbles, the temperature is reduced, the glass thickens, the crucible is opened, and a certain portion of the surface is skimmed off to get rid of impurities. The glass is then stirred, and the cooling is allowed to proceed rapidly for five or six hours until the surface of the glass emits a well-defined sound when it is struck with an iron bar. After this step it is necessary to proceed with annealing. The furnace is walled up, and a cooling is allowed to proceed which requires from four to six weeks. When the crucible is opened, the glass is found to have been broken into pieces of varying sizes. In order to obtain a 792 pound flint-glass lens it is necessary to find a block which weighs nearly 1300 pounds, and, such a block having been found among those in the furnace, it is removed and placed upon a car. Slabs of glass are sawed from two parallel sides in order to obtain polished surfaces that facilitate a perfect examination of it.

The striae in the surface are removed, and, if after this, the block exhibits any defects situated at such a depth that they cannot be removed, it is submitted to a moulding which changes its form and brings the chief defects near the surface. The block is placed in a mould of refractory clay, and put into a furnace and heated to 800° to 900° C. By this means it becomes slowly heated and softened until it assumes the form of the mould, but it must not become fused, or the whole operation must be gone over again. If the outcome of the process is successful, the glass is slowly annealed, and is then taken from the mould and examined anew. If any defects deep in the glass are seen, a second operation is begun with a mould of another form. Finally, when the glass is very pure and perfect, another and final moulding produces the plano-convex lens. After this comes another heating and cooling, which takes two or three weeks.

At this point the glass discs are taken to the establishment of M. Gautier, where the surfaces are polished with a device like that used in polishing the mirror, except that the slides have the curve that is to be given to the disc. A long time is required in polishing out the small imperfections, and finally the lens is entirely corrected and ready for mounting.

The tube which carries the eyepiece is supported by four wheels rolling upon rails. It is attached to the telescope by an adjusting screw, 4.92 feet in length, which serves for putting it in focus. In the interior of this tube another is mounted upon rollers. This inner tube is 3.54 feet in diameter, and is moved circularly by means of clockwork through the medium of a tangent screw which fits into the teeth of a circle fixed to its outer extremity. In this first circle, which moves upon four rollers, is a second circle, which carries two guides, and in which slides a carriage having a travel equal to a little more than two minutes of time. This is actuated by a screw which causes the motion in another clockwork. This carriage is provided with a system of frames having rectilinear motion, that permits of giving the eyepiece different positions. The upper frame is so arranged that it may receive devices for photography, micrometry, spectroscopy, or a projecting apparatus. The exact location of the telescope has not yet been determined upon, but it will be at the service of the Exposition, and will probably be placed somewhere where the atmosphere is purer than that of Paris.

#### THE AUSTIN-EDWARDS LANTERN PLATE.

MANUFACTURED BY AUSTIN EDWARDS, WARWICK.

FROM Mr. Austin Edwards we have received samples of two new kinds of lantern plates he is introducing—red label for ordinary dark-room working, blue for gaslight development. The following instructions give the characteristic features of the latter plates, with the method of their manipulation:—They can be developed with an ordinary pyro-soda developer as used for negatives, and will yield rich, warm, velvety tones of the precise tone best suited for lantern-slide work—liquid in the shadows and transparent in the high lights. The chief advantage of the blue label plates is found in the fact that they are so little sensitive to yellow light that they may be used without a dark room, all operations being carried on in gas or candle light, while at the same time they are not too slow to be exposed by gaslight, working close to the flame.

#### EXPOSURE AND DEVELOPMENT OF THE BLUE LABEL PLATES.

*Exposure.*—The plates may be exposed under a negative in an ordinary printing frame, either to subdued daylight, magnesium, or gaslight. The exposure will vary according to the colour desired in the finished transparency. For black tones a shorter exposure is required than for warm tones, about one to two minutes at four inches distance from the flame of a gas-burner will be sufficient for black tones. The best method of

exposing the plates is to use burning magnesium ribbon, as this gives the power of easily regulating the exposure according to the density of the negative. Thus, with a negative of average density, one inch of ribbon burnt at twelve inches from the printing frame will give a good black tone. With a thin or weak negative the distance should be increased. For warm tones use from four to six inches of magnesium ribbon at the same distance.

*Development.*—They may be safely developed and handled by candle or gaslight, no dark room being necessary. It is well to keep the plates shielded from direct light, and work at some distance (say, six feet) from the light while developing.

#### PYRO-SODA DEVELOPER, GIVING ANY TONE FROM BLACK TO CRIMSON.

##### Stock Pyro Solution.

Pyrogalllic acid .....	1 ounce.
Nitric acid .....	20 drops.
Water .....	8 ounces.
Add the acid to the water before dissolving the pyro.	
No. 1.—Stock solution .....	2 ounces.
Water .....	20 "
No. 2.—Sulphite soda .....	2½ ounces.
Carbonate soda .....	2½ "
Bromide potass. ....	10 grains.
Water .....	20 ounces.
No. 3.—Bromide amm. ....	2 ounces.
Water .....	20 "

For black tones use equal parts 1 and 2, exposure about one inch magnesium at twelve inches. Time of development, about two minutes.

For brown tones use two parts No. 1, two parts No. 2, and one part No. 3, and double the exposure. Time of development, about three minutes.

For red tones use equal parts 1, 2, and 3, and again double the exposure. Time of development, about four or five minutes.

We hope to give the results of a practical trial of the plates on a future occasion.

#### COLOUR PHOTOGRAPHY.—THE McDONOUGH PROCESS.

At the Columbia Photographic Society, Philadelphia, on October 16 and 18, the editor of the *Camera*, assisted by Mr. P. A. Mitchell, gave a demonstration on "Colour Photography by the McDonough Process of Colour Photography." The entire method of the work was fully explained, over fifty slides (made by the process) shown, and the manner of making the exposures, &c., demonstrated. The following are extracts from Mr. Chambers' lecture:—

"Colour photography, which has been much in experiment in this country and abroad for years past, has now practically reached a state of perfection. Few of us realise the difficulties encountered by the inventors of the processes on the market, and the most simple, the one easiest understood by the amateur, is the one we here demonstrate this evening, the McDonough process. The expense in using this is very small, the cost of fitting up a camera but a trifle, and the results gratifying. The method of photographing colour by this process is on the scientific principle of the mixed coloured light. Many scientists have demonstrated that the elementary or primary colours of a ray of sunlight are red, green, and blue, and the mixture of these on the retina of the eye produces the colour sensation of white, and all the various shades of colour are the resultant of these three fundamental sensations. In the McDonough process the essentials employed for making a negative are a Taking Screen, Chromatic Balance Shutter, and Erythro dry plates, the latter being the Seed 26 x normal plate orthochromatised for the red wave-lengths of light. The Taking Screen is a plate of glass coated with gelatine emulsion and ruled in red, green, and blue parallel lines from 300 to 600 to each inch, in the order named. This Taking Screen is adjusted in a metal frame inside the camera, and attached to a lever conveniently placed outside the box, where it can be used to throw the Taking Screen in contact with the Erythro dry plate when slide of plate-holder is withdrawn to make exposure. The Chromatic Balance Shutter, which is placed on hood of lens, is made with sectors of lemon-yellow and orange-coloured glass or mica, actuated by a metal finger, and its office is to balance the varying conditions of illumination, there being less blue in bright sunlight than with cloudy skies, or when photographing indoors. The adjustment of the shutter for the difference in illumination is by moving the metal finger to open or close the coloured sectors. A negative made under conditions noted will show in duplicate the lines of the Taking screen, but with different degrees of opacity according to the light value that has fallen upon the silver haloids of the sensitised Erythro dry plate through the Taking Screen and Chromatic Balance Shutter. Their colour value lines are transferred to the positive, which is made in the ordinary manner, by superposition, using any good transparency dry plate, and the transparency or positive so obtained is placed in contact with a Viewing Screen, which is made exactly like the Taking Screen, only on thinner glass, the red, green, and blue lines corresponding in number to those used on the Taking Screen, and the lines on positive or transparency and Viewing Screen being in parallel or

register, the colour appears as in the object photographed. When this is done, fasten the two together with spring clips, bind the edges with adhesive strips, and the positive is ready for the window or projection in the lantern.

"Several things are peculiar to the McDonough process regarding the matter of development. There is no choice as regards a certain developer being used—any kind may be employed; the only thing is that it is necessary to use it slightly weaker, and with reduced quantity of alkali; that is to say, if you were to use a developer requiring 4 ounces of water, you would add fifty per cent. more, making it 6 ounces. Then, if the completed mixture would make, say, from 8 to 10 fluid ounces of developer, we add ½ an ounce of a ten per cent. solution potassium bromide; we do this owing to the extreme sensitiveness of the plate, and in order to prevent fog from over-exposure and development. I might say that, in all my experiments with the process, I have not had one fogged plate in my developing, and, in cases where I have deliberately over-exposed, I have been able to control it, and secure a perfect negative by the use of my bromide. The Erythro plate employed is extremely sensitive to the red light in the dark room; my plates were developed in practical darkness, and after two tests I found that I could employ time developments and secure absolutely perfect results. The other evening I purposely tested one of these plates under the red light; one-third of the plate was covered, and the other two-thirds developed with the red light shining upon it. The result is that two-thirds of the plate exposed to the red light is most beautifully fogged. The one-third of the plate which was partly shielded does not show this trouble. In my method of exposure I found a Wynne meter a great boon; in fact, I would have been totally at sea without its aid at first, as these plates require a more lengthy exposure than the normal Seed's 26 x, owing to their special preparation.

"The International Colour-photo Company, of Chicago, to whom I am indebted for the manner and form of testing this process, furnished me with a formula for developing my transparency plates. I not only find this excellent for my work with the colour-process transparencies, but it is also fine for ordinary slides. I will give it to you:—

Water .....	24 ounces.
Hydroquinone .....	180 grains.
Sulphite soda (crystals) .....	5½ ounces.
Formaldehyde (40 per cent.) .....	3 drachms.

"This is the stock solution. For use, to the 4 ounces of the stock solution add 2 drachms of ten per cent. bromide of potassium. This may strike you as rather peculiar, as no alkali is mentioned in the shape of soda or potash; but the formaldehyde fills all the requirements of an alkali, and it also prevents shrinkage in the films."

#### THE WOODBURY LANTERN SLIDES.

Eyre & Spottiswoode (Woodbury Department), Great New-street, E.C.

The always-admired qualities of lantern slides by the Woodbury process, which for many years past has been considered, by those best competent to judge, as the most charming method for the production of transparencies for the optical lantern, has once again been demonstrated to us from an inspection of a series of slides made from historical pictures illustrative of the principal events of Her Majesty's reign. All the beauties of the process are well brought out in this series, to which Messrs. Eyre & Spottiswoode are constantly making additions, and thus, in a short space of time, the trade will have at its disposal a wide selection of Woodbury slides for the purpose of introducing to the notice of those whose business it is to give optical lantern-slide entertainments.

We append extracts from Messrs. Eyre & Spottiswoode's lantern lecture circular for the season 1899-1900, which gives detailed particulars of the sets already available. We can say of a Woodbury lantern slide that it is a thing of beauty and a joy for ever.

Four lectures have just been published, entitled:—

1. The Romance of a Reign; or, Victoria, Queen and Empress.
2. Through Shot and Shell; or, Nelson and His Times.
3. Gems from the Galleries; or, An Evening with the Masterpieces of the World's Art.
4. The Bible and the Monuments; or, Parallels to, and Illustrations of, the Bible Story.

Messrs. Eyre & Spottiswoode have in immediate preparation a new lecture, entitled "The Boer War Day by Day." Each set consists of about sixty slides, and a lecture is supplied.

#### THE REAL DICKENS LAND.

At the New Lecture Hall, East Finchley, on Monday, December 4, 1899, at eight o'clock, a lecture, entitled "The Real Dickens Land," will be given by Mr. H. Snowden Ward, editor of the *Photogram*, and author of *Shakespeare's Town and Times*.

Every place that is mentioned has been visited, carefully studied, and photographed, and with the principal scenes in London the lecturer is from long and intimate acquaintance.

The lecture will be illustrated by about 120 lantern slides from negatives specially taken by Mrs. Catherine Weed Barnes Ward.
